SUPPLEMENT TO "THE ELECTRICIAN," MAY 1, 1896.

1735
Electrical Equipment

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

VOLUME XXXVI.

FROM NOVEMBER 1, 1895, TO APRIL 24, 1896.

LONDON:
Printed and Published for the Proprietors by GEORGE TUCKER, at the Offices of "THE ELECTRICIAN," Salisbury-court, Fleet-street, E.C.

1896.

INDEX TO "THE ELECTRICIAN."

VOL. XXXVI.

97013
621.305
El 222

General Alphabetical Index.

Italic figures denote that the subject-matter is in the "Leading Articles" or in the "Editorial Notes."

A

Académie des Sciences, 305
Accidents, (*Bankside*) *346*, (*Bilbao: Tramway*) 679, (*Car: Cleveland*) 109, (*Chatham*) 177, (*Cheltenham*) 245, 402, *535*, 548, (*Coventry: Car*) 401, (*Flywheel*) 3, 211, 633, 715, (*Frankfort*) 274, (*Hamburg: Tramway*) 715, (*Hampstead*) 402, (*High Pressure Stations: Mr. Fyfe*) *843*, (*Huddersfield*) 334, (*London Electric*) 305, (*Portrush*) 8, *10*, (*Silesia*) 334, (*Southport*) 537
ADDENBROOKE, G. L.:
High-Voltage Lamps and their Influence on Central Station Practice, 691
ALLEN, H. N.:
Fundamental Magnetic Units, 849
Graphic Representation of Vector Potential, 752
Alternate-Current Plant at Dover, 376
Alternating and Continuous Currents on the Same Circuit, 881
Alternating-Current Curves, The Form Factor of: by Dr. J. A. Fleming, 338
Alternating-Currents, Rapidly, Resistance of Wires to, 4
Alternating-Current Systems of Electric Supply, The Regulation of Pressure in and the Reduction of Light Load Losses in: by E. W. Cowan and A. Still, 762, (*Discussion*) 797. (*See also pages 748, 779*)
Alternator, The 1,000-unit Deptford, 147
"Aluminium and Electrolysis," 177
Aluminium Solders, 211
Aluminium Works of the Pittsburg Reduction Company at Niagara Falls: by Orrin E. Dunlap, 374
American Institute of Electrical Engineers, (*Membership*) 469
APPLEYARD, R.:
Action of Sulphur Vapour on Copper, 189
A Direct-Reading Platinum Thermometer, 189
Resistance and its Change with Temperature, 189
Arbitration, London Chamber of, 287

Arc Lamps—
Crompton Arc Lamp Patent, 368
"I.R." Lamp, 223
Jandus Lamp, 11, (*Report*) 575
Marks' Ventilated Enclosed Lamp, *434*
Public Lighting by Arc Lamps, *747* [Blondel], 757, 790, 820, 853
Street Lighting by Arc Lamps [Blondel], 13, 39, 89
Series Choking-coil System, *176*

Arc Lighting by a Tramway Power Station, 759
Arc Light, Penetrating Nature of, 645
Arcs, Researches on Alternate-Current, *243*, *609*, [Görges] 230, [Fleming] 247, 630, [Arons] 437
Arc Spectra, 802
Arc, The Electric: by Hertha Ayrton, 36, 225, 539
Arc, The Sahulka Effect in, 646
Arc, The Three-Phase, 811
Argon, 262, 645
Argon and Helium, On the Behaviour of, when submitted to the Electric Discharge: by Prof. W. Ramsay and Mr. J. N. Collie, 863 (*See also page 844*)
Armour Plates, Local Annealing of Hard Faced: by Hermann Lemp, jun., 119
ARMSTRONG, Prof. H. E.:
Nature of Chemical Change and the Conditions which Determine it, 464, 518, 545
ASCHKINASS, E.:
Change of Resistance due to Electric Rays, 864
ATKINSON, Ll. B.:
Distribution of Power in Collieries, 388
Atom, The Relation between, and the Charge of Electricity Carried by it: by Prof. J. J. Thomson, 322, 344. (*See also pages 304 and 469*)
Audit, The Law of, *333*, *658*
AYRTON, HERTHA:
The Electric Arc, 36, 225, 539

B

Bacterial Toxines, Influence of High Frequency Currents on, 612
BAILY, Prof. F. G.:
The Hysteresis of Iron in an Alternating Magnetic Field, 116
BATHURST, F.:
The Electric Wiring Question, 199

Batteries (Primary)—
Clark Cell, *643*, [Fisher], 647
Coehn Carbon Consuming Cell, 679, *747*, 756
Jacques' Carbon Consuming Cell, 768
Lessing Dry Cell, *573*, 589
Voltaic Cell, Centenary of, 845

Batteries (Secondary)—
Accumulator Tests in Germany, 178
Accumulator Car Trials in New York, *210*
Boston Edison Station, 378
Blot Accumulator, The, 301
Ford-Washburn Cell, 782
Lead Batteries, A Contribution to the Theory of [Löbb], 819
Persulphuric Acid, *574*
Theory and Construction of Secondary Batteries, Advances in [Zacharias], 818

BAXTER, W. (JNR.):
Direct Connection of Electric Motors with Machines of Various Types, 827
BENNETT, A. R.:
Municipal Telephony, 79, 285
The Government of Norway and the Telephones, 278
Berlin Suburbs, Electricity in, 72
Bicycle Lamp, 434
BLONDEL, ANDRÉ:
Street Lighting by Arc Lamps, 13, 39, 89
Public Lighting by Arc Lamps, 757, 790, 820, 853
Board of Trade, (*Electric Light Rules: Conference*) *69*, *122*, 127, (*Expert "Low Pressure" Committee*) 218, *224*, 245, (*Revised Rules: Issue*) 487, *501*
Boiler, Hornsby, 407
Boiler Practice (*English Stations*) *780*, *796*, (*Philadelphia Edison Station*) *333*,
BOLTZMANN, Prof. L.:
Prof. Röntgen's Epoch-making Discovery, 447
BOSE, Prof. J. C.:
On Double Refraction of the Electric Ray by a Strained Dielectric, 290
On a New Electro-Polariscope, 291
On Polarisation of Electric Rays by Double Refracting Crystals, 289
BRADLEY, CHAS. S.:
Phasing Transformers, 43
Brighton Curves, 517
British Association, 611
British-Association Speakers, 143
BURSTALL, HENRY R. J.:
The Electric Lighting of Edinburgh, 15, 57

C

Calcium Carbide, 335, *368*, 372, (*Spray and Niagara*) 815
Cambridge, Engineering at, 178
Canal Boats, Electric Propulsion of: by Orrin E. Dunlap, 88
Canal, Burgundy, Electric Haulage on, 305, 369
Canadian Society of Civil Engineers, Code of Ethics of, *644*
Candle, The Dibdin, *468*
Capacity and Lead, *779*
Carborundum, 33, *70*, (*Works at Niagara*) 86
CARDANI, Prof. P.:
Thermal Phenomena of Discharges in Derived Circuits, 292
CARTER, E. TREMLETT:
Motive Power and Gearing, 5, 145, 213, 306, 477, 812
Cycles, Various Gas Engine, 214
Gas Engine Governors, 213
Gas Engine Starters, 213
Gas Engine Testing, 306
Gearing in Relation to Electric Power Station, 812
Ignition Apparatus, 146
Oil Engines, 477
Otto Cycle, 5
Catalogue Filing at the Patent Office, 503
Cathode Rays, (*Absorption*) 110, (*Luminescence*) 72, [Jaumann] 487, [Perrin] 523, [Puluj] 689
Cement and Concrete, On the Electric Conductivity of: by Dr. St. Lindeck, 788. (*See also page 779*)
City, Electric Lighting of the Side-Streets of 826

Central Stations—
American Stations, Cost of, 715
Boiler Practice (*England*) *780*, 796, (*Philadelphia Edison Station*) *333*
Brighton Curves, 517
Bristol, 613
Cambridge Curves, 195
Capital Expenditure in England, 436

Central Stations (*Continued*)—
Condensing Plant, Surface, at Newcastle, *32*, [W. Cross] 45
Dover, *810*
Edinburgh [Henry R. J. Burstall], 15, 57, [Prof. Kennedy's Report] *209*
English *v.* German Practice, *433*
French Provincial Stations, 436
Massachusetts Central Station Finance, 668
Paris, 72
Water-Power Stations in the United States, 781
Chemical Change, Nature and Conditions of: by Prof. H. E. Armstrong, 464, 518
Chemical Fact and Theory, *482*
Civil Engineers, Institution of, 71, 304
Classification of Physical Experiments: by E. E. Fournier d'Albe, 721. (*See also page 715*)
CLERK, DUGALD:
Recent Developments in Gas Engines, 480
"Coherer," The Bose, *273*, 291
Collieries Distribution of Power in: by Ll. B. Atkinson, 388
Competition in Electric Supply, 728
Concentric Wiring: by Sam Mavor, 161
Conduits, Cast-Iron and Stoneware, 653
Consumer's Point of View, The, *380*
Contemporary Electrical Science Notes, 4, 72, 110, 144, 178, 212, 246, 275, 336, 369, 538
Copper, Action of Sulphur Vapour on: by R. Appleyard, 189
Correspondence—*See* Appendix to Index.
COWAN, E. W., and STILL, A.:
Regulation of Pressure and the Reduction of Light Load Losses in Alternating-Current Systems of Electric Supply, 762, (*Discussion*) 797
Crookes' Apparatus, On a: by H. Pflaum, 853
CROSS, W.:
The Surface Condensing Plant at the Newcastle and District Company's Electric Light Works, Newcastle-on-Tyne, 45
CUNINGHAM, G. C.:
The Electric Street Railway System of Montreal, Canada, 592
Current Density for Electric Light Mains, The Economical: by James Whitcher, 723. (*See also page 715*)

D

Deptford, The New Steam-Dynamo at, *141*
Deptford 1,000kw Alternator, Foundation of, 856
Dielectrics, Energy Loss in: by P. Gasnier, 7
Diffusing Globes, (*Fridureau*) 612, (*Holophane*) *644*
Dinners (*Ansell*), 130, (*National Telephone Staff*) 701
Discharge Phenomena in Rarefied Metallic Vapours: by Prof. E. Wiedemann and G. C. Schmidt, 851
DUNLAP, ORRIN E.:
Aluminium Works of the Pittsburg Reduction Company at Niagara Falls, 374
Electric Propulsion of Canal Boats, 88
The Carborundum Works at Niagara Falls, 86
Dust Destructors, The Use of, as Steam Producers for Electricity Supply Stations: by E. Manville, 254, (*Discussion*) 257
Dust Fuel, 258

E

Earth-Air Electric Currents in the United Kingdom, The Existence of Vertical: by Prof. A. W. Rücker, 293
Edinburgh, Electric Lighting of: by Henry R. J. Burstall, 15. (*See also page 209*)
Edison Effect, The: by Dr. J. A. Fleming, 801. (*See also page 748*)
Efficiency of a Generating Plant, 3
Electrical Engineers, Institution of, (*Annual Dinner*) 262, (*Annual General Meeting*) 259, (*Balance Sheet*) *714*, *747*, 769, 771 (*Benevolent Fund*) 368, (*Council for 1896*) *229*, (*Discussion*) *643*, (*National Defence*) *400*, 421, 446, (*Presidency*) *69*, *175*, (*Reform*) *243*, *273*, *853*
Electric Fuse Train, 336
Electric Lighting Acts, Proposed Amendment to, 109, *156*
Electric Lighting and Traction Notices, 196, 321
Electric Supply in Germany, 684
Electromagnetic Theory: by Oliver Heaviside, 34, 111, 179, 276, 349, 404, 576, 716, 847
Elektrotechnischer Verein of Berlin, 469

Digitized by Google

Traction—
Accidents, A Mode of Preventing, 434
Accumulator Car, (*Hanover*) 335, (*Trials in New York*) *210*, 222
American Mistakes in Track and Overhead Construction, *334*
Anderson Closed Conduit System, 402
Belfast, (*Report of Committee*) *309*
Bilbao, Accident, 679
Bonds, Tests of Rail, 699
"Booster" System, 121, (*Patent Litigation*) 611 [Scott] 734
Boston West End System, Annual Report of, 246
Brighton-Rottingdean Electric Railway, *46*, 53, 54, *108*, 245
Burt Conduit System, 287
Cairo, 781
Canal Boat Haulage, (*France*) 305, 369, (*United States*) 88, 680
Central London Railway, 109
Chicago Elevated Electric Railway in a Snowstorm, 294, 611
Coal Consumption on French Lines, 469
Combination Generators at Akron, 868
Conduit Systems, (*Burt*) 287, (*Connett*) 177, *Murphy-Pierce*) 246, (*N.Y. and Washington*) *536*, (*Paris*) 684
Continuous Rail, The [McCulloch], 310
Coventry, 118
Dublin-Dalkey Line, 882, 574
Dublin, (*Southern Tramways*) 177
Earth Return, The, 33
Electrolysis at St. Louis, 611
European Statistics, 852
Finance, American Street Railway, *84*, 143
Gas Cars at Dessau, *176*
Gas Engine Plant, 53, 424
Generator, A 1,500-kilowatt, 356
Generator, How to Throw on, 229
Glasgow, 845
Hamburg, Accident at, 715
High Railway Speeds, *108*
Jungfrau Line, 665
Leeds, 326, 434
Light Railways, (*Association*) 144, (*Bill*) *609*, 632, (*Conference*) 117
Locomotives (*Belt-line Tunnel*) 144, 681, *536*, (*Heilmann*) *557*, 612, (*Huron Tunnel*) 3, (*Westinghouse-Baldwin*) 611
London County Council and Overhead Trolley, *535*, 549
London Tramways Question, 845
Lugano, 589
Montreal [Cuningham], 592
Motormen, A Mathematical Method of Evaluating, *210*
Motor Ventilation, 645
Mount Lowe (Cal.) Railway, *844*
Murphy-Pierce Sectional Conductor System, 246
Nechells Line, The, *51*
New-York, Rapid Transit, 786
Niagara Falls, Electric Lines Supplied from, 470, (*Lewiston*) 258

Traction (*Continued*).—
Notices, 196
Parshall's (Mr.) Lecture at the Society of Arts, *536*
Physical Institutes, Dr. Frölich's Device for Protecting, 353
Portrush Accident, The, 8, *10*
Rail Return, Proper Resistance of, *70*
Railways, American, The Use of Electric Traction on, 143
Rapid Construction, 143
Rhine, The, Railway over, 644
Roadbed Construction by Electrical Engineers, *142*
Roadbed Materials, Insulating Properties of [Lindeck], 788
Rome, 645
Sectional Conductor Systems, (*Burt*) 287, (*Murphy-Pierce*) 246, (*Westinghouse*) 1, 53
Siemens and Halske "Bar" Contact, 407
South Staffordshire Tramways, 304
Sprague Electric Railway Company, 334
St. Louis, Electrolysis at, 611
Swansea Scheme, 245
Teheran, 304
Telephonic Disturbances *535* [Preller], 333, [Wietlisbach] 725
Third Rail Patent in the United States, 149
Three-phase Transmission, *2*
Traction, Power and Light Stations, 352
Trolley Patent, Van Depoele, Sustained, 294
Trolley System, Novel Application of, 435
Trolley Work, 177
Underground *v.* Surface Railways, *843*
United Kingdom, Electric Railways and Tramways in, 321
Walthamstow and Epping Forest Railway, *367*, 369
Westinghouse Electro-magnetic System, *1*, 53
Westinghouse Side Trolley, 353
Zürich, 244

Transformers—
Behaviour of Transformers under the Influence of Alternating Currents of Different Wave Forms, *107* [Roessler], 124, 150, 194, 219
Cantor Lectures, Dr. Fleming's, 305, 403, 436, 470, 504
Litigation in Italy, 845
Phasing Transformers, 32 [Bradley], 48
Tanning, Electric, 71
TAPLEY, W. H.:
Electrical Plant in the United States Printing Office at Washington, 490
Technical Societies, The Works of, 72
Temperatures, High, Determination of, by the Meldometer: by Prof. Ramsay, 594
THOMSON, Prof. J. J.:
The Relation between the Atom and the Charge of Electricity Carried by it, 322, 344
THOMSON, Prof. ELIHU:
Dielectric Strength of Oils under Alternating Potentials, 591
Stereoscopic Röntgen Pictures, 661
Tinfoil Gratings, Alteration of Resistance of, by Electromagnetic Waves, 187, 212, 864

TROTTER, A. P.:
Comparative Cost of Gas and Electric Lighting, 197
Transmission of Power, (*Canada*) 470, (*Guatemala*) 305, (*Niagara: Buffalo*) 274, (*Niagara Power House: Additions*) 845, (*North Shields Docks*) 213, (*Portland: Oregon*) 144, (*Rhone*) 750, (*Silverton Col.*) 4, (*Zufikon-Bremgarten*) 751
Turbine, The De Laval Steam, 279, 335, 391, 588

U

Units, The Rational System of, 211

V

Vector Potential, The Graphic Representation of: by H. N. Allen, 752. (*See also page 745*).
Vegetation, Electricity and, 513

W

WALLER, A. D.:
Observations on Isolated Nerve, 862
Water Power, Utilisation of, (*Canada*) 470, (*Guatemala*) 305, (*Niagara*) 183, 274, (*Niagara Power House: Additions*) 845, (*Portland: Oregon*) 144, (*Rhone*) 750, (*Sarpsfos*) 401, (*Silverton: Three-Phase*) 4, (*Stations in U.S.*) 781, (*Worcester*) *609*, 633, (*Zufikon-Bremgarten*) 751
Water Softener, Archbutt and Deeley's, *70*
Waves, Electromagnetic, (*Double Refraction*) 92, (*Longitudinal*) 417, *535* [Lodge] 433, [Jaumann] 417, [Boltzmann] 447, (*Tinfoil Gratings*) 187, 212, 864, [Bose] *273*, 289
Westinghouse-General Electric Combination, 736
Wheatstone Bridge for the Determination of Low Resistances, An Addition to: by J. H. Reeves, 689
WHITCHER, JAMES:
Economical Current Density for Electric Light Mains, 728
WIETLISBACH, DR. V.:
On Telephonic Disturbances caused by High-voltage Currents, 725
WIEDEMANN, Prof. E., and G. C. SCHMIDT:
Discharge Phenomena in Rarefied Metallic Vapours, 851
Wiring *624*, (*Bergmann Conduit*) 781, (*Concentric and Interior Conduit*) *141*, [Mavor] 161, [Bathurst] 190, (*Discussion at Institution*) 448, 554, 626, (*Fotheryill Prize*) 811, (*German Rules*) 408, (*Insulation Curves*) 386, (*Overseas House-wiring*) *433*, ("*Safety*" *Concentric*) 340, (*St. Pancras Rules*) 677, 700
Wire-cabling and Serving Machine, 594

Z

ZACHARIAS, F.:
Advances in the Theory and Construction of Secondary Batteries, 818

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861—1878.

No. 911. [Vol. XXXVI. No. 1.] FRIDAY, NOVEMBER 1, 1895. PRICE SIXPENCE.

NOTES.

In our issue of July 5th our New York correspondent called attention to a novel electric tramway system, which had recently been developed by the Westinghouse Electric Company. It seems that for some considerable time Mr. GEORGE WESTINGHOUSE, jun., has been experimenting with a view to the perfecting of an electromagnetic underground system of electric traction. At a critical moment, however, it was discovered that the essential features of his invention had already been patented by Mr. JEROME WHELESS, and were being worked by the Electromagnetic Traction Company on an experimental line in Washington. Promptly the Westinghouse Company acquired the patent rights to this invention, and the system is now being introduced by them into this country. Last week we had an opportunity of inspecting a small model of the type of road track and car which it is proposed to adopt. The perfect working of a model is very little guide, even to the mechanical suitability of any new system of traction, and it can form no indication whatever as to its financial qualifications. Unfortunately, the exact cost of this system, per mile of track, does not appear to be forthcoming just yet; and all we have been able to learn is that it is cheaper than the slotted conduit system but dearer than the overhead trolley—a very wide range indeed. Be that as it may, we shall await with interest the development of this system on a commercial scale; for it is one which, for all its possible drawbacks, possesses advantages. In the Westinghouse system all that is visible to the naked eye is a double row of iron contact plugs, lying nearly flush with the track and spaced in pairs at about 20ft. apart, together with the covers of an equal number of road boxes containing the electromagnetic device for connecting the contact-plugs to the feeders whenever a car passes over them. The electromagnetic device is worked by a couple of small storage cells carried by the car, the current from which passes through the pair of contact-plugs and a local relay circuit. We hope shortly to give a detailed description of the electromagnetic switch employed.

At the meeting of the Institution of Mechanical Engineers last Thursday week, the Lille experiments upon the comparative efficiency of ropes and belts for the transmission of power —from which we expected so much, and got so little—were the subject for discussion. The unanimous opinion of the speakers seemed to be in accord with our own opinion, expressed in our leading article on these experiments, in our issue of May 3, 1895. At that time we pointed out that the results of these trials of ropes and belts threw no useful light on any one of the questions which pressed for answer, in regard to the economical use of these methods of power transmission. All the speakers who took part in the discussion last Thursday week seemed to regard the Lille undertaking as a good opportunity for useful work thrown away. It appears to have been marred by two principal defects: a deadening formalism, which led the commission to draw up rigid resolutions and blindly to adhere to them, to say nothing about the nonsense of striking a medal; and a want of apprehension of the practical matters requiring investigation. Indirectly, however, these experiments have proved useful; for they have led to a very practical discussion of the subject by the Institution, in which competent authorities said useful things; and we hope they have also stirred up engineers to recognise the need for a thorough investigation, and that someone will take up the matter and carry it to a final solution.

MR. CROMPTON was disposed to regard the matter as being of less importance now than it was a few years ago. The time was at hand when ropes, belts and shafts would gradually vanish before the conquering electromotor; and makers of pulleys were promised a bad time in the near future. He, however, favoured an inquiry into the matter of the efficiency of rope and belt gear; and took the view that one of the most accurate methods of experiment was to employ two similar dynamos geared togther, the one running as a motor driving the other. If the internal efficiencies of these machines have previously been obtained by the two-dynamo method; and if the in-put and out-put of electrical power be measured, when they are running geared, the mechanical power wasted in the gear is quite easy of calculation from the data thus afforded.

TAKING indicator diagrams for the purpose of discovering whether the ropes or the belt consumed the greater amount of power seemed to Mr. MICHAEL LONGRIDGE very much like putting a hazel nut and then a walnut under a steam hammer, and comparing indicator cards to find out which nut is the harder to crack. The placid conclusion of the Lille committee that there is really not much difference between the efficiency of rope and of belt gear is, it would appear, due

Digitized by Google

to the whole of the difference between them being swallowed up by the errors of observation, owing to the very roundabout method chosen and the large magnitude of the quantities directly measured.

Interest in the use of three-phase transmission for electric traction has been augmented, in this country, since it was decided to adopt it for the Dublin electric tramways. This will be the first application of that particular system in the United Kingdom; but two examples have already been in existence for some time in the United States, and a third has recently been put into operation. The first case of this kind is to be found at Norwich, Connecticut, where three-phase current is transmitted a distance of 4½ miles, and a synchronous motor drives the continuous-current generators through countershaft and belts. The next instance is to be found at Sacramento, in California, the continuous current for the 500-volt trolley circuits in that place being generated by three-phase current supplied at 11,000 volts, the power being transmitted at this pressure from a water-power station 24 miles from the railway generator house. In this case, also, belt gear is used for coupling the polyphase motor to the continuous-current generators.

The latest example of American practice in this respect, however, at Lowell, Mass., shows considerable improvement upon the two earlier ones. The obvious advantage of combining polyphase motor and continuous-current generator in one machine has been recognised and utilised. The three-phase current is there generated at 360 volts; and is then transformed up to 5,500 volts, at which pressure it is transmitted partly to the further end of the railway, and partly to a point about mid-way between its termini. The length of railway served is 15 miles. At the two points fed the pressure is first reduced from 5,500 volts to 360 volts, and the three-phase current is then transformed into a continuous 500-volt current. We understand that the system has proved a great success, and has already enabled the railway to grapple with a very large traffic.

The daily Press is admittedly an important, nay, an almost indispensable factor of modern civilisation, but there is room for improvement, and in no direction is this more conspicuous than in the columns dealing with scientific and engineering matters, which are too often treated in the same slipshod and sensational style as the latest "horror." A good instance of this penny-a-liner method is the following paragraph clipped from a recent issue of the *Manchester Evening News*. London oculists, we are told, are in a state of very undignified agitation; they are "up in arms against the very serious danger to the community caused by the electric light. Dr. Critchett, Dr. Nettleship, and other eminent eye-doctors are agreed on the point that unless a stop is put to the exposure of uncovered electric lights in the streets and in shops and offices, we shall all become blind, or nearly so. The mischief is not so much in frosted glass globes as in the plain glass ones, which expose the dazzling wires. These lights have the same effect upon the eye as gazing at the sun. Experts think so strongly in the matter that they even suggest that Parliament should take it up, and prohibit the use of plain-glass globes for electric light unless they be properly shaded. The case, however, hardly seems one for compulsory measures. The warning given by the oculists should have the effect of inducing more thoughtfulness on the part of the public."

Not even the most enthusiastic electrician would, we suppose, suggest that naked arcs and incandescent filaments were objects to be gazed at without limit. But naked arc lights are not usually placed so as to come within the line of sight, and when they do so accidentally, whatever may result, the injury to the eye is quite negligible. The filament of a glow lamp is, on the other hand, more likely to meet the eye, but a frosted bulb is an extremely simple and most absurdly common way of entirely getting over that difficulty, and whatever the discomfort—and it is not small—which the absence of frosted bulbs may cause to those with weak eyes, the actual permanent injury to the eye by the glowing filament is no greater that than due to an ordinary gas flame. These pseudo-scientific paragraphs would, however, we expect, be left unread unless their writers liberally salted them with exaggeration and discovered certain blindness in glow-lamp filaments and serious public dangers in everything.

Owing to pressure on our space we have been compelled to hold over some of our correspondence until next week.

International Science.—The Paris Municipality agreed on Monday to erect a statue of Sir Isaac Newton. A street in Paris already bears his name.

Cable Interruptions and Repairs:—

	Date of Interruption.
Cadiz-Teneriffe	Sept. 25, 1895.
Maranharn-Para	Oct. 10, 1895.
Bonny Cameroons	Oct. 30, 1895.

Amazon Cable.—The survey of the route for the Amazon cable, and the landing places and sites for 14 stations have been settled upon. The gentlemen who have been engaged on this work are now *en route* for London.

The Arc Light.—Prof. Silvanus Thompson's Cantor Lectures on this subject, delivered in January last, are now being published in the *Journal* of the Society of Arts, Lecture I. appearing in the issue of October 25th.

General Electric Company of America.—It is stated by American technical journals that in 1886, when the Edison works moved from New York to Schenectady, 400 men constituted the working force, and they found quarters in three moderate-sized buildings. To-day 4,500 men are employed by the General Electric Company. They occupy 65 buildings, utilising 40 acres of ground.

University College, London.—Evening classes for advanced lectures and laboratory work will be opened early in November. The departments open will be Applied Mathematics, Mechanical Engineering, Electrical Engineering and Chemistry. Students wishing to enter should communicate by letter with the professor of the subject they propose to take up. The work is being carried out at the wish of the Technical Education Board of the London County Council.

Obituary.—The death, on Friday last, is announced of Dr. Julius Maier. Dr. Maier was born in Stuttgart, and was educated there and at Göttingen University. He came to England in 1866, and was science master at Cheltenham College from 1872 to 1883. He was author, joint author or translator of several electrical books, the most noteworthy being the

Digitized by Google

one on "The Telephone and its Practical Applications," published in November, 1888, in which he collaborated with Mr. Preece. Dr. Maier's death took place at West Kensington; he was 55 years of age.

A Proposed New Madagascar Cable.—A committee has been holding meetings at the Ministry of Posts and Telegraphs to study the question of laying a submarine cable between Tamatave, Reunion and Mauritius. The estimated cost is from £100,000 to £140,000. If this scheme is carried out Madagascar will possess a double connection with the general cable network of the world.

Trinidad.—It is reported that a satisfactory agreement has been arrived at by the Government with Brazil in regard to the small island of Trinidad, off the Brazilian coast, upon which a naval party was landed to ascertain its suitability as a station for the new South American cable. It is understood that the title to the island is no longer in dispute, and that the incident may be regarded as closed.

Fires of Electrical Origin in America.—In a Paper read before the Fire Underwriters' Association of the North-West, Chicago, Mr. W. H. Merrill stated that a comparison of causes among 815 electrical fires published in the first eight reports shows that 113, or over one-seventh, of these losses were caused by the crossing of telephone, telegraph and similar wires with trolley or electric light wires. Heavy current flows established by such accidents through telephones, telegraph instruments and switchboards always result in damage to these devices, and oftentimes in their destruction, and the communication of fire from them to surrounding combustible material. The total loss due to these 113 fires was $324,957.50 (about £65,000), which is a pretty large sum to charge to accidents which must be considered preventable.

Flywheel Accident.—"The bursting of a flywheel and partial wreck of the Hudson Electric Light Company's station at Hoboken, N.J.," says the *Electrical Engineer* of New York, "points a lesson which may well be impressed upon those in charge of central stations. It seems that a short-circuit on the line had blown the fuses, and during their replacement the engineer had slowed down the speed of the engine *by raising and holding up the governor*. The new fuses had no sooner been replaced, however, when they blew again, and the engineer becoming 'rattled,' in order to slow the engine down again, held the governor *down*. The result was natural, and the engine raced until the flywheel burst. The unfortunate engineer paid with his life the penalty of his carelessness. But it seems hardly credible that anyone should take such a means of reducing an engine's speed, instead of shutting off the steam at the valve."

Dirty Lamp Posts.—Commenting on the dirtiness and unsightliness of many street lamps, the *Journal of Gas Lighting* says that it "is greatly to be wished that the authorities who are responsible for giving and maintaining an air of smartness in the streets, would look more keenly into this matter of the lamp-posts, and remove the old stagers which, although aged, are not in the smallest degree venerable or picturesque in their decrepitude. And when they do set up new and acceptable lamp-posts, it could be desired that they should show more solicitude about keeping them clean. A dingy or smeary lantern is a great reproach to whoever may be responsible for its condition; and cracked and broken glass is the abomination of desolation. But, in England, lamp-posts, railings, guard-posts, and all the miscellaneous appurtenances of a modern thoroughfare, usually exhibit an innocence of soap and water that is anything but creditable to us as a cleanly people."

The Pacific Cable Scheme.—Reuter's Agency states that, at the invitation of Sir Charles Tupper, a meeting was held at the office of the High Commissioner for Canada on Tuesday morning to discuss the Pacific cable scheme. In addition to the High Commissioner for Canada, there were present the representatives of the Australasian and South African Colonies. The instructions sent by the various Colonial Governments to their representatives were discussed, in view of the probable forthcoming conference with the Secretary of State. Reuter's Agency is informed that the Colonies, being quite prepared substantially to support the scheme, are desirous that the question should no longer remain in abeyance. It is added that the reported granting of a concession for an exclusive American cable between the United States and the Hawaiian group will probably necessitate the landing of the British cable on another Pacific island at a higher cost. The date of the conference with Mr. Chamberlain will not be fixed until the return to town of the Secretary of State.

Electric Locomotives for the Huron Tunnel.—It is stated, says the *Electrical World* of New York, that the management of the Grand Trunk Railway is contemplating the adoption of electric locomotives to haul its passenger trains through the tunnel under the Detroit river at Port Huron, the locomotives to be similar to those in the Baltimore and Ohio tunnel under Baltimore. "A desire to avoid smoke and cinders was amongst the causes which induced the Baltimore and Ohio Company to instal electricity. The Grand Trunk is forced to abandon steam engines, so it is said, because of their effect upon the tunnel structure. The latter, cut through the rock, is lined with steel casing, at the back of which is a filling of what is said to be a peculiar kind of asphalte. The tunnel is 1⅛ mile in length, and the gradient at both ends is 105 feet in the mile. Specially constructed locomotives, weighing 95 tons and having eight drivers, were used to haul the train through. In developing energy enough to haul long heavy trains it has been found, it is stated, that the excessive heat and escaping steam from the engines is exercising a deteriorating effect upon the asphalte backing, and it is stated that steam has been found to exercise a serious influence upon the other portions of the tunnel structure."

Efficiency of a Generating Plant.—At the fifth convention of the Canadian Electrical Association at Ottawa, on September 17th, Mr. James Milne read a Paper entitled "From Coal Pile to the Meter." The author presented an interesting series of curves, calculated from different sources, showing the efficiency of the various parts of a generating plant. These results, expressed in percentages, are given in the table below :—

Power for running generators	100
Power available at switchboard	92
Power available at meter	78·20

Efficiency of the electrical apparatus, including outside circuit = 78½ per cent.

Engine	100
Available for generating current	83·3
Available at switchboard	75·72
Available at meter	64·35

The commercial efficiency from engine to meter is 64·35 per cent.

Boiler equivalent	100
Indicated H.P. at engines	7·04
Available for generating current	5·79
Available at switchboard	5·33
Available at meters	4·53

The efficiency therefore from the boilers to the meter is 4·53 per cent.

Coal pile equivalent	100
Available at stop valves of boiler	62·47
Indicated H.P. at engine	4·4
Available for generating current	3·62
Available at switchboard	3·33
Available at meter	2·83

The Action of Flywheels.—An interesting experiment is described in *Electric Power* of New York, relating to the endeavour to secure the more uniform running of a dynamo driven by a gas engine. The first proceeding was to determine the amplitude of the angular displacement of the flywheel relative to the normal position it should occupy if speed were invariable. The flywheel was illuminated by means of a Geissler tube, excited by a Rhumkorff coil, regulated so that its flashes coincided with the frequency of the passage of the flywheel arms through a given position. So long as the flywheel velocity was constant, the arms were visible at this instantaneous position by the light of the flashes, and the wheel appeared to be stationary; but when the velocity varied and the wheel ran slower it appeared to have a slow retrograde movement, for the arms did not reach the given position at the moment of flash. Then, a fresh explosion taking place, the wheel would appear to slowly reverse its movement and over-

Digitized by Google

run the flash point. In fact, the wheel appeared to swing slowly between two extreme positions, and its angular movement was easily measurable, the eye grasping readily the progress of the alternate advances and retrogressions. In light running, with one explosion every four or five cycles, the maximum angular movement was 50deg. With load on, and only one explosion missed out of four or five possible, the angularity was 8deg. for successive explosion cycles, and attained barely 12deg. after a non-explosive cycle followed by explosion.

Lightning Arresters for Light and Power Circuits.—In its issue of October 17th the *Elektrotechnische Zeitschrift* discusses the above-named subject. The gist of its remarks are as follows:—It is about 50 years since electrical engineers recognised the necessity of protecting electrical circuits by lightning arresters, and during that time the apparatus constructed for this purpose has generally proved quite satisfactory for telegraphic and telephonic circuits. The same, however, cannot be said of the apparatus intended for the protection of light and power circuits and electrical machinery. It may seem strange at first, that a contrivance which is reliable enough to protect the most sensitive receiver of a transatlantic cable cannot be employed for the protection of far more robust objects, such as dynamos or transformers. There is, however, a difference in principle. While in the first instance it is sufficient to keep the discharge from the instruments, in the second the instrument is required, in addition, to prevent the working current from following the path created for it by the lightning discharge. It is especially this latter condition which makes the problem so difficult, and which has resulted in a great number of ingenious contrivances. The practical value of these are regarded differently, and though the *Elektrotechnische Zeitschrift* would not like to say that the various lightning arresters at present in the market are not the best which can be made under existing circumstances, it would like to point out that even these do not afford that degree of safety which could be wished for in the interest of the industry. The main reason for this uncertainty, in which we still remain in regard to the best types of lightning arresters, is that we are still unable to produce artificial lightning which would allow of a systematic testing of apparatus. So far, laboratory experiments give us only an approximate verdict on the value of this or that type, and the real test must be left to nature and chance. In this way, of course, much data may be got together in time, and would allow of the design of lightning arresters on scientific principles. Up to the present, however, this point has not been reached, and an attempt to treat this question systematically and on the basis of experiment would be of great advantage to electrical engineering. Such an attempt could be made through the combined action of the different electrical societies of Germany. The experience gained with the existing type of apparatus should be first collected, and then, together with all other material, put into the hands of a committee for further investigation. The *Elektrotechnische Zeitschrift* proposes to further discuss the subject in its columns, and invites correspondence.

Silverton (Col.) Three-Phase Transmission Plant.—An interesting application of the three-phase system of transmission of power has recently been carried out at the Silver Lake Mines, near Silverton, Col., where power is transmitted a distance of three miles through some of the roughest country in Colorado. It is attracting considerable attention among mining men, as it is the first three-phase plant installed in the Rocky Mountain region. The Silver Lake group of mines, says the *Electrical Engineer* of New York, lie about four miles south-east of Silverton, and are situated at an altitude of 12,300ft. above sea level. Previous to the installation of electricity the mill, which is situated on the shores of the Lake, near the mouth of the mine tunnel, was run by steam. Coal was brought to the steam engine by a tedious path up the mountain, and by the time it reached the furnace cost $8.75 a ton. The plant is now operated by water power, which is brought from the Animas River, above Silverton, through a 3ft. by 4ft. flume 9,750ft. in length, which carries 2,350 cubic feet of water per minute. One of the great advantages of electrical utilisation is here demonstrated, for it was found less expensive to build this costly two-mile flume, running from above Silverton down to a spot where the necessary head could be utilised, and then to transmit the electricity back to the mine, rather than to continue to burn coal at the price which it brought at the mouth of the Silver Lake mines. The head of water obtained is about 180ft., which develops on the water-wheel shaft 640 H P. The plant consists of two 4ft. double-nozzle Pelton water wheels, with special buckets belt-connected to two 150 kilowatt General Electric three-phase generators. The current from these machines is delivered at 2,500 volts, and is transmitted over a distance a little more than three miles to the Silver Lake mill and mine. The conductors are bare copper wires, one for each branch of the three-phase circuits. These are strung from the power house, up the mountain passes, and through the rugged country. In one place where a chasm has to be spanned the wires are strung on poles 275ft. apart. At each insulator the wire is run through a short piece of rubber tube as an extra precaution against leakage. Lightning arresters are placed at each end of the line, and an additional safeguard against damage by lightning is provided in the shape of a barbed iron wire, which extends the entire distance of the line along the tops of the poles, and is grounded at every second pole. Arriving at the mine, the current is supplied to a 100 H.P. three-phase induction motor run directly from the primary circuit. Another 100 H.P. motor, as well as one of 75 H.P., are located beneath the ground, and current is supplied to these at a pressure of 220 volts, the reduction in pressure being effected by step-down transformers. In addition, a 15 H.P. motor runs a pump raising water from the Lake to the mill, and one small 1 H.P. motor operates a blower and the lights for a bunk, office and other buildings, both being connected to the secondaries.

Current Electrical Science.—Prof. Cardani, of Parma University, contributes an important Paper to the *Nuovo Cimento* dealing with the RESISTANCE OF CIRCUITS TO ALTERNATING CURRENTS. The work begun by Dr. Lodge and Lord Kelvin is carefully elaborated, and the results appear to admit of no doubt. Resistances were measured by the heating effects, as was done by Ignaz Klemencic (see *The Electrician*, October 18th, p. 812). The wires were surrounded by a tube containing petroleum, and communicating with a capillary "thermometer tube." The heat developed in the wire expanded the petroleum, and the rise of the petroleum in the capillary tube indicated the amount of heat and the temperature. An influence machine was discharged through a divided circuit, consisting of two such wires with thermometers. In this manner various wires were tested for resistance to alternating discharges. The law of diameters seems to be a very complicated one. For copper and brass there was a certain diameter, for which the resistance was a maximum. Platinum is the best conductor at larger diameters, but when it becomes very thin the resistance increases enormously. As regards the vexed question of the comparative resistances of iron and copper, Prof. Cardani finds that at larger diameters they are equal, but that thin iron has a lesser resistance than thin copper. Another Paper of some interest is one by A. Garbasso, on the double refraction of RAYS OF ELECTRIC FORCE. This was observed with Righi's tinfoil strip apparatus. Double refraction effects were obtained with calcite, Iceland spar, felspar and mica.—In the *Journal de Physique* for October, MM. Abraham and Lemoine describe an attracted disc electrometer for VERY HIGH POTENTIALS, say 100,000 volts. The commercial type is constructed on the principle of Roberval's balance, and is claimed to measure within 1 per cent. A curious feature about this instrument is the primitive manner in which the guard ring is brought into position, viz., by bending the S-shaped soft-copper wires by which it is suspended. Accurate results are obtained so long as the distance between the plates does not exceed half the width of the guard ring. *Apropos* of Cardani's assertion that the resistance of some wires increases with their diameter, we have in the *Journal de Physique* the equally startling announcement that the resistance of a spark is greater the smaller the gap. This is explained on the hypothesis of a counter E.M.F. due to a detaching of particles by the short violet sparks. The strong white sparks offer less resistance. If anybody doubts this let him try the experiment.

MOTIVE POWER AND GEARING.*

(*Continued from page 822, Vol. XXXV.*)

BY E. TREMLETT CARTER.

The Otto Cycle.

Historical Summary.—The invention of the gas engine was made when it was first perceived that the power of explosives, such as gunpowder, to move things might be applied to make them move machinery, and when this power was first thus applied. To the Abbé Hautefeuille, pious and worthy son of an Orleans baker, is due the credit for having invented the earliest recorded gas engine, on these lines; for it was in the year 1678 that he devised a pump by which water was raised by the expansive energy of ignited gunpowder. Passing over the long series of inventions of the gunpowder type, however, we find that in 1791 the first engine in which gas, admitted as such into the engine, acted explosively was invented by one John Barber. The gaseous fuel was obtained by the distillation of wood, oil, coal and other hydrocarbon producing substances. A great advance was made in 1801 by Lebon, a French engineer, who conceived the idea of compressing the gas and air in two separate cylinders before admitting them to the explosion cylinder. It was not until 1833 that the gas engine was fitted with a governor to control its speed, this improvement having at that date been introduced by Wright. The governor, in this case, was caused to control the richness as well as the quantity of the explosive charge admitted to the cylinder. Wright's engine also had the improvement of a water jacket for keeping the cylinder cool. Some five or six years later, an Englishman, one William Barnett, who had already devised two types of gas engine, now developed a third invention, which anticipated in a remarkable degree many of the features of the modern gas engine. Like all of the early engines, his was double-acting; but its most important feature was the realisation of Lebon's scheme, of a separate compression pump for the gas and air. Another interesting feature was the ignition of the gas at the dead point, previous engines having been devised to explode the charges nearer the middle of the forward stroke. In 1860 a type of engine which, at a later date, became considerably developed, was introduced by two Italian engineers, Barsanti and Matteucci. Their engine was designed to cause the explosive force to act upon a piston momentarily free and disconnected from the crank shaft. The cylinder was vertical, and the explosion lifted the cylinder to such a height as to produce a very high ratio of expansion of the gas. In this high expansion lay the extraordinary merit of the engine. When at its highest point, the heavy piston was geared to the crank shaft, and, in its down stroke, caused this to revolve. Both the weight of the piston and the atmospheric pressure acted to drive the crank during the working stroke.

None of these engines, nor of any up to this date (1860), had been commercially successful motors; and, of those few which were actually made, a very small proportion were capable of running for any great length of time. They were none of them practical engines. At this date, however, Lenoir patented his earliest gas engine, which, gradually improved as time went on, but substantially unaltered, was the first type of commercial engine driven by the explosion of admixed gas and air in a cylinder. A great number of the Lenoir engines were rapidly put to work in this country and in France; and these remained in action until a better class of gas engine was able to replace them, many of them lasting for a great number of years. The Lenoir engine was double-acting, horizontal, and designed to admit the gas and air and to exhaust the waste gases by means of two slides, which were driven by eccentrics on the crank shaft. Ignition was by electric spark; and all parts of the cylinder were water-jacketed. During the early part of each stroke the explosive mixture was drawn in; and at half stroke or a little later this was fired, the explosive force acting throughout the remainder of the stroke.

* From a forthcoming work to be published by *The Electrician* Printing and Publishing Company. All rights are reserved.

Stratification.—An erroneous notion, which it is important to notice, was very prevalent at this time, and throughout a much later period, relative to the arrangement of the various gases in the cylinder during the in-draught stroke. It was supposed that the several portions of gas, air and residual products of combustion arranged themselves in strata; and valves were designed to have the supposed effect of stratifying the gases as follows: (1) next to the piston was to be a layer of products of combustion; (2) behind this was to come a layer of mixed explosive gas; (3) still further back it was sought to have a stratum of gas alone; and (4) at the very back of the cylinder there was to be only air. It was believed that the strata of incombustible gases acted as cushions, to mollify the shock of the explosion on the piston and cylinder end. It is remarkable to what a very late date this doctrine was preached, even from engineering chairs in our colleges. Yet, when we think in how short a time an escape of gas at one end of a large room can be detected by a nose at the other end; or when we remember that the entry into a large apartment of a person smoking tobacco soon causes the entire room to be filled with the odour of the weed; we find it impossible to believe that a rapidly moving piston does not produce sufficient commotion among the gases which it draws into the cylinder to utterly destroy any want of homogeneity and completely obliterate every trace of stratification. It seems most probable that at the moment of explosion the whole of the space behind the piston is filled with a gas of uniform composition.

Beau de Rochas.—The Lenoir engine and the host of imitations of it having been placed upon the market, and having worked on a commercial basis for some two years or so, facts and data were becoming available for a systematic study—in the light of the science of that day—of the causes of inefficiency, and of the conditions which might be expected to lead to greater economy in working. Had the inventors themselves possessed that degree of scientific knowledge which was requisite for such a study they themselves might have discovered and have applied to their engines the great and far-reaching principles which were being worked out by Beau de Rochas, in France. But empiricism had entirely guided these inventors; and it was not until Beau de Rochas published his patent specification, in which—not an engine—but a great general mode of working was specified, that the gas engine was placed upon a sound, economical basis of construction. *Verbum sat sapienti.*

Beau de Rochas published his conclusions in 1862. They specified that the four essential conditions of high efficiency in a gas engine were:—

(1). That the ratio of the cylinder volume to the surface of cylinder and ends should be as large as possible.

(2). That the piston speed should be as high as possible.

(3). That the exploded gases should be expanded to as large a volume as possible.

(4). That the initial pressure of the gases at the moment of explosion, or commencement of expansion, should be as high as possible.

In projecting an engine wherein these conditions might be fulfilled, Beau de Rochas laid the foundation of the modern type of gas engine; and by embodying this project in his patent he foreshadowed the greatest, if not the only, master patent which the history of the gas engine has known. This project, indeed, was no other than the so-called "Otto" cycle of operations of the gas engine; and though it was drawn out in every detail by de Rochas, it was reserved to Otto to construct the first engine actually working upon this system. Hence the term "Otto cycle."

The Otto Cycle.—What Beau de Rochas proposed and what Otto, but not until 1876, actually accomplished, was the construction of a gas engine working with the following cycle or rotation of operations, each operation occupying the period of one complete stroke of the piston:—

1st Stroke.—Charging stroke: in-draught of gas and air in explosive proportions.

Digitized by Google

2nd Stroke.—Compression stroke: compression of the explosive charge into the small volume of the clearance behind the piston.

3rd Stroke.—Working stroke: ignition of the explosive charge at or near the dead point and expansion of the fired charge.

4th Stroke.—Exhaust stroke: rejection of the products of combustion from the cylinder.

It must be carefully borne in mind that the above is a specification of a system of working rather than of a definite engine. Various kinds of gas engines work on the Otto cycle. When this cycle takes place at only one end of the cylinder, there will be one explosion and one working stroke every two revolutions of the crank shaft; unless, indeed, as is often the case, there are two or more cylinders actuating the same shaft. In some engines both sides of the piston are acted upon, an Otto cycle occurring at each end of the cylinder: in such cases there will be an average of one working stroke per revolution.

Otto's Engine.—Continuing our historical summary, we may pass over the years intervening between the date of Beau de Rochas's publication (1862) and 1876, the date when the first engine constructed to work upon the de Rochas (or Otto) cycle was patented. The honour of the invention and making of this first of the modern type of engine is due to the celebrated German engineer whose name is now universally identified with the cycle of operations described in the preceding paragraph. The essential characteristic of Otto's gas engine was that all four of the operations were arranged to take place in the same cylinder, the gas being compressed after admission, as advocated by de Rochas. The engine was single-acting, the non-working end of the cylinder being open. The operations took place substantially as they do to this day—that is to say, the first out-stroke drew the gas and air into the cylinder, the first in-stroke compressed the mixed gas and air into a capacious clearance space behind the piston, ignition now took place, and the second out-stroke occurred under the impulse of the fired gases, while the second in-stroke cleared out the greater part of the waste gaseous products of combustion. The gas and air admission, and the firing of the charge were controlled by a slide valve placed at the working end of the cylinder; and the exhaust was effected by a "mushroom" valve, which was opened by a cam and closed by the action of a strong coil spring. Firing was effected by a gas flame carried in a pocket or chamber in the inner side of the slide valve.

Thermodynamics of the Otto Cycle.—We may now discuss some of the more important properties of the working substance in a gas engine which follows the Otto, or any practically similar cycle. It must first of all be pointed out that the Otto cycle is not a cycle of operations of the working substance, but of the engine; it is in no sense analogous to Carnot's cycle. The gas itself undergoes no complete cycle, and it is rejected irrecoverably at the exhaust. The most important questions relate to the highest temperature attainable during the working stroke, and the lowest possible on exhaust. Upon these the limiting efficiency of the Otto cycle must depend. Robinson has calculated that if all the heat of combustion could be liberated in the moment of explosion, and before any useful work could be done, or any heat be lost, a temperature of about 3,900°C. would be attained, the mixture consisting of 5·76 cubic ft. of air for each cubic foot of coal gas. On the other hand, we have the evidence as to dissociation, first educed by St. Claire Deville, that chemical union between two gases cannot take place above a certain temperature, the magnitude of which depends on the nature of the gases. With oxygen and hydrogen the dissociation temperature is said to be about 1,200°C. (2,192°F.), in which case the limiting temperature of the gas in an engine cannot exceed this figure. If, for argument's sake, we take 2,000°F. as the highest theoretically possible temperature, and—since the exhaust is at atmospheric pressure—212°F. as the lowest possible exhaust temperature, we shall find that the theoretical limiting efficiency is as high as 72 per cent!

Conditions which Reduce the Efficiency.—By comparison with the theoretically highest efficiency of a steam engine, that of a gas engine is an extraordinarily high figure; the cause lying in the enormously greater temperature attained by the working substance. But, just as the steam engine never attains its highest efficiency, so there are conditions of action in the gas engine which, either by necessity or by imperfection of construction, involve greater losses than the foregoing calculation specifies. We will now briefly enumerate these:—

(1) *Structural Conditions.*—The development of a temperature approximating to 2,000°F. in a metal cylinder provided with a reciprocating closely-fitting piston is, with the materials at present available, a structural impossibility. Gas at so high a temperature remaining long in contact with the parts of the engine would speedily raise them to red or even white heat. Moreover, not only is the topmost temperature limited, but that highest temperature which is permissible cannot be allowed to last very long. Heat must continually be abstracted from the gas, during the whole of the working stroke, in order that the cylinder walls and piston may not become over-heated. Thus, heat is being rejected from the working substance at temperatures far exceeding that of the exhaust; and, in actual practice, the greater part of the total heat has to be abstracted in this way.

(2) *Chemical Conditions.*—It is chemically impossible for the whole of the charge to be fired instantaneously at the beginning of the working stroke. The chemical combination between the gas and oxygen is of necessity gradual; and, in practice, it lasts throughout the working stroke. As a consequence, only a portion of the heat is liberated at the highest attained temperature, a considerable other portion being developed at a gradually lowering temperature. There are practical reasons why this condition is preferable to the development of all the heat instantaneously at the topmost temperature, even if this latter were possible.

(3) *Thermodynamic Conditions.*—Apart from the need for wasting heat in order to keep the engine workable, an unnecessary amount of heat is wasted by the rejection of the exhaust gases at too high a temperature. The direct cause of this is the insufficient expansion which the exploded gases receive before release.

(4) *Mechanical Conditions.*—The mechanical imperfections of the gas engine, working under the Otto cycle, comprise limitations of piston speed, whereby the hot gases are detained in the cylinder; and the limitation of the working stroke to one one-fourth of the motion of the engine, whereby the engine has to turn itself against its internal friction for three idle strokes to every active one.

Where the Heat Goes.—We are now in a position to track down the various portions of the total heat developed, to see where they are wasted and where used, and to consider in what ways the wastes may be minimised. The channels of outlet for the heat are:—

I. Indicated work, comprising internal work done mechanically and external work.

II. Exhaust heat.

III. Water jacket heat, or heat abstracted through the cylinder walls, in order to keep the engine cool.

IV. Ignition gas heat, or the heat which is used in maintaining an ignition flame.

V. Incomplete combustion of the gaseous fuel.

Indicated Efficiency.—Actual tests show that the indicated efficiency of gas engines depends upon their size and rated power. Working at its most economical load, a gas engine has a higher economy, up to a certain point, the larger is its size and rated power. For moderate sizes, the consumption of average town gas, at the best load, will be about 20 to 25 cubic ft. per I.H.P. per hour; and in very large and well-attended engines it may fall to 15 cubic ft. per I.H.P. per hour. Very small engines in general work often consume from 25 to 30 cubic ft. per I.H.P. per hour at their rated loads. The 2-cylinder tandem "Otto" gas engines, by Messrs. Dick, Kerr and Co., built for the Belfast gas engine electric supply station, and rated at 120 I.H.P., were guaranteed to consume not more than 26 cubic ft. of gas per electrical horse-power, and were found on trial to consume

Digitized by Google

24 cubic ft. per electrical horse-power at full load. The combined efficiency of the engine and dynamo being 76 per cent. (by actual tests made at Kilmarnock), it follows that the consumption of gas was about 18·24 cubic ft. per indicated horse-power per hour; while the guarantee was equivalent to 19·76 cubic ft. per indicated horse-power per hour. Again, in a large number of gas engines at Messrs. Crossley's works, having an aggregate of 250 H.P. to 350 H.P., the consumption of anthracite (for Dowson gas) was about 1lb. per indicated horse-power per hour, the load varying according to the requirements at the works. This represents a dynamical efficiency of about 18 per cent. The following Table gives further evidence on this question:—

Table XXXI.—*Efficiency and Economy of Gas Engines working on the "Otto" Cycle.*

Gas engine.	Date of test.	Authority or experimenter.	Duration of test.	I.H.P.	$\eta = \frac{\text{B.H.P.}}{\text{I.H.P.}}$	B.T.U. per I.H.P. per hour.	Cub. ft. gas per I.H.P. per hour.
Otto-Crossley.	1881	Adams	...	33·6	0·82	16,000	23·6
Ditto ...	1888	Soc. of Arts	6 hrs.	17·12	0·86	12,120	20·76
Ditto	1892	Capper	2 hrs.	13·32	0·85	...	20·87
Simplex .:.	1885	Witz	2 hrs.	9·10	...	13,338 per B.H.P.	20·38 per B.H.P.
American "Otto.".	1893	Sprangler	3 days	127·6	0·72	...	0·95lb. solid fuel for Dowson gas.

Brake Efficiency.—The foregoing Table shows the ratio of the brake horse-power to the indicated horse-power in a number of "Otto" gas engines; and it may now be generally stated that for engines of large or moderate powers, the ratio varies from 80 to 85 per cent. at full load. With small gas engines it is often very much lower than this, causing the gas consumption per horse-power to rise to high figures. Taking an average of 82 per cent., and estimating the average consumption of gas at 20 cubic ft. per indicated horse-power per hour, the gas having a thermal value of 740 B.T.U. per cubic foot, we find that the proportion of the total heat developed which is utilised in external work is about 14·5 per cent. And according to the same data, the heat wasted in internal (engine) friction is about 2·61 per cent. of the total heat developed.

Exhaust Heat.—The temperature of the products of combustion throughout the period of exhaust depends upon the following conditions: (1) the piston speed, (2) the richness of the exploded charge, (3) the amount of gas admitted in each charge, and (4) the water-jacket arrangements; as well, of course, as upon the size of the engine. It is generally found that, with an unchanged ratio of expansion, an increase in piston speed causes a rise in temperature of the exhaust gases—*more* heat is carried away by the exhaust. The reason for this is evident, since the gases, being hurried through the working stroke, have not so much time to impart their heat to the walls and the water jacket; and though a greater amount of useful work may be done, owing to the improvement in the pressure throughout the stroke, yet more heat will pass away with the waste gases. Of the heat saved from the jacket waste, some will be added to the exhaust waste. The remedy for this is to introduce a greater ratio of expansion of the gases, so that the heat may be abstracted in useful work. In ordinary practice, and with the "Otto" cycle, the temperature of the exhaust gases varies between 600°F. and 900°F., and the proportion of heat rejected in these gases averages about 16 per cent.

(To be continued.)

A Proposed Long-Distance Electric Railway in France.—It has been decided to construct an electric local railway, about 60 kilometres long, between Besançon and Levier. The line will be on the overhead-conductor system, and have a gauge of 1 metre.

ENERGY LOSS IN DIELECTRICS.*

BY P. GASNIER.

A condenser, the plates of which are subjected to a constant difference of potential, is, as soon as it is completely charged, traversed by a current which generates heat within it. The insulation resistance of condensers being, as a rule, very great, the current is small and the evolution of heat is scarcely appreciable, even when large potential differences are employed. But if we subject the same condenser to an alternating difference of potential equal in effective value to the continuous one mentioned above, the evolution of heat is far more considerable. This fact, made evident by the experiments of Siemens, and in 1891 by the experiments of Hutin and Le Blanc on a paraffined paper condenser subjected to an alternating pressure of 1,500 to 2,000 volts, shows that in this case there is added to the conductive loss a more important one, which is of a different nature. Steinmetz† was the first to measure these energy losses, taking a paraffined paper condenser of three microfarads, and found that with an alternating current of a frequency of 170 $\sim$ the loss was nearly equal to twelve times that produced by a continuous current at the same pressure. Steinmetz also found that the greater the loss due to an alternating current as compared to that due to a continuous current, increasod proportionately to the square of the pressure. He attributed this heating to a phenomenon analogous to that which takes place in magnetic metals submitted to a variable field; hence the name "dielectric hysteresis," prematurely applied to a phenomenon upon which electricians are not yet agreed, notwithstanding the large number of experiments which have been made. Pending new tests elucidating this question completely, it will be of interest to see what has already been done, and what are the conclusions which different experimenters have drawn from their work.

R. Arno,‡ who showed that a dielectric cylinder rotated in a rotary electrostatic field, applied this phenomenon to the measurement of the energy loss in dielectrics submitted to varying electrifications. The rotary electrostatic field was produced by four plates cut from a hollow cylinder and connected in pairs and subjected to two alternate potential differences having a phase difference of one-quarter of a period. The dielectric cylinder was bifilarly suspended inside and enabled the torque exerted by the field to be measured, and consequently, the angular speed of the field being known, the energy loss in the dielectric could be determined. R. Arno found the following relation between the energy loss and the strength of the field: $W = KE^{1\cdot6}$, K being a constant. Thus the exponent 1·6 discovered by Steinmetz for magnetic hysteresis turned up again. For a paraffined paper condenser Steinmetz found, however, the exponent 2.

Arno attributed, with considerable reason, the energy loss which he had discovered, to the existence of a lag of the electrification; in other words, to dielectric hysteresis. Two sorts of lag may, however, produce energy loss: either a lag in time—that is to say, a lag between the value of the electrostatic field inside the dielectric, and its value outside, or a lag analogous to that of magnetic hysteresis, where the electrostatic field, inside the dielectric, assumes values which are smaller for a rising field than for a falling field. Both these kinds of lag are shown in the magnetisation of iron. The experiments of Bour§ and of Lord Rayleigh,‖ the object of which was the determination of the value of the permeability as a function of the inducing field, showed that iron exhibits a lag with regard to magnetisation which must not be confounded with ordinary hysteresis, and which prevents the magnetic condition of the iron from following the rapid variations of the magnetising field. This phenomenon exhibits itself particularly in weak inducing fields in which the value of the permeability is constant. This phenomenon, to which Ewing gave the name of "viscous hysteresis," and which has also been called "transient hysteresis," or "progressive magnetisation," and which exhibits the general features of viscosity, gives rise to a loss of energy for a cyclically varying inducing field. The final value of the induction diminishes when the frequency of the variation of the field increases, which results in the permeability having a smaller value when it is measured with a rapidly changing field than when it is measured with a slowly changing field.

The experiments of Edwin E. Northrup¶ show the same phenomenon in the case of dielectrics. The value of specific inductive capacity is larger for a slowly-varying field than for a rapidly-

varying field, and is a function of the rapidity of the change. The following are results obtained for paraffin and glass :—

Paraffin (fusing point 54·5°C.) :—
K=2·32 for a slowly-varying field.
K=2·25 for a rapidly-varying field.
Difference=3 per cent.

Glass :—
K=6·25 for a slowly-varying field.
K=5·86 for a rapidly-varying field.
Difference=6·2 per cent.

The experiments of Blondlot and J. J. Thomson have shown even greater variations. These facts seem to show that there is a viscous dielectric hysteresis analogous to that found in iron.

The loss of energy observed by R. Arno in dielectrics may also be due to the existence of an hysteresis analogous to magnetic hysteresis, properly so-called, and which consists in the fact that for two equal values of the inducing field obtained, one when it is rising and one when it is falling, there are two different values of the induction, independent of the rapidity of the variation of the field. The method employed by Arno does not permit this question to be settled.

The experiments of Janet* on the phenomenon of mica-condenser charges when the condensers are subjected to rapid electric oscillations gave veritable hysteresis cycles with curves analogous to the well-known curves of Ewing and Warburg. Janet showed that in a condenser subjected to rapid oscillations the charges are smaller for equal potential differences when the potential is rising than they are when the potential is falling. This lag may be attributed either to hysteresis or dielectric viscosity, or to a combination of these two causes. The experiments of Janet did not enable him to be very precise on this very important point.

A. Hess,† in a memoir presented to the Société de Physique, attributed dielectric losses to heterogeneity and to the existence within the dielectric of particles which are the seat of true currents ; hence he believed there was a loss of energy totally different to that caused by the phenomenon of hysteresis. Hess likened a condenser with a heterogeneous dielectric to two condensers in series, one having an infinite resistance and the other a certain amount of resistance. Making this assumption, a mathematical investigation enables us to predict the formation of residual charges, and show that the phenomena of charge and discharge take place just as though two such condensers connected in series were replaced by a single viscous condenser. An experiment was carried out on two Carpentier condensers, one of 0·1 microfarad, and the other of 0·5 microfarad, shunted by a resistance of 100 megohms, the two condensers being connected in series. The experiment showed that in such a system the charge takes place very slowly, and that it is possible after a first and instantaneous discharge to obtain a large number of residual discharges.

Charles Borel,‡ in a Note on the dynamic phenomena due to residual electrification of dielectrics, comes to the same conclusion as Hess. Charles Borel discovered that a condenser of paraffined paper suspended at its centre by a cocoon fibre, took up a rotary movement in an alternating electric field, if a glass rod was placed on one side of the disc, the plane of the disc and the axis of the rod being parallel to the lines of force of the field. According to M. Borel this rotation is due to the phenomenon of internal and external conduction, and the heterogeneity of the dielectric plays a very important part, heterogeneous dielectrics being those which produce the strongest effect upon the disc. Charles Borel also attributes to the phenomenon of internal and external conduction the rotation of dielectric cylinders in a rotary electric field, discovered by Ricardo Arno.

The experiments of Messrs. A. W. Porter and D. K. Morris,§ on a paraffined paper condenser having a capacity of 5 microfarads, seem to dispose of the existence of a dielectric hysteresis similar to a magnetic hysteresis. A 5-minutes charge gave no trace of hysteresis. On the other hand, the same condenser presented in a very marked manner the phenomenon of viscosity. A 1-second charge exhibited, as time went on, an increase approximating 5 per cent. Messrs. Porter and Morris conclude that dielectric losses are due to these viscous effects, and not to hysteresis.

Benischke,‖ in some experiments made with a bolometer showing a difference of temperature $\frac{1}{1000}$th of a degree Centigrade, and intended to determine the rise of temperature in a paraffin plate subjected to the action of an alternate electrostatic field, failed to observe any rise of temperature, and concluded that there was no such thing as a dielectric hysteresis analogous to magnetic hysteresis. After experiments on paraffined paper, Benischke attributed the energy loss of condensers to the three following causes : losses due to the formation of residual charges (viscosity), losses due to the Joule effect, and mechanical losses due to the vibration of the sheets of the condenser.

Eisler* recently published the results of measurements made on a paraffined paper condenser having a capacity of 2·5 microfarads, subjected to an alternating current, the frequency of which was varied. The current was furnished by a Siemens 8-pole machine driven by a variable speed motor. One and the same electrometer was used to measure the effective pressure at the terminals of the condenser, the effective current and the power absorbed, which enabled the experimenter to determine the lag with great precision. Each experiment necessitated three successive measurements, and during this time the speed of the generator was kept very constant and was measured with great care. The difference of potential at the terminals of the condenser was kept constant at 34·9 volts. The frequency was varied from 17·9 to 45·1∼. Eisler's results are summed up in the following table :—

∼	Effective charging current (amperes).	Lag ϕ.	Apparent resistance of condenser (ohms).	Energy lost per cycle (ergs).
17·9	0·0084	86°21′	64,800	10,490
29·3	0·0137	85°50′	35,100	11,670
33·9	0·0153	85°56′	31,500	11,420
41·7	0·0186	85°41′	24,900	11,790
45·1	0·0198	85°28′	22,100	12,250

The apparent resistance of the fourth column is the resistance which for the same potential difference would give rise to the same loss as that produced in the condenser. The conductive loss was negligible, the condenser having an insulation resistance of 289 megohms. The last column gives the loss in ergs per cycle, and it will be observed that this loss increases as the frequency increases. Eisler thinks that this loss, which he attributes to viscosity, should attain a maximum for a certain frequency higher than that which he was able to get.

Eisler also carried out measurements with a constant frequency, varying the difference of potential at the terminals of the condenser. He found, like Steinmetz, that the loss of energy for a given frequency was proportional to the square of the potential difference. Eisler represents the loss of energy by the following equation :—

$$W = k\,C_n \times f(n) \times u^2,$$

in which k is a constant, dependent upon the dielectric, C_n the capacity of the condenser for the frequency under consideration, and $f(n)$ a function of the frequency, u the effective difference of potential, the product $C_n \times f(n)$, having a maximum for a certain value of n.

It follows from all the experiments enumerated above that the existence of dielectric hysteresis analogous to magnetic hysteresis has not up to the present been demonstrated, which leads one to the belief that it does not exist. That being so, we are confronted by two hypotheses—that of viscous hysteresis and that of internal conduction. This latter, which is very interesting, and was put forward by Hess, explains very well all the phenomena of residual charges, and furnishes a law for the variation of energy loss analogous to that found by Eisler ; it also enables us to predict the existence of a maximum energy loss at a certain frequency, pointed out also by Eisler. The influence of the existence, within a condenser subjected to variations of charge, of conducting particles cannot be doubted, and the various experimenters who have operated with impure dielectrics must have taken it into account. Nevertheless, this fact does not exclude the possibility of the existence of a viscosity analogous to that presented by iron, and new experiments are necessary on very pure dielectrics to settle the matter.

THE PORTRUSH ACCIDENT.

The following is the text of Major Cardew's Report to the Assistant-Secretary of the Railway Department of the Board of Trade, with regard to the recent fatal accident to a person named Thomas Walne, which occurred on the Portrush tramway in August last :—

Description of the Line.

The tramway upon which the accident occurred is a line 6 miles in length, constructed under powers given by the Giant's Causeway, Portrush, and Bush Valley Railway and Tramways Act, 1880, between the town of Portrush and Bushmills, along the side of the public road, and an extension which is more properly a railway, 2 miles in length, across private property, to a terminus in the immediate vicinity of the Giant's Causeway.

The line is worked chiefly by steam engines, but in addition electric motors are provided in a few of the cars, and electric power is supplied to these except for the portion of the line within the town of Portrush, where steam power is used exclusively. The electric power is supplied from a generating station at some distance from the line by means of overhead wires, the energy being obtained from water power. The charged conductor, by contact with which the electric current is transmitted to the motors on the cars, is a stiff iron rail supported at a height of about 18in. from the ground on the side of the tramrails next the hedge or boundary of the road. At road crossings and at gateways into fields, &c., the conducting rail is omitted for the requisite length, and connection effected by means of an underground cable across the break of continuity. The return circuit is provided in the usual way by means of the tramrails, copper bond wires being used to connect together the several lengths of rail. No attempt has been made to secure the public using the road or cattle driven along it from contact with the charged conductor rail.

Summary of Evidence.

The evidence submitted on behalf of the ratepayers was chiefly directed to the support of their contention that the charged rail in its present condition constituted a danger to horses and cattle, and an annoyance to the public using the highway. Evidence was given of the death from electric shock obtained from contact with the charged conductor of this tramway at various dates since the line was opened, of four horses and five head of cattle, besides injuries to other animals, and that in some cases payments had been made by the Tramway Company to the owners by way of compensation. This evidence was not seriously rebutted by the Tramway Company, whose principal scientific witness, Prof. G. F. Fitzgerald, M.A., F.R.S., of Trinity College, Dublin, admitted that in the present state of the line there is danger to cattle or horses driven along the road.

The complainants relied upon the finding of the coroner's jury as proof that the unfortunate death of Mr. Thomas Walne was due to electric shock. The Tramway Company, however, produced the principal witnesses examined before the coroner, to whom I read their evidence as given in the copy of the proceedings at the inquest supplied by the complainants, which they declared to be correct. I also examined these witnesses myself, and would draw special attention to the statements of Miss E. J. Adair that Walne was breathing naturally, and took brandy after the fall, turning up his face to obtain it; and of Dr. Huey, that in his opinion if there had been no current on the rail the man would be alive now.

The circumstances of the accident, so far as I was able to arrive at them, are that the deceased, Thomas Walne, was riding a bicycle along the road from Bushmills to Portrush about 7:30 p.m. on August 26, 1895. At a short distance from Bushmills he attempted to turn his bicycle on to the tramway, which is at this point separated from the ordinary roadway by a stone curb rising a few inches above the roadway. The machine striking against this curbstone, was upset, and Walne was thrown violently over the tramline and fell across the raised rail, which was electrically charged at the time, so that this rail was across the lower part of his chest, his hands and head probably touching the damp grass on the bank on the far side of the raised rail, one of his legs over the bicycle and the other under it, and the bicycle lying across the tramway rails. He was heard to shout three times as if in agony. His companion, who was about 100 yards behind him at the time, tried to pull him off, but was at first unable to do so on account of the shock he himself sustained. Finally, he accomplished his purpose by wrapping his mackintosh round his hands. Walne was then carried across the road and supported, while brandy was administered to him. He appeared to be conscious and was breathing naturally. He was able to swallow the brandy. Shortly afterwards he was removed to the station at Bushmills, where he was seen by Dr. David Huey. He had then ceased to breathe, but the heart was beating slowly. Artificial respiration was resorted to without effect, and he died about half-an-hour after the fall. Dr. Huey examined the body and found several marks of burning on and below the breast, but no post-mortem examination was held.

The complainants also produced scientific evidence proving disregard by the Tramway Company of the regulations for electric working imposed by the Board of Trade, and this evidence I am able to supplement from my examination of the line and generating station.

This witness, Mr. A. E. Porte, electrical engineer of Dublin, also suggested that the existing danger might be remedied by covering in the charged rail so as to prevent accidental contact with it, that the turbines at the generating station should be governed automatically, and that there should be a self-recording voltmeter at the station at Bushmills open to public inspection. I will deal with these suggestions later.

The evidence produced on behalf of the Tramway Company was to the effect that in numerous cases shocks had been received by human beings from the charged rail, in some instances contact being made for several minutes, without permanent injury.

Inspection of Line and Generating Station.

This inspection was made on the afternoon of September 25th. I found that the regulations imposed by the Board of Trade had been disregarded in many particulars, as follows:—Regulation 5, entirely disregarded. Regulation 6, entirely disregarded. Regulation 7. I do not consider the voltmeter in use efficient for the purpose, as although it appeared to be approximately correct in its indications, it was far too small to be read conveniently at the distance at which the man stands to regulate the current. Regulation 9, entirely disregarded. Additional regulation as to notices along the line insufficiently attended to. I only saw three such notice boards, and the inscription on these was almost obliterated. Bye-law IV., disregarded in the cars I saw.

I took several tests of the electric pressure at the station at Bushmills, being the nearest point of the line to the generating station, and at the generating station itself. The volts on the line varied considerably, the highest reading I obtained being 310, and the average about 290. At the station the readings were much the same. As the regulation was entirely by hand I tested what would be the effect produced by ordering the attendant to leave the regulating wheel alone, as if he had been suddenly incapacitated. Under these circumstances the pressure only rose to about 320 volts. The water was, however, rather low at the time, and at periods of full supply no doubt a greater rise of pressure might be produced; indeed, Mr. Boyd, the inspector to the Tramway Company, stated that the highest reading he had observed at any time at the generating station was 360 volts.

The charged rail appeared to me to be a decided obstruction, especially at road crossings, and in front of field gates, &c. It seemed to me hardly practicable for a man to drive a herd of cattle along the road, or into a field abutting on it, without great risk of one or more animals receiving a shock.

Conclusion.

Having carefully considered the evidence produced at the inquiry held by me, and the observations made at my own inspection, I am of opinion:—

(1) That Thomas Walne died from the combined effects of severe injury caused by the fall across the rail and electrical shock.

(2) That the tramways in question are at present, when the insulated rail is electrically charged, a danger to the public and an annoyance to the ordinary traffic.

(3) That the Giant's Causeway, Portrush, and Bush Valley Railway and Tramways Company have not paid sufficient attention to the regulations imposed upon them by the Board of Trade.

As to 1, I consider that the lethal effect of the electric current was due to the large extent of contact made by the body of deceased with the charged rail, the considerable pressure—viz., a large portion of the weight of a man of nearly 13 stone, with which the contact was made, and the length of time, at least several minutes, during which the current was passing through his body.

With regard to 2, it must of course be borne in mind that this electrical tramway was one of the earliest constructions of the kind.

In my opinion the danger that has undoubtedly existed has been largely due to the position of the charged rail at a height of about 18in. from the ground. Had this rail been placed at the ground level it would have been far safer than it is at present, while if it had been raised to a height of not less than 8ft. from the ground, and greater width of opening allowed at gateways and road crossings, I think that with proper regulation of the electric pressure the working of the line would have been practically free from danger. As at present arranged the charged rail is easily touched by man or beast, and the effect of the shock is exceedingly likely to cause a fall across the rail, which in itself must probably produce physical injury, and also such a contact of the body with the rail that the resulting electric current is large enough to cause death unless assistance should be given at once.

With regard to 3, the Tramway Company allege that they have found a practical difficulty in complying with some of the regulations imposed upon them by the Board of Trade. There may be some grounds for this statement, but this difficulty should have been brought to the notice of the Board of Trade with a view to the modification of these requirements, and even this excuse does not extend to all the failures on the part of the Company to comply with regulations.

Recommendations.

I recommend that the Tramway Company should be required, under the provisions of Section 20 of the Act of 1880, to remove without delay the danger and annoyance to the public which have been proved to result from their existing arrangements by adopting one of the following (three) remedies, viz.:—

(1). To remove the existing charged rail altogether, and adopt an overhead system, in which case the limit of electrical pressure might be reconsidered.

(2). To raise the existing charged rail to a height of not less than 8ft. from the ground.

(3). To effectively protect the existing charged rail as suggested by the complainants. This expedient, however, appears to me to be difficult to carry out, and in all respects the least desirable of the three.

The Tramway Company should also be required to exhibit in a conspicuous position at their Bushmills station an efficient and correctly indicating voltmeter connected to show the electrical pressure at this point of their line, and it is desirable that this should be arranged to make a continuous record, but in any case its indications must be clearly visible to the public.

Further, the Tramway Company should be called upon for a full explanation of the failure on their part to comply with the regulations made and imposed upon them by the Board of Trade.

In the meantime I think the Company, having regard to the danger which has been shown to exist, should discontinue their use of electrical power until they have carried out the alterations decided upon, working their line entirely by steam power for the present.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

MONDAY, November 4th.

NOW READY.—Vol. XXXV. of "THE ELECTRICIAN," bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

The published price of Volumes previous to Vol. XXXV. is 12s. 6d., post free 13s. 6d. Many of these Volumes are very scarce.

THE PORTRUSH ACCIDENT.

In another column we publish the full text of Major CARDEW's Report on the fatal accident to a venturesome cyclist which took place last August on the Portrush-Giant's Causeway line. The circumstances surrounding this fatality will doubtless be within the recollection of our readers, and they are, moreover, set forth in some detail in the Report. Suffice it to say here that on trying to surmount the kerbstone separating the tramway from the roadway, the cyclist was upset and was thrown on to the charged conducting rail, which runs alongside the line at a height of about 18in. from the ground; with his head and hands he apparently made contact with the damp grass on the bank beyond, and with his legs and his bicycle he made contact with the rails behind. Death was the result.

Although the Board of Trade Inspector's remarks cannot prove pleasant reading to the Company concerned, and although the carrying out of his recommendations will involve expense, we do not think any fair-minded individual can find much fault with the tone of the Report, nor cavil at the recommendations therein made. The evidence, after making all due allowance for the exuberance of the native imagination, showed sufficiently clearly that the Inspector does not overstate the matter when, in his second conclusion, he asserts "that the tramways in question are at present, when the insulated rail is electrically charged, a danger to the public and an annoyance to the ordinary traffic." And the correctness of that conclusion once admitted, the recommendation that the charged conductor should either be raised out of harm's way or effectively shielded, and that pending the carrying out of these necessary alterations the electrical working of the line should be suspended, cannot, having in view the fact that the line can be worked by steam, be deemed unduly harsh. The

Portrush line, it is true, is, electrically speaking of course, a mediæval structure; indeed, almost primeval, so early (September 28, 1883) in the history of electric traction did it first come into operation. The Company has, therefore, especially if we remember that the line is financially not an overwhelming success, much justification for its remissness in bringing up its methods and devices to the latest Board of Trade pattern; the Inspector, indeed, almost admits as much. At the same time such an excuse cannot be pleaded indefinitely, and it is not unreasonable that the Board of Trade should take advantage of an occurrence such as the one in question to insist on immediate compliance with its regulations, drawn up, it must not be forgotten, with the assistance of those likely to be affected by them. Cyclists *ought* not, of course, to try to jump kerbstones and ride along tram lines, but the sweet unreasonableness of human nature is a constant and well-known factor, and adequate precautions must be taken against it. There is, moreover, nothing of a circular-saw nature about a charged electrical conductor. Red paint and warning notices are all very well in their way, but they invariably fail to protect just when they are most wanted—that is to say, in moments of forgetfulness and foolhardiness. A plain rail, raised a few inches off the ground, separated from the roadway by a kerb of fewer inches still, looks so entirely innocent that, notwithstanding the Education Act of 1870 and the latter day spread of technical knowledge, an adventurous cyclist may very well be excused for not realising the presence of danger: the danger of a too close proximity to a circular saw is, on the other hand, obvious to the meanest comprehension.

"Ill blows the wind that profits nobody," and this Inquiry will not have been altogether in vain if it arrests once for all the quest after the minimum voltage that is necessarily fatal. It is certain that the unhappy cyclist was not exposed to a greater pressure than 400 volts, and was probably exposed to a much lower pressure. His death is one more evidence that in such cases it is not nearly so much a question of voltage as one of condition of health, of duration and goodness of contact, and of the power at the back of the volts. Again, the belief prevailing in the country side that the line was frequently charged to an abnormally high potential, has also been satisfactorily dissipated. Likewise we may venture to hope that the recent fatality will put a stop to the pleasant practice, which obtained, we understand, amongst the country folk living near the line, of making use of the charged conductor as a source of medicinal shocks. Last, and by no means least, the Report of Major Cardew should serve to bring home to some of our central station managers the fact that the plea of the impracticability of the rules will not avail them if mishaps, for which Board of Trade electric supply rules provide, occur. Rules and regulations the Board of Trade are bound by law to impose; so that it is of no use to grumble at their imposition. And these rules and regulations are, moreover, bound to be stringent, to satisfy the public and —to save the Board of Trade in the day of trouble. The only thing to be done is to take the fullest possible advantage of the Board of Trade invitation to discuss and amend. If, after all, conditions are laid down which central-station engineers disregard as being impracticable, the blame for accidents traceable to non-compliance will inevitably fall directly on the shoulders of the central-station engineers. Success alone justifies defiance of constituted authority. The natural rigidity of Governmental rules has up to now been considerably tempered by judicious blindness, on the part of the powers that be, to well-intentioned infractions. But when mishaps arise no Government Department, no matter how desirous it may be not to unduly hamper an infant industry, can publicly condone disobedience. The position is an awkward one, but whether it is more so for the central-station manager than for the unlucky Department that is expected to legislate in advance, and provide for all possible contingencies, we should be sorry to say.

THE JANDUS ARC LAMP.

In response to the invitation of Messrs. Drake and Gorham we visited, on Thursday, the 24th ult., their works, adjoining those of Messrs. Johnson and Phillips at Old Charlton. Here special machinery has been put down for the manufacture, in large quantities, of the above arc lamp, the invention of Mr. Jandus, and it was with the object of inspecting the working of the lamp, the principle of its action and the facilities for its manufacture, that we paid our visit.

It is claimed that in this lamp we have one which, with a single pair of carbons, will run without retrimming for 200 hours. Also, that it will run singly in parallel across 100-volt constant-potential circuits without waste of power; or, when specially adapted for thus working, in series on constant-current circuits, requiring in the latter case an E.M.F. per lamp of about 75 volts. On the occasion of our visit we saw lamps running in parallel taking currents from 2½ amperes up to 6 amperes. They all seemed to burn very steadily during the time we had an opportunity of watching them.

The method by which this extended burning life of the carbons is obtained consists in enclosing the arc by closely fitting globes, so that during the greater portion of the time the arc is in existence it is surrounded by an atmosphere almost wholly destitute of oxygen. The lower and negative carbon rod—which does not move, and is about 7in. long—is fixed in a holder connected with the negative terminal of the lamp. Resting on a seating in this holder, and kept down by a thumbscrew in such a way that little or no air or gas can enter from below, is a small globe, high enough to enclose the arc and to reach about 1in. above it when the carbons are new. The top of this small globe is closed by a steel cap, with a hole in the centre sufficiently large to give clearance for the upper and positive carbon rod to feed easily and without any friction into the globe. Outside the small globe and enclosing it is a larger one, which is made airtight at the top by being gripped by the rim of its opening between asbestos packing rings. The bottom opening of this globe is closed by an inverted-saucer-like valve, which is pressed up against the flared opening of the globe by a spring so as to allow egress, but prevent ingress, of air. When the arc is formed the heat expands the air in the globes, the surplus escaping through the valve in the large globe. Soon the air inside is robbed of its oxygen, the latter uniting with the carbon to form CO and CO_2, the globes ultimately being filled solely with (probably) CO and the unaltered nitrogen. As a result the rate of combustion of the carbons is very slow, enabling one pair of ½in. carbons, 12in. and 7in. positive and negative lengths respectively, to last, with a current of 4 amperes, for 200 hours.

The illustration, Fig. 1, well shows the negative carbon holder and the spider, which enables it to be attached to the negative framewood of the lamp by a sort of bayonet joint, after having been withdrawn for the purpose of cleaning and recarboning. In the upper part is seen the small opal globe with its steel cap in place, through the hole in which has been inserted the positive carbon, after having been fitted with its brass tube holder. In the lower part is shown the brass saucer-shaped disc which acts as a valve to the large globe. The whole arrangement shown in the cut is ready for insertion into the lamp from below, through the opening in the large globe, which, for the purpose of retrimming and cleaning the lamp, does not need to be released from the main framework to which, as stated above, it is fixed airtight.

Since the positive is the only moving carbon, the lamp is non-focussing. The regulating mechanism will be best under-

stood by reference to the accompanying sectional sketch (Fig. 2), which is merely indicative of the general arrangement of the gear, and does not in any way represent the actual proportional sizes of the parts indicated, nor even their particular shape, except in a general way. The solenoid carrying the main current is shown at *s*. Inside this is a hollow core, *a*, fixed by screws to *b*, which slides into a brass-lined dashpot, *c l*. Firmly fixed to *c* is a brass tube, *g*, over which slides easily the dashpot piston *b*. Four slots (two of which the section shows at *e e*) are cut in the lower end of the core *a*, wide enough to admit loosely the milled brass rings *d d* in the position shown. To keep these four rings in place an iron wire ring *w* is threaded through them and encircles loosely

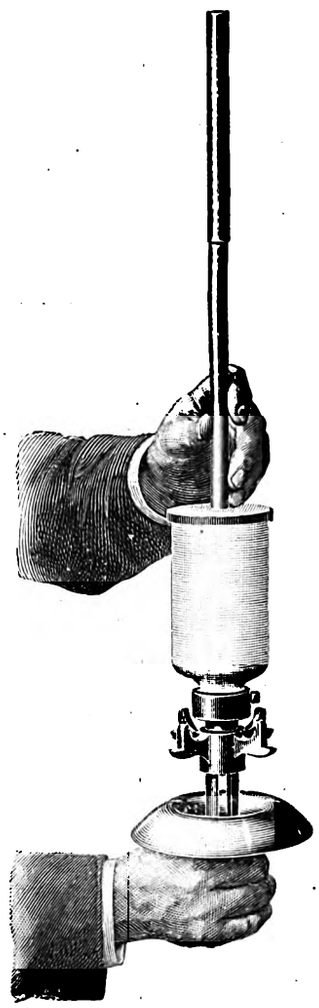

Fig. 1.

the round core *a*. The positive carbon *p* carried in the split end of the brass carbon holder *h* after it has been pushed into the holder against a shoulder. When the lamp is idle *s* has no power to uphold *a* and *b*; therefore *b* is in its lowest position, and the clutch rings *d* rest on the top of the brass tube *g*. The carbon *p* and its holder is then free to fall into contact with the negative carbon. When, however, current is switched on, *s* sucks up *a*, the rings *d* fall or roll towards the carbon *p*, and ultimately grip it, lifting it with *a* and striking the arc. When the arc gets (by consuming the carbons) abnormally long, *b* has dropped low enough for *g* to free the pressure on *p* of the rings *d* and then *p* slides to feed.

To keep the carbon centred, lower down, and also to perform the function of supplying it with current, the device *n n* is used. It is shown in the sketch detached from the main body of the lamp, but in reality it is fastened by *n n* to the lamp; *n m m n* is an annular brass ring, notched on its inner and outer circumferences to a certain depth, leaving a continuous portion *m m*, on which are strung a number of brass rings, *k*, with their planes radially disposed. To keep them radially and symmetrically spaced is the function of the notches in the ring *n n*.

These rings *k*, by their weight, all fall against the carbon rod or its holder (when it has fallen so far), and before it can move sideways has to elevate all the rings on that side. The brass carbon holder *h*, cannot, like *p* the carbon, pass through the hole in the steel cap of the small globe, so that the lamp is cut out when *h* has fallen so far that it rests on the cap.

We learn from a prospectus of the lamp that "the mechanism contains neither . . . dashpots . . . nor carbon rods." We should be perplexed in the use of this lamp if the parts which certainly act as a dashpot were removed, and if we were not allowed the use of carbon rods.

For parallel working, which seems the special field for which this lamp is adapted, the regulating solenoid is a series coil carrying the main current, and is iron-clad. The voltage across the arc is, in the 4-ampere lamp, about 75 volts. In the framework of the lamps intended for working in parallel is fitted a resistance (insulated with asbestos) which absorbs 20 volts. We were told that the lamps for working in series on constant-current circuits were fitted with a shunt coil in addition; and placed co-axially with and on top of the series coil, these, with 5 amperes, take 75 volts per lamp.

The length of the arc is about from $\frac{3}{8}$in. to $\frac{1}{2}$in., and even this length burns steadily without apparent flaming, a condition

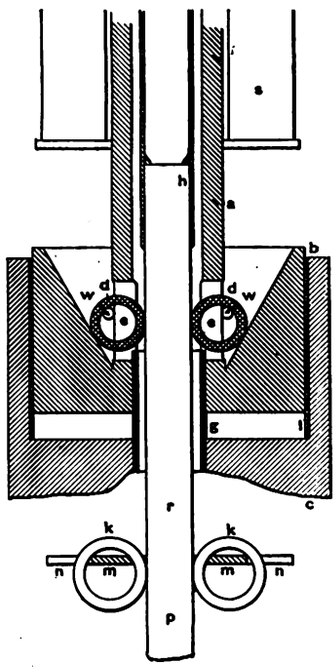

Fig. 2.

probably promoted through the prevention of convection and other currents of air by the closely-fitting globes.

This extra length of arc requires a difference of potential of about 30 volts in excess of that required in the old and usual length of $\frac{1}{8}$in. or $\frac{1}{10}$in. Since the source of by far the greater portion (about 80 per cent.) of the light emanating from an arc lamp is the crater, it is difficult to see the reason why such an abnormal length of arc is used in the "Jandus" lamp; unless it is expected by this means to overcome that very literal *bête noire* of all former efforts to produce a practical lamp on this principle—the blackening of the enclosing globe, due to the condensation of carbon vapour. Mrs. Ayrton has recently shown by her experiments on arcs that as the current is decreased so is the potential difference across the arc for a certain length of arc increased, and so is also increased the rate at which the potential difference increases with increase of length of arc. Therefore, if keeping the current fairly low and the potential difference across the arc high are the conditions under which blackening is got rid of, we shall expect to

Digitized by Google

find (when experiments of efficiency are concluded) that it has only been done at a sacrifice of efficiency.

Since the negative carbon is the same size as the positive one, it is doubtful whether the gain in distribution of light due to the extra length of arc is so great as it would be if the negative carbon used were a size smaller than the positive. Moreover, the diffusing action of the opal globe tends to shift the centre of distribution of the light from the crater to the surface of the globe, thereby rendering the shielding effect of the negative carbon of less importance.

Against the probable low efficiency of this lamp we find qualities which for certain purposes will tend to make it a success, viz., a very much lower cost of carbon renewals and labour, the possibility of using a low current, and the convenience of being able to connect the lamps singly across circuits of 100 volts. For lamps burning 10 hours per night for a year the length of carbon used in the old form to that in the "Jandus" lamp is something like as 560ft. is to 35ft. The carbons burn fairly flat instead of pointing and cratering on the negative and positive poles respectively. This result was to be expected when we take into account the long arc, the low value of the current, and the absence of an atmosphere surrounding the arc conducive to combustion. Prof. Silvanus Thompson has shown that the result of surrounding the arc with chlorine or carbonic oxide is that the carbons burn flatter, with a less perfectly developed point and crater. These results, together with state of the carbons in the "Jandus" lamp, seem to prove the truth of the suggestion, which was made some time ago, that the cause of the peak on the negative carbon is the absence of an oxidising agent in that region. Mrs. Ayrton has lately shown that the negative is less pointed the smaller the current and the longer the arc. These three reasons for the flat burning of the carbons are all concurrently present in the "Jandus" lamp in a high degree, compared with the usual arc lamp.

Until we have the results of experiments to determine the efficiency of this new lamp it is useless to speculate as to its fitness for public lighting on a large scale. In any case there would seem to be a field for its use as what may be termed a domestic arc lamp for the lighting of shops and shop windows, where nightly attention to trimming is an inconvenience. It would seem also, from the fact of its being so perfectly enclosed, that it would be a good lamp for factories, in which the air is dust-laden, and frequently so much so as to be combustible.

We were told while at Charlton that the success of this lamp in the United States has been great, and that the Edison Company, who attend to the trimming of their consumers' lamps, allow a rebate of 10 per cent. to those who use the "Jandus" lamp, on account of the saving it affords the Company in trimming.

STREET LIGHTING BY ARC LAMPS.*

BY ANDRÉ BLONDEL.

(Continued from page 849, Vol. XXXV.)

Simplified Means of Evaluating the Useful Effect of an Arrangement of Public Lamps.

The definition of the useful effect of public lighting is a very important point in connection with plans and contracts for lighting, for following the usual rules for these, one can arrive at absolutely different results, and the application of this or that seemingly insignificant condition is often followed by grave consequences. Up to the present engineers have sought to characterise the useful effect by a single photometric quantity. This we believe to be wrong, for we have just seen that the consideration of the single kind of illumination is insufficient. Nevertheless, it is possible that in practice it may be found advantageous, on account of its simplicity, to be content with an incomplete notion, seeing that it gives an idea which approaches somewhat to the very complex quantity which it is desired to measure. Let us, then, examine from this point of view the different solutions which have been successively proposed. Previously, the useful effect was defined from the plane surface illuminated and the minimum horizontal illumination realised. In contracts the value of this minimum, which was considered sufficient for the needs of traffic, was indicated, and it was required simply that the undertakers should light the given surface without going below this minimum. This was in particular the well-known system of the railways of the Belgian State. This left to the *concessionnaire* absolute freedom in the choice of the height and the distribution of the sources of light. In these conditions it was very advantageous for the undertaker to exceed this minimum by the least possible amount, and in consequence to use small lights very close together, and to adopt gas in preference to electricity. M. Weissenbruch, in a work which has become classical,[14] has shown the inconvenience of such a condition, which, if it is taken as the only condition, does not take into account the superabundant light emitted by large lanterns at short distances. This, from experience gained, should not be considered useless. M. Weissenbruch has concluded from this that it is necessary to take into account the mean illumination of the illuminated surface. To calculate this M. Wybauw has introduced a new notion, that of "volume of illumination," to which he has been led by combining the isolux curves drawn on the plan of the illuminated surface with the curves of the levels defining an imaginary topographical surface as previously indicated. The volume comprised between this surface and the zero line constitutes the volume of illumination, and it is obtained by successively measuring with the planimeter the zones of equal illumination. The mean ordinate of this volume is a measure of the mean illumination. It is by this classical method that M. Maréchal obtained the mean illuminations of the highways of Paris. (We give later on the very interesting results of these calculations.) This method has the great advantage of more fairly re-establishing the balance in favour of large lamps, since it takes account of the illumination produced at all distances.

But the considerations by which it is proposed to thus arrive at the idea of the mean illumination are, as I have already often stated, calculated to give a false idea of the physical quantity which represents the volume of illumination. This is simply the total *flux of light* which the illuminated plane receives,[15] and it is consequently independent of the direction of the illuminated surfaces, while the definition of the volume of illumination seems to consider exclusively the horizontal illumination. The mean illumination has no need of any complicated definition; it is simply "the ratio of the total luminous flux received by a surface, to the area of that surface."

Determination of the Useful Flux of Light.

All the writers whom I have quoted measure the horizontal illumination at the level of the roadway. They thus implicitly admit that the pavement is the only part of the public thoroughfares which it is important to illuminate. I am of opinion this is an erroneous hypothesis, for it is also very necessary that the passengers on the footpaths should be able to see each other and find the doors of their houses. The light may then be considered as useful at least up to 1·50 metres above the roadway in all cases, and we shall see still further that this is very often insufficient. Doubtless this consideration has led Herr Wedding[16] to measure the horizontal illuminations on a plane situated at 1·50 metres above the pavement, but this writer has not appreciated the fact that the horizontal illumination does not apply to these conditions, for there is not a single object to illuminate horizontally at 1·50 metres above the ground. If we take the plane of illumination as

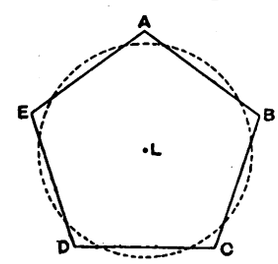

Fig. 11.—Approximate determination of the flux at a spot illuminated by a single lamp.

1·50 metres, or, better, at 2 metres, it should be but to measure the total flux which traverses it. Whatever may be the horizontal plane chosen as a limit, the flux that it receives can only be calculated exactly by means of the isolux curves, described a little higher. But under this form the method is very laborious, so that we content ourselves very often with more rapid approximate valuations, which are perfectly justifiable in problems of this nature, where to seek extreme accuracy would be useless. For instance, in the case of an arc L placed at the centre of an irregular place—A B C D E (Fig. 11)—one can take

* From *Le Génie Civil.* Translated by Mr. John Hesketh.

[14] "Comparison of Various Schemes for Lighting an Open Space," *Bulletin de la Société Belge des Electriciens*, 1889.

[15] The quantity chosen as the unit of illumination by M. Maréchal, under the name of "*are-bougie-mètre*," is in reality a *flux* of 100 lumens, and the "*are-bougie-mètre-heure*" is a *quantity of light*—the "*hecto-lumen-heure*."

Digitized by Google

as the useful flux that which is contained in a cone of revolution which cuts the vertical of B at a height of 2 metres. This cone being determined by its angle, the corresponding flux is measured on the polar curve in the manner indicated previously. In more complicated cases, where there is a series of lanterns distributed in any manner whatsoever, to obtain the mean illumination, it is not necessary to draw the isolux curves of the resultant illumination. It is sufficient to measure separately the useful flux produced by each lantern and to add these results. It is then very easy to make the calculation, for the isolux curves of each source are circles, of which the area is easy to determine.

To explain more clearly this process, I will take an example. Take a rectilinear street (Fig. 12), having a breadth $C_0 D_0 = b = 35{\cdot}20$ metres, illuminated by lamps L_1, L_2, L_3, placed 6 metres

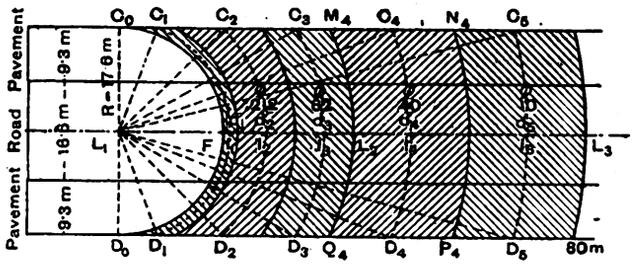

FIG. 12.—Determination of the useful luminous flux in a street.

high in the centre of the street, and the distance between them a equal to 40 metres, and of which Figs. 13 and 14 are the polar curves of the luminous intensity.[17] It is required to find the useful flux on an illuminated plane situated on the pavement. We will trace in vertical projection on Fig. 15 the curve of the distribution of horizontal illumination due to L_1 in the vertical plane, passing through L_1, L_2, L_3, the illuminations being determined at 6 metres below the lamp. We will suppose that the illumination at a greater distance than about 80 metres, for instance, is negligible. We then describe on the horizontal plane a series of isolux circles, starting with a circle of radius r equal to 17·60 metres and tangent to the houses. This forms the base of a

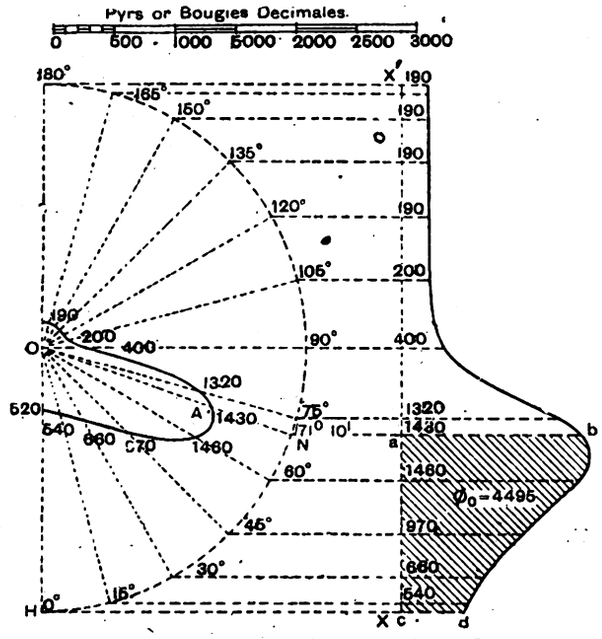

FIG. 13.—Photometric polar curve of luminous intensities of a 10-ampere continuous-current arc placed under a 34cm. holophane globe.

FIG. 14.—Curve of corresponding luminous flux.

cone, of which the half angle at the apex, determined by its tangent $\frac{17{\cdot}6}{6} = 2{\cdot}932$, is 71° 10′, and the half flux ϕ_0 contained in this cone is, from Fig. 13, equal to $\frac{4,495}{2} = 2,247$ lumens. We may assume that in each of the shaded zones of Fig. 12, such as M_4, N_4, P_4, Q_4, the illumination is equal to the mean value E_4, corresponding to the dotted circle $C_4 D_4$, and may take as an approximate expression for the surface S_4 of this zone the product of the length of the arc of the circle $C_4 D_4 = a_4 r_4 = l_4$ into the width of the zone d_4.

We shall thus find for the half flux ϕ in the different zones 1, 2, 3, 4, 5 the approximate values given by Table III. below. From whence the total flux :

$$\phi = 2(\phi_0 + \phi_1 + \phi_2 + \phi_3 + \phi_4 + \phi_5) = 5,386 \text{ lumens.}$$

This only applies to a single lamp. To reckon the total effect, without taking into account the effect of the ends of the street, it is sufficient to suppose these indefinite. Then if n is the number of lamps it contains, the surface illuminated is $n\,b\,a$, and the mean illumination is simply $\frac{\phi}{ba}$, that is to say, the ratio of the flux produced by each lamp to the surface of the rectangle comprised between two consecutive lamps.

We shall then have as a mean illumination

$$E_m = \frac{5,386}{40 \times 35{\cdot}20} = 3{\cdot}82 \text{ lux.}$$

Planimetering direct from the isolux curves reproduced later, we get $e_m = 3{\cdot}90$.

We thus see that the approximate method gives a result which is sufficiently exact, and since the flux ϕ_0 is preponderant, it is sufficient to determine very roughly the following fluxes by reducing the zones investigated to 2 or 3 only (Table III.). If we had

wished to calculate the useful flux at any height h', we should have made the same calculation, only determining the illumination at a

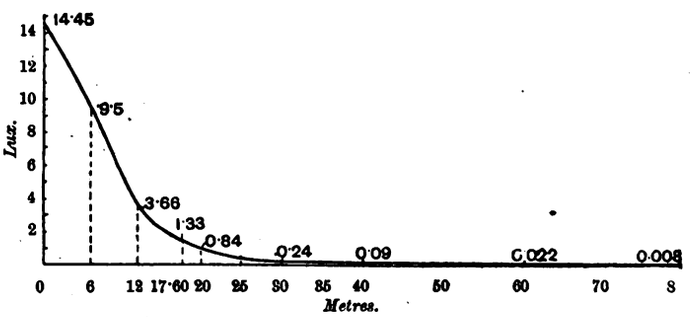

FIG. 15.—Curve of horizontal illumination due to a 10-ampere continuous-current arc, placed under a 34cm. holophane globe.

plane situated at $(6m - h')$ below the lantern. We should have thus found a flux $\phi' > \phi$, and the mean illumination of the entire lighted surfaces would have been

$$\frac{\phi'}{b\,a + 2h'a} = \frac{\phi'}{(b + 2h')a},$$

the two heights of the houses being added simply to the width of the street. Thus, in many cases, we may, I think, go yet still further, and consider as useful all the light emitted in the space below the horizontal plane passing through the luminous focus; for the illumination of frontages, trees, &c., up to a height of 7 or 8 metres, is almost always advantageous, not only because it allows of the diffusion of light, but also because it permits the eye to take in the whole of a street, and the buildings which enclose it. We may then take, as a measure of the useful flux, all the lower hemispherical flux, which is given directly by the polar curve. This method will give us figures erring a little occasionally in excess,[18] but it is so simple that its use is to be recommended. It is, besides, the most equitable in straight streets, where houses are well illuminated. Since we shall then have calculated the total number of *lumens* reckoned as useful it will suffice to

[17] The curve chosen to illustrate this is that of a 10-ampere arc placed under a holophane globe of 34 centimetres, as used in the Grand Boulevards.

[18] But very little, in the case of the continuous-current arc; for in the preceding example, instead of 5,386 lumens, we should have 6,610, or 13 per cent. more.

Digitized by Google

divide this number by the total surface illuminated to have the general mean of the illumination in *lux*. In the preceding example the lower hemispherical flux is 6,610 lumens from the polar curve. The total surface illuminated is, for one lantern, 40 (35·2 metres + 2 × 6) = 1,888 square metres. The mean illumination of the entire street is then

$$E_m = 3{\cdot}50 \text{ lux.}$$

M. Wybauw has introduced a modification into the calculation of the mean illumination, which consists in assuming a uniform value (value of the illumination along the 45deg. line) for the illumination at the level of the foot of the lamp-post within a cone of 45deg., on the pretence that, if the illumination is greater, it does not count for anything. This view of the matter has been objected to in general by specialists, but without solid arguments. We hope to show by that which follows that this view should not be entertained when considering the lighting of public ways, and at the same time we hope to destroy a widespread prejudice relative to the distribution of light.

Choice of the Best Distribution of Light for Public Lighting Purposes.

That which characterises all the sources of light actually employed for public lighting is the superabundant illumination which they produce in the immediate vicinity of the foot of the lamp-post. The result of this is almost truly a spot of light with edges more or less defined, outside of which the illumination follows an extremely

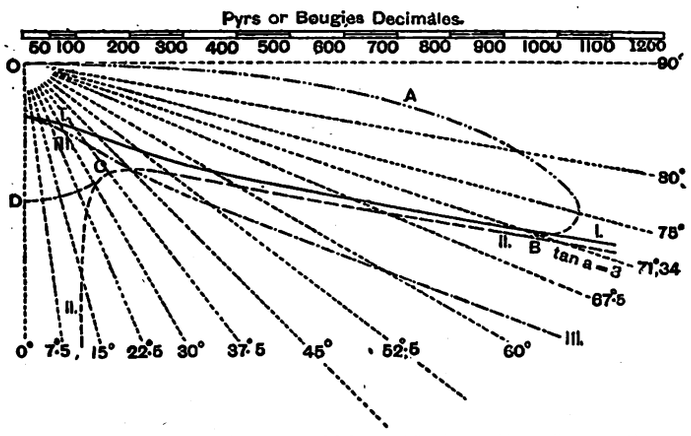

Fig. 16.—Photometric curve which would give uniform illumination on a horizontal plane. I.—Curve for uniform normal illumination. II.—Curve for uniform vertical illumination. III.=Curve for uniform horizontal illumination. O A B C D—Ideal photometric curve.

rapidly decreasing law. This fact has long since struck all the engineers who are interested in lighting, and they have all been in unison in criticising it and expressing the view that one should distribute the light more rationally; not lavishing it at the foot of the lantern, but utilising it in the more distant parts of the street, which are those generally cheated. If we take the horizontal illumination as the characteristic of lighting, the solution which appears at first to be the most perfect is to endeavour to obtain for it a uniform value, and those specialists who endeavour only to illuminate the ground resolutely accept this proposition as the desideratum for each of the lamps taken separately. The curve of the distribution of luminous intensities which obtains this result has, as we know, the following equation: $I_\alpha \cos^3 \alpha = \text{const.}$ This form is represented in Fig. 16, curve III. It is this curve which Mr.

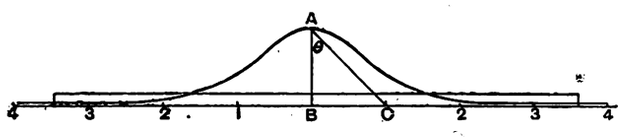

Fig. 17.—Effect of making the horizontal illumination of a source uniform, the luminous flux remaining constant. (The undulating curve represents the illumination before "uniformisation," and the small rectangle the illumination made uniform.)

A. P. Trotter endeavoured to obtain in 1892 with the assistance of his apparatus, of which we shall speak later; but the little appreciated results of this experiment and a more exact knowledge of the desiderata for ordinary foot passengers should make it known to-day that an uniform illumination would not have a single chance of success in the present state of our resources; and even if we obtained it its partisans would quickly abandon it on account of the opposition of the public, for the public is indifferent as to the uniformity of the illumination. They wish to have a street not only moderately well lighted as a whole, but also to have some places more brilliantly illuminated. This would no longer be the case immediately we distributed the same flux of light uniformly, unless the slight increase of the minimum illumination which would result was sufficient to compensate for the loss of the maximum illumination. To enable us to make a calculation, let us take, for instance, the most simple case—that is, a lamp having the same intensity I in all directions, and let I equal 500 pyrs; let us place it at 6 metres high, and let us use it to illuminate a circle having as a diameter seven times that height.[19] The curve of the horizontal illuminations has the form represented by 4 A 4 (Fig. 17).

The flux of light ϕ emitted in the cone with an aperture of 74° 12′, corresponding to the circle with a base of 7 metres, is here very simply the product of I into the solid angle of the cone

$$\sigma = 2\pi (1 - \cos 74° 12'). \text{ [see No'e 20.]}$$

We find, then, $\phi = 4{\cdot}5\ I = 2{,}250$ lumens.

The surface illuminated being $\pi (21)^2 = 1{,}320$ sq. metres, the mean illumination $= \frac{2{,}250}{1{,}320} = 1{\cdot}7$ lux, while the minimum and maximum illuminations determined directly are, respectively,

$$\frac{500}{6^2} = 14 \text{ lux and } \frac{500}{6^2 + 21^2} = 1{\cdot}05 \text{ lux.}$$

In consequence, by making the illumination uniformly 1·7 lux, which corresponds to the small rectangle in Fig. 17, we shall gain only 0·65 lux on the minimum illumination, while the maximum would fall from 14 to 1·7 lux. The public is much more sensible of the second effect than of the first, and in consequence would find the street less perfectly lighted. This apparent diminution of lighting would be more marked the greater diameter of the circle, for the curve of distribution shows that the ratio of the vertical intensity to the oblique diminishes very rapidly.

(To be continued.)

[19] This is the condition assumed by Mr. Trotter, and Fig. 17 is borrowed from his interesting paper on the Uniform Distribution of Light.

[20] The solid angle σ is defined as the surface intercepted on a sphere of radius 1. It is deduced from the known expression for the surface of a spherical zone $2\pi r (1 - \cos \theta)$.

THE ELECTRIC LIGHTING OF EDINBURGH.*

BY HENRY R. J. BURSTALL.

The electric lighting of Edinburgh, as is also the case in many of the most important towns in England and Scotland, is in the hands of the Corporation; and was finally decided on late in 1893, when the work of designing and superintending the whole scheme for public and private supply was entrusted to Prof. Kennedy. Work was commenced at the station and in the streets in May, 1894, and the station was opened for the continuous supply of electrical energy on April 11, 1895, the exceptionally severe winter having seriously delayed the progress of the station buildings.

Districts.—From the electrical point of view the City of Edinburgh may be said to consist of two districts, differing from each other both in character and in their positions relative to the centre of the city. The older part of the city by the Castle, and the district north of Princes-street, include the greater part of the business premises, together with a residential district in which the houses are large and closely built, and where the demand for current may be expected to be great. The district to the south and east of the central porton is either residential or of such a character that the demand for current can never be as large as that in the northern and central district. The residential part of this district contains many houses which stand detached from one another, thus diminishing considerably the possible number of lamps in proportion to the frontage. Having regard to the different districts to be served, and taking into account all the local circumstances, it was decided, after comparison of the various systems of supply and distribution which could be used, to adopt a low-tension three-wire system for the central and northern district, and an alternating-current high-tension system for the southern and eastern district, both systems being worked from one central station and under the same control and management. A good site was found for the central station between the Caledonian Railway and Dewar-place. The foundation here is rock; and the station being on the railway, coal is brought direct into the boiler house in the railway trucks at a minimum of expense. The position of the site is such that, while being fairly central, it is in a neighbourhood where there is little chance of complaint as to nuisance, real or otherwise.

Station.

The building, which is a handsome brick erection with brown stone frontages to Dewar-place and Torphichen-street, is from the designs of Mr. J. Cooper, the burgh engineer, and was erected under his superintendence. The site is roughly triangular; the

* Paper read before the Institution of Mechanical Engineers.

Digitized by Google

boiler house occupies nearly the whole of the north side, and the two engine rooms are parallel to and south of it; the general offices occupy the extreme south of the site, and are large enough for the accommodation of the whole of the clerical staff, as well as for the resident engineer and his assistants. Above the boiler room are the workshops, and the floor above the western end of the engine rooms is used for the battery room, store room, and meter store and testing rooms. The eastern part of the engine room is covered with a light iron roof, with ample provision for light and ventilation. The boiler room is covered with a concrete floor, which will ultimately be used as a coal store. There is ample space in the buildings at present erected for considerable extensions without any extra outlay beyond the foundations for new engines and boilers.

Boiler House.—The boiler house (Figs. 1 and 2) is 158ft. long by 48ft. wide, occupying nearly the whole of the north side of the site.

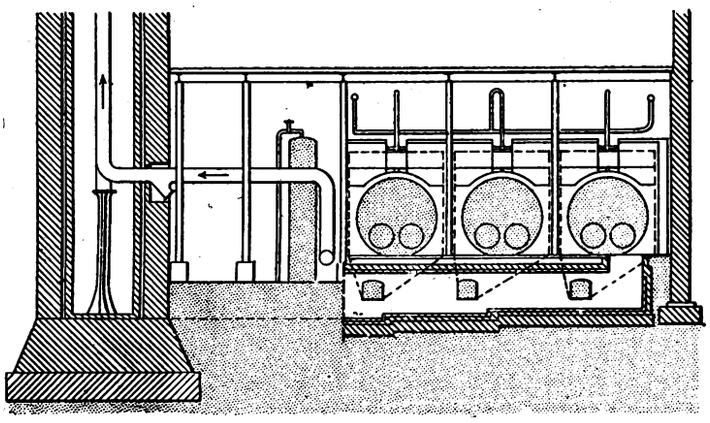

FIG. 1.—Boiler House.

It is designed to contain 17 boilers, of which at present only the six at the west end are in place. The main flue runs along the centre under the stoking floor into the chimney, which is placed in the centre of the length of the house, and is 8ft. square inside and 160ft. high, being lined with firebrick for a height of 60ft. The side flues from each boiler enter the main flue at a slight angle, and each flue is fitted with a butterfly damper; a damper is also placed in the main flue close to the chimney.

action of the gases. The steam circulates from a standpipe on the boiler to the back leading pipe, through the superheated tubes to the cast-iron pipe at the front, and thence to the main steam pipe; proper valves are arranged so that the superheater can be entirely shut off and the steam be taken direct to the main steam pipe. Each superheater is fitted with a safety valve and draining cocks. The superheater coils are readily accessible for cleaning and examination by doors at the front and by movable plates at the top; or, if necessary, they can be lifted bodily away from the boiler. The course of the furnace gases is from the furnace to a brick combustion chamber at the back of the boiler, through the boiler tubes to a wrought-iron smoke box at the front, thence up and along the top of the boiler, past the superheater tubes to the back, and there down each side to a centre flue under the bottom of the boiler. A damper is provided, by which the gases can be sent direct to the sides of the boiler without passing the superheater tubes. Sinclair's mechanical stokers are fitted to each boiler, and are worked from two lines of shafting, which are carried by the columns of the boiler house and driven by an electric motor.

Steam is taken from each boiler through a standpipe, with valves to the superheaters; and from the latter through a large copper bend to the main steam pipe, which forms a complete ring round the present boilers. This ring joins the engine room main at two points, and is provided with valves, so that the failure of any one pipe will put only the corresponding boiler out of use. Drain valves are placed wherever water may accumulate, and are all connected to a steam trap which returns the condensed water to the feed tank.

The pump room is opposite the chimney, and is entirely closed in. It contains at present one duplex steam pump and two three-throw pumps driven electrically; each pump has a maximum capacity of 4,500 gallons per hour. The electrically driven pumps are specially designed to run with a large range of speed; and for this purpose can be connected with either the 230-volt or the 115-volt mains. The steam pump has its steam supply connected with two points of the main steam pipe, and its exhaust is connected with the feed heater. Each feed pump has an independent suction from the feed tank, and two independent deliveries into two separate lines of pipes, each of which can be connected with either range of the two duplicate rings of feed pipes, either through the feed heater or direct. The duplicate rings of feed pipes are carried round the stoke hold in chases in front of the boilers; and each boiler is connected with both rings of pipes by separate feed check valves delivering into a common internal pipe. A Kennedy water meter is connected with one range of feed pipes, so that the whole of the water going to the boilers can be measured. In the pump room is

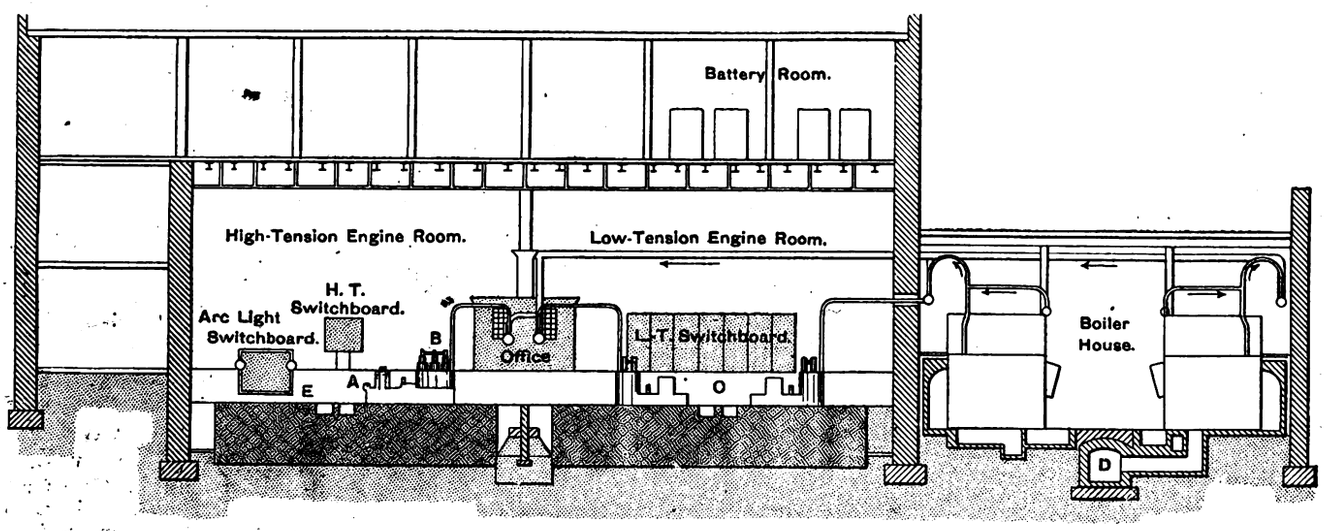

FIG. 2.—Engine Rooms and Boiler House. A, alternators; B, 150-I.H.P. engines; C, 100-I.H.P. engines; D, main flue; E, Rectifiers.

The boilers are of the dry-backed marine type, each 10½ft. mean diameter and 12ft. long, with two Purves flues, 3¼ft. inside diameter, and 166 tubes of 3in. internal diameter. The boilers are of steel, with wrought-iron tubes, and have been built in accordance with Board of Trade rules for a working pressure of 160lb. per square inch above atmosphere. They are fitted with the usual mountings, and have duplicate feed check valves.

On the top of the boilers are fitted superheaters, each consisting of two nests of tubes enclosed between the top of the boiler shell and a fire-brick casing above, with a space left in the centre for the steam valves, safety valve, &c. Each superheater consists of 32 vertical flat coils of wrought-iron tube 1½in. diameter, running from a large cast-iron pipe at the back of the boiler to a similar pipe at the front, all joints being outside and protected from the

placed the electric motor for driving the mechanical stokers with its countershaft; and there is ample space for more pumps when they are required.

Under the pump room is the feed tank, which communicates with a large storage tank at the end of the boiler house; another feed tank is also provided under the workmen's room, so that there is an ample reserve of water in case of accident to the water supply. A siding from the Caledonian Railway runs into the boiler house, and the coal brought in the railway trucks is at present stored in the east end of the boiler house; on the station being extended, the coal will be stored over the boiler house, and let down through shoots to the mechanical stokers. In designing the plant at present in the boiler house, provision for extensions has been kept in mind; and the arrangements are such that new plant can be added at any

Digitized by Google

time, without interfering in any way with the working of that already in use.

Engine Rooms.—The engine rooms (Figs. 2 and 3) are each about 102ft. long, and are side by side, forming really one room divided by a line of columns which carry the roofs and the beams for the travelling cranes. The engine room next the boiler house is reserved for the low-tension plant, and is 46½ft. wide; the other contains the high-tension plant, and is 41½ft. wide. A platform, raised 4ft. above the engine room floor-level, runs the whole way across the west end of both engine rooms; and on this are placed the switchboards and regulating gear for both the low and high-tension systems, as well as the office of the engineer on watch.

Low-Tension Engine Room.—The machinery at present in the low-tension engine room (Figs. 2 and 3) consists of eight engines, four of 100 I.H P., two of 250 I.H.P., and two of 360 I.H P., with their dynamos; and provision is made for eight more engines of 360 I.H.P. in the future. All are Willans central-valve engines driving their dynamos direct. All the dynamos are two-pole shunt-wound machines with drum armatures, all wound to give 270 volts, except two which are driven by two 100 I.H.P. engines; these two are wound to give 135 volts, being used as balancing machines on the three-wire system.

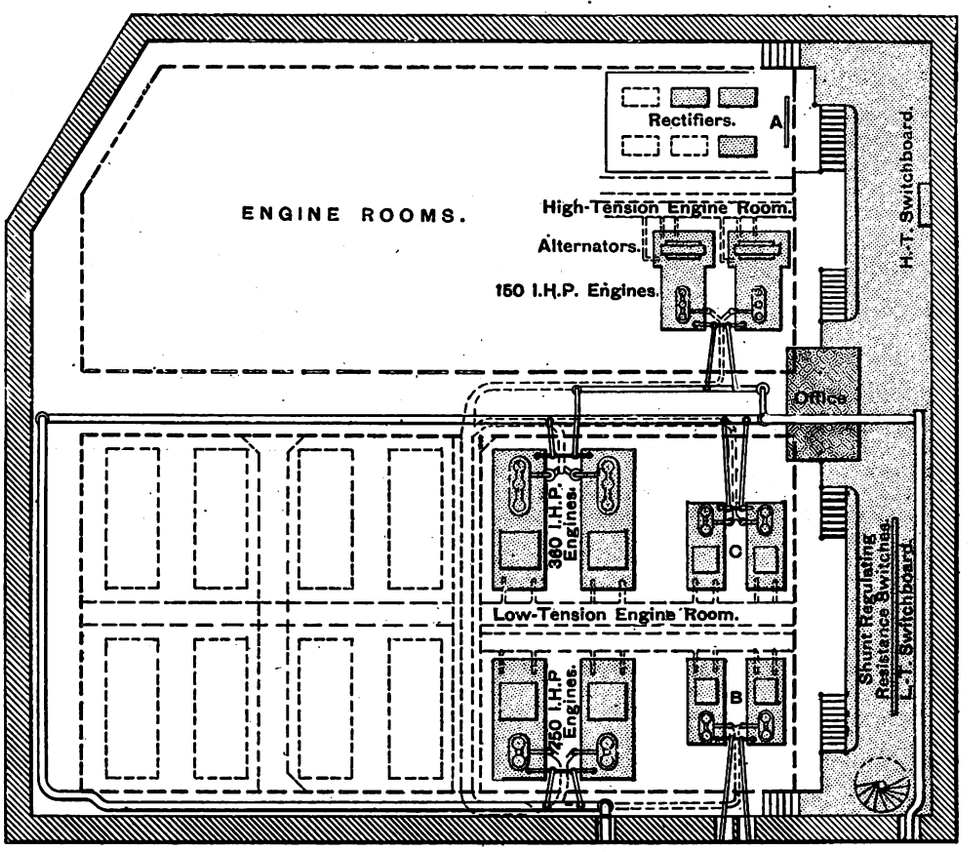

FIG. 3.—Plan of Engine Rooms. A, arc light switchboard; B, balancing machines; C, charging machines.

The steam-piping forms, with part of the boiler-house ring, a complete ring round the low-tension engine room (Figs. 2 and 3), and is connected with the boiler-house ring at two points. The main ring in 8in. internal diameter throughout; the straight lengths are of steel, with thick flanges screwed and brazed on; the tee pieces and valve boxes are of cast iron, and the bends of copper with steel flanges. All bends are of large radius, and no expansion joints are used or required. The engines are erected in pairs, and are connected with the main ring by two long copper bends (Figs. 2 and 3); in the main ring a valve is placed between the branches to the two pipes, with a cross-over pipe and valve at the engines, so arranged that the engines can take their steam from either side of the valve in the main ring. The pipes are slung by long rods from brackets fixed on the walls or columns, so as to allow free movement.

In every section of the main ring are placed two drain-valves, one connected with a drain ring, which is common to half the drains, and is connected with a large steam trap, whereby all condensed water is returned to the feed tank. The other drain valve is connected direct to the exhaust pipe, and is used only on emergency, or when the steam is entirely shut off from that section of the pipes. The separators on all the engines are connected to a second steam trap, which returns the water collected to the feed tank; the drains from the cylinders, &c., are connected to the exhaust pipe. The whole of the steam pipes and valve boxes, as well as the drain pipes up to the steam traps, are covered with non-conducting composition, and special non-conducting covers are fitted on all the flanges; in fact, every attempt has been made to reduce the loss by condensation in the steam pipes, which forms so considerable an item in the losses that occur in central-station work.

All the engines are fitted with cooling pipes in the crank chambers, to which the water is carried in a line of pipe round the engine foundation block, and taken thence to the feed-tank by a second line. Each engine is fitted with a valve on the exhaust; the exhaust steam is led by a copper bend into the main exhaust pipe, which is carried in chases in the engine foundation block and along the void between the block and the walls. The main exhaust pipes are of cast iron, and are led through a Berryman feed heater in the boiler house to the chimney (Figs. 1 and 2). Only one heater is fixed at present, but provision is made for three more when required. From the heater the exhaust steam is carried up to the top of the chimney by a vertical cast-iron pipe 21in. diameter. Valves are provided so that the exhaust steam can be carried direct to the vertical exhaust pipe, without going through the heater.

The whole of the machinery stands on a concrete foundation-block 7½ft. thick (Figs. 2 and 3), which is separate from the foundations of the walls. A void 3ft. wide is left at each side of the block, which is also stopped some distance in front of the switchboard platform, thus forming a large chamber at the west end of the two engine rooms for the connections, &c. An 8-ton travelling crane, running the whole length of the engine block, is provided in each engine room, for convenience in overhauling, &c. These cranes are worked entirely from below by means of ropes.

Leads.—The main leads from the dynamos are drawn through curved wrought-iron pipes let into the concrete, into chases in the centre of the engine foundation-block (Figs. 2 and 3), along which they are carried to the chamber under the switchboard platform. The leads from the field winding of the machines are also carried in the same manner to their regulating resistances, which are placed under the platform; the switches for these resistances are fixed upon the handrail on the platform, in front of the switchboard, the leads from the resistances being brought up through the posts of the handrail.

Switchboard and Conductors.—The switchboard, and the whole of the apparatus for regulating the dynamos and batteries, and for the distribution of the current, are placed on the platform (Figs. 2 and 3) and are directly under the eye of the engineer in charge. The

Digitized by Google

switchboard consists of seven slate panels, each about 7ft. high; and stands 4ft. from the west wall of the engine room, thus allowing ample room to do any work on the connections, &c., at the back. The instruments and gear for regulating the battery are mostly placed on the centre panel, and those for the switching and manipulation of the dynamos and feeders are on the six outer slates; the connections for the positive side of the system are on the left hand, those for the negative on the right, and the middle wire is connected on the centre panel.

(To be concluded).

FRENCH SUBMARINE CABLE ENTERPRISE.

The following article, from the *Journal des Débats* of October 19th, shows in a very striking manner the mixture of state-craft and sanguine financial anticipations underlying the present restlessness of our French friends in the matter of cable enterprise :—

If, as we anticipated in a previous article, it is decided to support the establishment of a French submarine cable network, we cannot do better than follow, in this matter, the example of our rivals across the Channel, and imitate their methods of procedure. The first point which we shall do well to imitate relates to landing rights. In this connection the English Government has always granted the greatest facilities to companies, contenting itself with a simple declaration, and not demanding in return any rights or advantages of a nature likely to hamper the success of the enterprise. With us, on the contrary, it would seem as if we did our best to repulse requests of this kind by an unnecessary display of red tape. Requests for landing rights, even if no special privileges are desired and the responsibility of the State is in no way involved, result in a demand for the most arbitrary guarantees, and the most irksome delays and formalities have to be endured; unjustifiably large deposits of money are exacted, and a tariff is imposed which is complicated by the rules of the inland service and by State control. These are obstacles which it would be advantageous to sweep away, and there need be no difficulty about doing so.

A second, and perhaps more important point, is that of subsidies. It is obvious that such large undertakings as submarine cable enterprises cannot risk the enormous capital required without offering special guarantees to investors. The truth of this principle has long been recognised by the English Government, which has never hesitated to grant cable companies such subsidies as may be necessary to permit them to attain the desired end. The English Government serves out to these companies at present a total sum of 5,105,000fr., and it is owing to this intelligent and generous support of the State that the English companies have been able in so short a period to attain the prosperity they enjoy to-day. It is to be hoped that the French Government will not hesitate to afford to French companies support which is indispensable. It has already given to an English company, the Spanish Submarine Telegraph Company, the sum of 1,700,000fr. for the Teneriffe-St. Louis cable; it grants also to three English companies—the Eastern Extension, the African Direct, and the Eastern—annual subsidies amounting in all to 637,500fr. for the telegraph service between Saigon and Haïphong, that on the West Coast of Africa, and between Obock and Perim. What reason can there be for refusing to French companies the support which is accorded to foreign concerns?

The conclusion to be drawn from these bare statements is very obvious. Up to the present, we have either not known how to act, or we have not desired to act; we have left everything to our rivals. More than this, we have to a certain degree contributed to their success. We must recognise our error, and turn over a new leaf. The French submarine cable network will have no chance of being laid and prospering unless we have the wisdom to suppress administrative obstacles and to grant to national enterprise the support required to enable it to compete with the powerful English companies.

The benefits to be derived from the establishment of a French submarine cable system are manifold. We have pointed out some of them in the course of our investigations. They are of the patriotic order; by this we mean the avoidance of the danger which accrues to our country so long as it depends upon a rival power for telegraphic communication with its colonies. From the commercial point of view, one might say that France can and should become the telegraphic centre and the inevitable telegraphic intermediary in so far as concerns communications exchanged with countries beyond the sea. The geographical situation of France favours this. France is the natural terminus of all the telegraph lines of the Continent of Europe, and it is in France that these lines ought to connect with the submarine cables coming from America. If, as we may reasonably hope, European messages intended for across the sea, and messages from across the sea intended for Europe, go by way of France, not only will this result in the immediate and tangible benefit of acquiring for this country its share of the money paid, but we shall be the first country to receive the financial, commercial, and political news of the entire world. This advantage at the present belongs to England. Thus, thanks to the English submarine cables, London is, so to speak, the central bureau for the news of the entire world. Is it not possible that Paris, better situated than London, should attain this position in good time?

The question arises, are we in a position to construct and lay submarine cables? This question may be answered with an energetic affirmation. We are no longer, to-day, so far as concerns special plant, the tributaries of a foreign country. We possess factories where submarine cables are made in such a good style and so cheaply that we are able to dispense with English assistance. These cables, moreover, have been tested. It was French industry which constructed the cables between Guiana, Martinique and Brazil (3,142 kilometres), which constructed and laid the cable between Marseilles and Oran and Marseilles and Tunis (2,187 kilometres), the cable from Australia to New Caledonia (1,468 kilometres), and the cable from Majunga to Mozambique (700 kilometres). We have consequently ready to hand the necessary industrial appliances and technical knowledge.

Let us therefore make use of them, since the opportunity presents itself, and in this connection let us draw attention to a final point, viz., the amount of new work which the building up of a new network of submarine cables, and the repair of cables already laid, will bring to the national industry. There have been enough complaints of the difficulties which our industry experiences in finding new fields for its activities. Here is one which is a new field opening before it and the size of which may be gauged by a single statement. The submarine telegraph network at present existing has cost one milliard of francs. To-day it is nearly at the end of its tether. Engineers calculate that before 10 years it will be necessary to construct at least 100,000 kilometres of cable to replace lines which have become useless. If we add to this enormous length the new French network which is about to be built up, one may gauge the amount of work which will be brought to French industry. This is a consideration which cannot be neglected, and we submit it to the consideration of those who are responsible for the welfare of the country.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *October 19, 1895.*

The American Street Railway Association.—The Convention of the American Street Railway Association at Montreal during the present week promises to be a very successful one, at least in its commercial aspects. Reports received show that the exhibits of various manufacturers of machinery and material are quite extensive, and that a small army of commercial people are present in the interests of their various houses.

The Thomson-Houston Arc-Light Dynamo Regulator Patent.—The United States Circuit Court of Appeals of Chicago has upheld the decision of the district court, declaring void the Thomson-Houston patent for automatically adjusting brushes upon the commutators of dynamo-electric machines in order to insure a constant current for arc lighting. The Court holds that the mechanism of the regulator does not involve invention, but is merely an adaptation of known methods, to modified or analogous use, no new law or mode of operation being brought into play, and at most only an improved and enlarged action effected. In answer to the argument that if there is no invention in the regulator, why did not someone else make a like improvement, the Court says that such an improvement was made by Maxim at an earlier date.

Death of Mr. Franklin L. Pope.—On Sunday evening of this week Mr. Franklin Leonard Pope was instantly killed by an electric shock at his residence at Great Barrington, Mass. It appears that early in the evening it was found that the incandescent lamps in the house could not be lighted, and Mr. Pope went to the cellar in order to make an examination at the transformer. Very soon after one of the family heard a sound as if caused by a falling body, and upon hurrying to the cellar discovered the body of Mr. Pope near the transformer with life extinct. At the recent Niagara meeting of the American Institute of Electrical Engineers Mr. Pope read a Paper on

Digitized by Google

the Great Barrington plant, which he had just finished reconstructing; the former Edison and Westinghouse machinery was discarded, and two-phased currents brought from a water-power plant some seven or eight miles distant at a voltage of 2,100, the old 1,000-volt converters being used on the alternating circuits, and sub-station converters on the old Edison circuits. Whether the obvious elements of danger introduced by this arrangement was the cause of the fatal shock cannot now be learned. Mr. Franklin Leonard Pope was born in 1840, and at the age of 17 took up telegraphy and was rapidly advanced to positions of responsibility. He was assistant engineer on the exploration and survey in 1864 of the projected Russo-American telegraph line. For the last quarter of a century he has devoted his attention more particularly to inventions, patent practice and technical literature, and has acted as an expert in a number of the most important electrical patent suits. From 1884 until 1890 he was editor of the *Electrical Engineer*, and in 1886 served as president of the American Institute of Electrical Engineers. Mr. Pope possessed the keen intellect, steadiness of purpose and high character typical of the New Englander, and it is noteworthy that he recently removed his residence to his birthplace in the heart of New England, though his business interests were centered in New York City, a half-day's journey distant. No member of the American electrical profession stood higher in the estimation of his *confrères*, both professionally and personally, than Frank Pope, and the news of his untimely death has been received everywhere with expressions of the most extreme regret.

CORRESPONDENCE.

MAGNETIC FORCE AT ANY POINT IN A PLANE CIRCUIT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have succeeded in tracing to its source the discrepancy pointed out by Mr. W. H. Everett (*Electrician*, p. 827) between M. Colard's result and his own. The $\cos\theta$ in M. Colard's formula should be $\cos^2\theta$. His formula for a polygon is correct, and when the polygon becomes a closed curve it reduces to

$$F = \int \frac{ds}{r\rho\cos^2\phi} = \int \frac{d\theta}{\rho\cos^3\phi}.$$

Hence we have the remarkable geometrical proposition that round any closed curve,

$$\int \frac{d\theta}{\rho\cos^3\phi} = \int \frac{d\theta}{r},$$

a result which I believe is new.—Yours, &c.,

J. D. EVERETT.

Derryvolgie-avenue, Belfast, October 22, 1895.

P.S, October 31st.—This agrees with Mr. Russell's result in your last.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Having been absent in vacation, I missed M. Colard's letter in *The Electrician* of September 20th, to which my attention has been directed by Mr. Everett's letter.

M. Colard is quite right to point out that my expression for the force in a rectangular circuit (and, of course, my expression for the force in a triangular circuit in *The Electrician* of September 27th) holds generally for any polygonal circuit, and therefore for any curved circuit. It is very easy to prove that, for any plane circuit, the force at any point, O, in the plane is

$$\int \frac{ds}{\omega\rho},$$

where ds = element of circuit at point P, ρ = radius of curvature at P, and ω is the perpendicular from O on the first pedal of the circuit. This gives at once the expression

$$\int \frac{ds}{r\rho\cos^2\theta}$$

for the force, where, as M. Colard defines, θ is the angle between r and ρ.

There is merely a *clerical error* in M. Colard's expression, with which Mr. Everett finds fault by showing that, in the simple case of a circle, M. Colard's expression leads to an erroneous result.

I need scarcely say, however, that for purposes of actual calculation, Ampére's simple expression (twice the area of the little triangle whose base is ds and vertex O, divided by r^3) is that which is most useful.—Yours, &c.,

GEORGE M. MINCHIN.

Malahide, Englefield-green, Surrey.

MAGNETIC UNITS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Our attention has been called to the claim made on behalf of our colleagues in the United States for rights in a system of names to the magnetic circuit, rights which date antecedent to the German claims of *gauss* and *weber* recently favoured by the Britannic Association. We are desired to make known, however, that this claim has been pegged out already, before the meeting of the Electrical Engineers of the United States; and, had it not been for recent chastisement operations on a western neighbour, which has consumed some of our time, this protest would have been made sooner.

We now have the honour to inform you that three years ago the Institute of Japanese Military Engineers met to consider the question of naming units of all sorts; and after some sittings they issued a comprehensive dictionary of all the units that can ever be wanted, with names attached. They followed the lead of the Britannic Association in selecting C.G.S. units where possible, and in choosing proper names of persons, but they avoided the choice of German or French and still more of Russian names. The fact that they selected largely the names of prominent citizens of their colleagues in the United States must commend the use of this dictionary to that noble country; but neither have they forgotten the British Isles, as the following quotations will show.

The unit of magnetic permeance they named the *Ayrton*, the unit of reluctance the *Perry*, the unit of hysteresis the *Ewing*, and the unit of earth tremor, or vibrations generally, the *Milne*. Further, they named the unit of magnetic induction the *Edison*, the unit of electrostatic flux the *Tesla*, the unit of intensity (of all kinds) the *Silvanus*, and the unit of density the *Forbes*.

But it is needless to quote further from the pages of this comprehensive dictionary, in which few notorious persons are left unrecognised, and which has received the official sanction, not only of H.M. the Mikado and of his powerful Highness the Commander-in-Chief of the Japanese Army, but is countersigned by Admiral Ito. Now know ye, therefore, that any further attempt to wrest these names to other uses or to modify the distribution of distinguished names hereinbefore settled and determined on, is contrary to the spirit of international comity, and if persisted in may be the means of provoking to unlooked-for hostilities.

In the assurance, meanwhile, of goodwill and fraternal amity, we address you these lines on behalf of the Japanese Government and of the Institute of Japanese Military Engineers in conclave assembled, and we subscribe ourselves,—Yours, &c.,

TOROSKI TONO
HARENDRA MUKERJI
L. NISHIGAWA
} *Chief Commissioners.*

LEGAL INTELLIGENCE.

Sabow and Co. v. Barwise.

At the Brompton (London) County Court, on October 24th, the plaintiffs, electrical engineers, of Fulham, sought to recover the sum of £18 in respect of work done in fitting up the electric light in the defendant's shop at Bond-street, London. The plaintiffs became acquainted with two men named Sylvester and Foster, who said they could procure orders for electric lighting work if the plaintiffs would supply the necessary materials and give them a share of the profits, they agreeing to do the practical part of the work. The terms agreed upon were that Sylvester and Foster should be paid 8d. an hour for their work, and should take a share of the profits when the orders were completed. The work was in due course carried out, but when application was made to the defendant for payment it transpired that the money had already been paid to Sylvester. The result was that not only had the two men been paid for their work, but had collected the plaintiff's account.

The defendant said he regarded Sylvester and Foster as principals, and he paid them the account because he never saw the plaintiff in the matter.

Judge STONER said it was pretty clear that the plaintiffs had been very badly treated by their representatives, but he had no alternative but to order a non-suit. If the plaintiff could prove fraud, however, he had the opportunity of prosecuting the men.

The facts in an action, Sabow *v.* Benson, were of a precisely similar character, and, without going into the evidence, his Honour said there must be a non-suit.

South Staffordshire Tramways Company v. Ebbsmith and Wain.

Application was made to the Master of the Rolls and Lords Justices Kay, Lopes, A. L. Smith and Rigby in the first Court of Appeal on the 24th ult., for leave to appeal from an order of Mr. Justice Hawkins refusing to the plaintiffs inspection of the bank books of the defendant, Mr. Ebbsmith, and of the Dickinson Tramways Appliances Company. It was alleged against Mr. Ebbsmith that during the seven years in which he acted as solicitor for the plaintiff Company he sold at exorbitant prices worthless patents to the plaintiff Company without disclosing the fact that the Dickinson Tramway Appliances Company (nominally the vendors of the patents) was really himself; that he sold land to the plaintiff Company, which it was unable to use under its Articles of Association; and that by means of shareholders created by himself meetings of the Company were influenced, and the plaintiffs claimed a return of secret profits alleged to have been made by the defendant while he was in a fiduciary position towards the Company. Application was originally made to Mr. Justice Hawkins for leave to inspect the banking accounts of Mr. Ebbsmith and the Dickinson Company, in order to discover what moneys had been paid to the defendants Ebbsmith and Wain (late Chairman of the plaintiff Company). This leave was refused, and permission was now asked to appeal. After argument their Lordships allowed the appeal.

Pasley v. Bury.

At the County Court, Yeovil, on the 24th ult., an action was heard in which a claim was made for £39. 11s. 6d., the price of a 3 H.P. "Demon" gas engine sold and delivered. There was a counter-claim of £25 for work done to the engine. Plaintiff, who was in business at Sherborne, was an engineer, and the patentee and manufacturer of the "Demon" gas engine. The defendant, who lived at Burnley, Lancs., wished to purchase a gas engine for driving a dynamo, and in November last year wrote ordering an engine of 3 H.P. from Mr. Pasley for £35. 10s. These engines were partly made by Messrs. Carson and Toone, engineers, of Warminster, and to them was entrusted the construction of this particular engine. It was delivered in Burnley in December, and plaintiff claimed that it was thoroughly tested before leaving the works with very satisfactory results. He pointed out that especial regularity was required for electric lighting work, and to secure this it was absolutely necessary to have (1) a flywheel on the dynamo and a second flywheel on the engine, (2) an absolutely firm bed, and (3) proper fixing at the commencement by properly qualified workmen. Mr. Bury did not order a second flywheel, and that would account for the engine being a complete failure for its work. On January 22nd defendant wrote complaining of the engine, and saying that he had made various alterations in its structure. On March 20th plaintiff wrote asking payment. A letter was read showing that defendant consented to pay £38 on the engine being put into proper order. The plaintiff accepted the proposal. Defendant wrote on June 25th offering to pay £30 if the engine was made to run properly, an offer which was refused. The whole difficulty arose, it was contended, from the ignorance of the defendant of the working of gas engines in connection with the electric light. No engine would run electric lights unless it had two flywheels, and the prolonged axle on the engine was made for that purpose.

Mr. WILLIAM CARSON TOONE, engineer, of Warminster, said his firm had made 207 gas engines for the plaintiff. The engine was built and tested under his personal supervision. The test was in every way satisfactory. The fixing and adjustment of the engine was a matter of nicety, and if unskilfully fixed would not work well. The thickness of a bed for the engine should be from 2ft. to 2½ft. Two flywheels should always be used on the engine when used for electric lighting.

Mr. ERNEST COOMBES, engineer, Birmingham, said in 1894 he purchased one of plaintiff's 2 H.P. gas engines for electric lighting purposes. The engine had run very satisfactorily and he had found no defect whatever in it. The engine took three days to properly fix.

The defendant's case was that the onus of proof that the engine did run rested with the plaintiff. As an engineer and millwright he had had 20 years' experience with gas engines. The bed for this engine was laid with 2ft. of concrete and a 7ft. stone, through which bolts ran from below the concrete. Within half an hour of starting the engine the lip of the gas-feed valve wore away, and the governor would not operate, consequently the engine raced. The exhaust valve broke, and the plaintiff sent him another valve. He wrote to the plaintiff that the engine would not go, and he replied, giving him instructions for making alterations, which he followed out. The engine would stop suddenly, and it never ran unless someone was in attendance and looked after it. The engine was then at a Mr. Berry's house, to whom he had sold it to drive a dynamo. He had had no experience with engines like the one in question, where the point of ignition was adjustable, neither had he any experience of the governing arrangement.

Mr. BERRY, hotel proprietor, said the engine was ordered to drive his dynamo. Defendant was at his place for four or five hours daily for weeks attending to the engine; in fact, it never went unless someone stood by it all the time to regulate the gas. The engine was on his premises eight months.

For the plaintiff, it was urged that it had been admitted by the defendant that he had never seen a similar engine to the one in question. He did not understand the working of the governor or the adjustment of the ignition tube. The engine, he submitted, was perfectly able to do the work required, but the whole difficulty arose from the defendant's ignorance.

The JUDGE decided that if the defendant had had the engine properly fixed no difficulty would have arisen. The plaintiff had given the defendant many instructions, but the defendant did not understand the working. He gave judgment for the plaintiff on the claim and counter-claim, with costs on the higher scale.

At the Southampton County Court last week the action brought by the local electric light and power company against Mr. C. Freeman, jeweller, was struck out of the list after having been before the Court since May last. In the meantime the case has been settled on terms agreed between the parties; but it was pointed out that the Company could not, under their Act of Parliament, bring an action at law on disputed accounts for the supply of electric current, but must proceed by arbitration.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

SPECIAL NOTICE.—**The 1895 (thirteenth) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is READY. In addition to the old well-known features of the book, which are brought up to date, a quantity of new and useful matter has been added, rendering the book more than ever indispensable to the Electrical, Engineering, and Allied Trades. Price 7s. 6d., post free 8s. 3d., abroad 9s. The Edition for 1896 is in active preparation, and orders for Advertisements and Subscriptions (5s. 9d. post free, abroad 6s. 6d.) should now be sent in. The usual circulars, &c., will be sent out early in November.**

NEW BOOKS AND EDITIONS.

The following New Books and Editions of "THE ELECTRICIAN" SERIES *can be obtained of the Booksellers or direct from the Publishing Offices:—*

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett *(now ready)*. Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

TENDERS INVITED.—The Corporation of Derby invite tenders for the wiring, fittings, &c., for the completed portion of the Derby Municipal Technical College, at Green Hill. Specifications, &c., can be obtained from Mr. J. E. Stewart (borough electrical engineer), Electric Lighting Station, Derby, on and after Monday next, and tenders must be sent in to Mr. H. F. Gadsby, Town Clerk, by noon on Tuesday, the 12th inst. Some further particulars are given in our advertisement columns.

——— The State Railway Telegraph Department at Saarbrücken, Germany, invite tenders for the supply of 1,500 telegraph poles. Tenders to be in by the 15th inst.

——— The Metropolitan Asylums Board invite tenders for the execution of wiring and other work in connection with the

Digitized by Google

electric light installation at the Brook Hospital and Ambulance Station, Shooter's Hill, S.E., from specification, drawings, &c., prepared by Prof. A. B. W. Kennedy, which can be obtained at the offices of the Board, Norfolk House, Norfolk-street, Strand, W.C. Tenders must be in by 11 a.m. of Monday, the 18th inst. Further particulars are given in our advertisement columns.

ELECTRIC LIGHTING SCHEMES INVITED.—The Battersea Vestry offer premiums of £50, £30 and £15 for the best three schemes, reports, designs and estimates for a system of electric lighting for the parish. Schemes must be delivered to the Vestry Clerk (Mr. W. Marcus Wilkins) by December 12th next.

ELECTRIC METER COMPETITION.—Our advertisement columns contain brief particulars of a prize offered by the Royal Scottish Society (called the Keith prize of £50), for improvements in electric meters for domestic supply. The prize is offered with a view to aid the development of electricity for every-day use. Papers, drawings, &c., must be sent in by May 1st next. Conditions of the competition can be had from the Secretary of the Society, 117, George-street, Edinburgh.

TENDERS ACCEPTED.—The Croydon Town Council received 24 tenders for wiring and fitting up the Town Hall, Courts and Free Library for the electric light. The chief point of interest lies in the great disparity in the figures of the highest and lowest tender, which were £2,685 and £1,124. 15s. respectively. It will also be noticed that the offer of a local firm (Messrs. Wenham and Waters), though not the lowest, has been accepted. Below is a full list of the tenders :—

Wenham and Waters, Croydon (*accepted*)	£1,253	0	0
Hirst and Co., Croydon	2,685	0	0
Cunnington (J. S.) and Co.	2,459	0	0
Smeeton and Page	2,250	0	0
Pettit and Hards	2,070	0	0
Winfields (Limited), Birmingham	1,980	0	0
Rashleigh Phipps and Co.	1,880	0	0
Laing, Wharton and Down	1,861	1	9
Peto and Radford	1,824	0	0
Graham and Biddle	1,776	12	10
Fowler, Lancaster and Co., Birmingham	1,775	0	0
Hands (A. C.) & Co., London, and Page and Miles, Brighton	1,743	5	0
Joel (H. F.) and Co.	1,688	17	0
Hollingam and Saward	1,675	0	0
Edmundsons (Limited)	1,643	0	0
New and Mayne	1,590	0	0
Lund Bros. and Co.	1,548	0	0
Strode and Co.	1,537	0	0
Paterson and Cooper	1,530	10	0
Roger Dawson (Limited)	1,467	10	0
Vaughan and Brown	1,455	0	0
Spagnoletti and Crookes	1,450	0	0
Waring (S. J.) and Co.	1,325	10	0
Binko (H.) and Co.	1,124	15	0

(Remainder of London).

——— The Corporation of Belfast have accepted the tender of the Acme Gas Engine Company for the supply of two direct-coupled gas engines and dynamos for their electricity works. The engines are of 150 I.H P. each.

——— The tender of Messrs. Wm. Harvie and Co., of Glasgow, has been accepted by the Lanark District Council for the electric lighting of the Motherwell Hospital for £2,082. 14s. Prof. A. Jamieson is the consulting engineer for the work.

——— The Burslem Town Council have accepted the tender of Messrs. Crompton and Co. for wiring and fitting up the public baths for the electric light for the sum of £213 ; four arcs and 43 16 c.p. incandescents will be used.

——— The tender of Messrs. Veale and Co., of St. Austell, has been accepted for the installation of the electric light at the factory of the British and Colonial Explosives Company ; 107 incandescents will be used, and the contractors have guaranteed that the work shall be completed in eight weeks.

——— The Metropolitan Asylums Board have accepted the tender of the Callender Company for supplying and laying electric light cables at the hospital ships for £125.

POSTPONEMENT OF SALE.—Messrs. Wheatley Kirk, Price and Goulty give notice that the disposal of the business of Poole and White (in liquidation) which has been announced to take place at the Mart, in one lot, at an early date, has been postponed for the present.

CHANGES OF ADDRESS.—Messrs. E. P. Allam and Co. announce that, owing to increase of business, larger offices and showrooms for electric light fittings have been taken at 14, Hatton-garden, Holborn, London, E.C., to which address all communications for the firm should be directed.

——— Messrs. King, Mendham and Co. have found their present premises in Narrow Wine-street, Bristol, inadequate for carrying on their business, and have taken larger premises at 10, Victoria-street, where extensive alterations are being made to adapt them to the requirements of a manufacturing business.

BUSINESS FOR SALE.—Electrical engineers can obtain particulars from Messrs. Wheatley Kirk, Price and Goulty of a small electrical business for disposal in London, which would well suit a person with a small connection to add to the present business.

APPOINTMENT.—The Electricity Supply Committee of the Lancaster Corporation have appointed Mr. C. M. Johnson (assistant electrician under Mr. A. S. Barnard) to be electrician at the electricity works, vice Mr. Barnard. The appointment is on probation for a period of three months, and the salary is at the rate of £100 per annum! Mr. Johnston is "to perform such duties as the Committee may from time to time determine, and to act under the instructions of the borough surveyor."

APPOINTMENT VACANT.—The Ealing District Council invite applications for the position of chief electrical engineer for their electricity works. Applications must be sent in to the Clerk (Mr. Wm. Ruston) not later than 3 p.m. on Wednesday, the 6th instant. Some further particulars are given in our advertisement columns.

——— The professorship of applied mathematics and experimental physics in the South African College, Cape Town, will be vacant at the end of 1895. The salary of this appointment is £500 per annum, with a possible increase of £100. Applications must be sent in, addressed to "Cape," care of *Nature*, 29, Bedford-street, Strand, W.C.

——— The appointment of Head Master of the Science, Technological and Commercial Department of the Plymouth Technical Schools is vacant. The salary is £300 per annum. Particulars can be obtained of the Secretary, Mr. T. W. Byfield, and applications must be sent in by the 15th inst.

DYNAMO BRUSHES.—The Boudreaux Dynamo Brush Company of St. Martin's House, Gresham-street, E.C., forward a sample of a new anti-friction gauze dynamo brush, which is made from the same metal alloy as the well-known Boudreaux foliated brush, and possesses, it is claimed, the same advantages, with the exception that the duration of the brush is not quite as good. The gauze brush is, however, 25 per cent. cheaper, owing to the fact that the gauze pattern can be produced at less cost than the rolled metal type. The result of proceedings taken by M. Boudreaux against infringement of his patents has, it is stated, resulted in his rights being maintained.

COMPAGNIE FRANÇAISE DES CABLES TÉLÉGRAPHIQUES. — This Company announce that their New York address is now 44, Broad-street.

AGENCIES.—Messrs. Conze and Simon, of 52, Queen Victoria-street, E.C., have been appointed sole agents for the Cologne Accumulator Works, and are prepared to give prices and particulars regarding this firm's type of accumulator. These cells have been largely used all over the Continent for many years past, and it is claimed that their efficiency and durability have been abundantly proved.

——— The Stanton Iron Works Company inform us that they have appointed Messrs. Beck and Co. (Limited), Great Suffolk-street, Southwark, S.E., as their representatives for London and the South and West of England, vice Mr. Frederick Davis, who has retired.

THE "ENGINEERING MAGAZINE."—The November issue of this magazine fully maintains its high standard of excellence both as regards the number and variety of the subjects dealt with and its numerous illustrations. The articles in the number include:—"The Currency Problem and its Solution," by A. Mills ; "Taxation in the United States," by E. Atkinson ; "Contemporary English Architects and their Work," by W. Heathcote Statham ; "The Prevailing Scarcity of Skilled Mechanics," by A. E. Outerbridge, jun. ; "The Distribution of Power in Collieries," by Ll. B. Atkinson ; "Transatlantic Steamships of 1856 to 1880," by S. W. Stanton; "Will a Bridge across the Hudson River Pay ?" by Gustav Lindenthal ; "The Limits of Electric Power Transmission," by A. D. Adams ; "The Colorado Springs Waterworks," by A. Lakes ; and "The Massachusetts Railroad Commission," by W. A. Crafts. The usual Exhaustive Review of the industrial Press is also given. This number, as well as all the back numbers, may be obtained at the offices of the European Edition, 1, 2 and 3, Salisbury-court, Fleet-street, London, E.C. A complete index to the main articles in the magazine from the commencement in April, 1891, is now ready, and will be forwarded post free on request.

ALLEGED FALSE PRETENCES.—Before Mr. de Rutzen, at the Westminster Police Court on Monday last, a Frenchman named Jean Molas, calling himself an electrician, was charged with obtaining £250 by false pretences. Defendant pleaded not guilty and was remanded for a week.

ANGORA (TERCEIRA, AZORES).—A proposal for lighting this, originally the capital town of the Azores group, by electricity, has

Digitized by Google

been adopted, an influential committee of citizens having been formed to take the steps necessary to the formation of a local company. Señor Chassereux, cheese and butter factor, takes a leading part in the movement. There is no gas on the island, and the prospects of electric lighting are considered good. Water power will probably be utilised.

ASYLUM LIGHTING.—The work in connection with the extensive alterations and additions to the Murthly Asylum, Perth, is now approaching completion. The electric light has been installed by Messrs Anderson and Munro, of Glasgow, to the specification of Mr. W. A. Bryson.

BEDFORD.—In order to dispose of certain misstatements that have been made in this town as to the financial position of the Corporation's Electric Lighting undertaking, the Electric Light Committee have furnished the local Press with a copy of a report presented by the Clerk of the Urban Sanitary Authority (Mr. T. S. Porter) upon this subject. This report is as under :—

"October 23, 1895.

"The annual amount payable in respect of interest and repayment is as follows :—

First annual instalment of principal			£480	
One year's interest on £12,000			390	
			—£370	
£370 per annum equals about	£16	14	7	per week.
Fuel, &c. (£7. 8s.), wages, &c. (£8. 8s.), salaries, &c. (£3), equals	18	16	0	,, ,,
Total cost	£35	10	7	
Actual gross earnings for week ended Oct. 2',	38	5	0	=+£2 14s. 5d.

"A number of premises are waiting to be wired, and applications have been received from many ratepayers to have their houses connected ; but no current can be supplied to new customers until the works of extension are completed."

BLACKWALL TUNNEL.—The contractors of this important undertaking on Wednesday invited some hundreds of visitors to an inspection of the subaqueous communication which has been successfully established between the Poplar and Greenwich shores of the river Thames. A large number of engineering celebrities were present and expressed their admiration of the excellence of the work. The whole tunnel was lighted from end to end by incandescent lamps. The tunnel is to be open for public inspection tomorrow (Saturday) and Sunday between 10 a.m. and 10 p.m. at the small charge of 3d. per admission. The work has been completed without serious accident or loss of life.

BRAY.—At the last meeting of the Town Commissioners it was decided to apply for a Provisional Electric Lighting Order. Our readers will remember that the Commissioners recently obtained power to purchase the existing works from the liquidator of J. E. H. Gordon and Co. (Limited) for the sum of £3,060.

BRIGHTON.—At their meeting yesterday the Corporation discussed a long report on the subject of the Brighton and Rottingdean Seashore Electric Railway, prepared by their surveyor, Mr. F. J. C. May, who recommends that the Rottingdean and Seashore Electric Railway Company be asked to complete the line outside the borough and make certain experiments thereon in order to enable the Corporation to judge "whether the project is likely to be beneficial or prejudicial to the interests of Brighton." This course is recommended owing to certain modifications of the original design of the cars, which the Company claim has been necessitated by the regulations made by the Board of Trade. With respect to the suggestion that the Company should first complete their line outside the borough, thereby entailing the stoppage of the works within the borough area, Mr. R. St. George Moore, the Company's engineer, points out that this would render the completion of the line within the period allowed by the Company's Act of Parliament impossible. Mr. Moore insists that the Company has done everything possible to meet the wishes of the Corporation officials.

BURNLEY.—The Town Council have received the formal sanction of the Local Government Board for borrowing an additional sum of £5,500 for electric lighting purposes. The borough electrical engineer (Mr. F. Thursfield) has been authorised to attend the forthcoming conference on the new regulations proposed to be made by the Board of Trade with regard to the supply of electric current.

CALCUTTA.—The Commissioners of this city are giving serious attention to the electric lighting question. Fresh tenders are called for the lighting of Harrison-road, and it is considered probable that further extensions will shortly be decided upon. It would appear that the Commissioners have expressed an intention of using overhead cables, but this proposal meets with strong objections from the Indian Press.

CARDIFF.—Mr. W. J. Bird Clerke held a Local Government Board inquiry last week into the application of the Town Council to borrow £12,885 for electric lighting purposes. The Mayor stated that the compulsory area was now lighted electrically, and the present loan would be devoted to defraying the excess of expenditure over capital already borrowed, to extending the electric light mains, and to the erection of a testing station. Mr. S. F. Walker opposed the application on general and particular grounds, and especially because the present works were not paying and, he asserted, could not pay, and that any further increase of the outlay under the present arrangements would add to the deficit. He asserted that at the present time they were losing £6,000 a year, including interest on the money borrowed. In the course of the discussion which followed, Mr. W. Harpur (the borough engineer) stated that the increased demand for electric current certainly justified the additional expenditure. They had applications during the last two months for an average of 1,000 lamps per month, and the demand exceeded the Council's most sanguine expectations. In fact, they would shortly have to consider the question of enlarging the generating station. In the end Mr. Walker appeared to a small extent satisfied with the answers vouchsafed to his multitudinous and not always relevant questions, Mr. Harpur stating that Mr. Walker's assertions were, in the bulk, "absolutely wrong," and that, in one case especially, the Corporation were having work done for between £600 and £700, against £1,000, the tender of Mr. Walker's own firm. At the same time, it is only fair to Mr. Walker to mention that, according to the report in the local Press, "his firm did not want the contract."—The Corporation have decided to remove the rectifiers from the Town Hall to the Central Station at Canton, at an estimated cost of £700 or £750, as such removal will effect a saving in wages of about £175 per annum. Applications for installations are coming in in a very satisfactory manner, and the Mayor has expressed an opinion that twelve months hence the electric light at Cardiff would prove not only a public boon, but a paying concern.

CARDIFF EXHIBITION.—The forthcoming Commercial Exhibition at Cardiff is to be rendered additionally attractive by the construction of a model coal mine, occupying a space of 110 yards in length and 40 yards in width. The Executive Council, at their meeting last week, advanced arrangements considerably, and the success of the Exhibition is practically assured. The Corporation have been asked to provide the current for lighting the Exhibition, but the suggestion which finds most favour is that the Executive Committee should provide the installation, and that the Corporation should be approached to purchase the plant at reduced rates after the Exhibition is over. A committee has been appointed to consider the matter.

CHURCH LIGHTING.—The electric light has just been introduced into St. Andrew's Church, Southport.——All Saints' Church, Norfolk-square, London, W., is to be lighted electrically.

CORK.—The second report of the Electric Lighting Committee has just been presented to the City Council. The Committee report that in accordance with the Council's authority they had engaged Mr. T. W. Smith, of Manchester, to advise them with reference to the proposed application for a Provisional Order. Mr. Smith recently made an inspection of the city, and, in a report, states that the city is eminently suitable for the erection of a remunerative electricity station. The Corporation already possess a suitable site near the Municipal Buildings, and taking this fact into consideration, the cost of the necessary building, plant, machinery, &c., for public lighting would be £8,000, and the annual up-keep charges, interest, &c., would be about £2,000. If, however, the Council wished to adopt a more comprehensive scheme, and undertake to supply current for private lighting, then the cost would be about £20,000, and the annual up-keep would be £3,000. If the latter scheme were adopted it was estimated that the revenue from the sale of current for private lighting would £3,125 per annum. This would leave a net profit of £125, besides lighting the main streets of the city free of cost. The Committee might also reasonably expect a certain demand for electric current in the day time for motive power purposes. The Committee have considered Mr. Smith's report, and they have come to the conclusion to recommend the Council to at once apply for a Provisional Order. The Committee further recommend that the applications of the Cork Gas Consumers' Company, the Cork Electric Light and Power Company and the Irish Electrical Supply Company for Provisional Orders be opposed. These recommendations were, after some discussion, adopted at the last meeting of the County Council.

COVENTRY.—The work of constructing and equipping the Coventry electric tramways is now practically complete, and it is anticipated that the cars will be running in about a fortnight's time. The line has been constructed for the overhead wire system, and the work of equipping the generating station at Foleshill has been carried out by the General Tramways Company.

DERBY.—The Chairman of the Provisional Committee for the promotion of the light (electric) railway from Derby to Ashbourne has issued a circular to the promoters, in which it is stated that

"the scheme has been enthusiastically received by the Ashbourne farmers and several gentlemen, who, thinking that it would benefit the agricultural community, and promote local interests generally, have promised to subscribe towards the expenses of obtaining Parliamentary powers, it being understood that in the event of the failure of the scheme any money beyond what is required for actual out-of-pocket expenses shall

Digitized by Google

be returned to the subscribers proportionately; but if the Bill is passed into law, and a company incorporated thereunder, £1 shares in such company shall be allotted to each subscriber for every £1 subscribed. Further support, however, is needed to justify the Committee in proceeding with the application for the Bill."

DOCK LIGHTING.—The work of installing the electric light at the Tyne Dock for the North-Eastern Railway Company has just been completed. About 60 Crompton-Pochin arcs are used. The lamps are fixed on poles at a height of 30ft. from the ground, except on the coal jetties and at the dock entrances, where the height of the poles has been reduced to 23ft. The generating plant consists of three compound-wound Crompton dynamos driven by Marshall engines. The whole of the work has been carried out by Messrs. Crompton and Co.

EDINBURGH.—At the meeting of the Town Council on Tuesday last the Lord Provost's Committee recommended the cabling of various sections of the tramways as per plan submitted. The Lord Provost pointed out that the step proposed to be taken was a very important one. They had had numerous suggestions as to the adoption of electricity as a motive power, but they had never been approached by electrical engineers on the matter. That, he took it, showed that electricity was not regarded as a suitable motive power for Edinburgh. To the best of their knowledge the cabling system was the most suitable. The recommendation of the Committee was agreed to. Negotiations are in progress for the acquisition of the tramway lines from Waterloo-place to Jock's Lodge. The Edinburgh Street Tramways Company claim, it is understood, over £20,000 for the lines about to be acquired by the Council, but the actual sum to be paid is to be settled by arbitration. The Cleaning and Lighting Committee are to consider and report upon the advisability of extending the electric light mains from Waterloo-place to Abbey Hill.——It is stated that the Caledonian Railway Company, owing to complaints from the inhabitants in the neighbourhood of their Morrison-street depôt concerning the spray from the Lucigen oil lights, have decided to remove them and to substitute electric arc lights. The Company will at the same time instal the electric light at their goods yard in Lothian-road.

ELECTRIC PUMPING IN COLLIERIES.—An electric pumping plant has recently been installed in the Friedlicher Nachbar Colliery, Linden (Westphalia), Germany, which is capable of raising 1¼ cubic metres of water per minute to a height of 360ft. The generating plant is situated above ground, and includes a 75 H.P. steam engine, and a dynamo giving 80 amperes at 600 volts, while underground there is a 60 H.P. electric motor connected up to a triple-acting pump.

ELECTRIC TRACTION IN SOUTH AFRICA.—The Port Elizabeth tramways have been purchased by Mr. Henry Butters, of Cape Town, one of the conditions of the transfer being the introduction of a system of electric traction.

EMPIRE OF INDIA EXHIBITION LIGHTING.—The electric lighting of this Exhibition is uniformly described in the public Press as a most marked success. Certainly Messrs. Davey, Paxman and Co. are to be congratulated on the complete steadiness of the light, and Mr. Guy C. Fricker, who is in charge of the installation, is to be complimented upon the care bestowed on the installation and its efficient working. About 260 arcs and over 8,000 incandescents are used in the lighting, which has given the utmost satisfaction to the Exhibition authorities. The load is of an extremely varying character, the theatre frequently putting on or taking off nearly 100 H.P. repeatedly during the evening performance.

EVANTON (ROSS-SHIRE).—At the last meeting of the Parish Council a scheme for lighting the village of Evanton by electricity was brought forward by Mr. R. Macintyre, a member of the Council. Mr. Macintyre read a report as to cost., &c., which had been prepared by Mr. R. F. Yorke, electrical engineer, of Glasgow. It is proposed to utilise water power, and the initial expenditure would only amount to £320. The matter is to be further considered.

EXETER.—At the meeting of the City Council on Wednesday last a communication was read from the Board of Trade as to the conditions under which they would be prepared to consider the revocation of the Exeter Electric Light Company's Provisional Order, in view of the purchase of that Company's undertaking by the Council. The letter was referred to the Electric Lighting Committee for consideration and report.

FERMOY (IRELAND).—A special meeting of the Town Commissioners was held last week for the purpose of considering the report of their consulting engineer (Mr. F. J. Warden Stevens) on the question of lighting the town electrically. Mr. Stevens stated that he had surveyed the district and had taken into account the water power which would be at their disposal, and he had come to the conclusion that the Commissioners would experience no difficulty in establishing electricity works. An electric lighting scheme would certainly be far better and cheaper than gas, and he advised the Commissioners to apply for a Provisional Order. The Commissioners intend to advertise for schemes.

FULHAM (LONDON, S.W.).—A special meeting of the Electric Lighting Committee of the Vestry will be held on Thursday next for the purpose of selecting an electrical engineer to assist them in formulating an electric lighting scheme for the Parish.

GLOUCESTER.—A special meeting of the City Council will be held on the 12th instant. for the purpose of considering the advisability of applying for a Provisional Order. Recently a deputation, consisting of Messrs. George White (Managing Director of the Bristol and Gloucester Tramways Company), Kincaid and Devonshire, attended before a joint meeting of the Finance and Streets Committees of the Council, in order to explain the views of the Tramways Company as to the adoption of a combined electric lighting and traction scheme by the Council, and the lines on which the two bodies might co-operate in carrying it out. The consideration of the matter was adjourned in order that further information might be obtained prior to the special meeting of the Council.

GLOW LAMPS FOR THE BATTLE-FIELD.—It is stated to have been decided by the French military authorities to provide glow lamps with pocket batteries for the use of the members of the Ambulance Corps in place of the old-fashioned lanterns. The advantages of electric glow lamps for use on the field after a battle will be found fully set out in the *Daily Telegraph's* own inimitable style in the issue of that journal for October 26th.

HOSPITAL LIGHTING.—The newly-erected Royal Hospital for Sick Children at Edinburgh, which is to be formally opened by the Princess Beatrice this afternoon, is lighted throughout electrically.

INDUSTRIAL EXHIBITION OF BERLIN.—The preparations for the opening of this Exhibition next year are proceeding satisfactorily. £25,000 have been voted by the Committee of Works for the buildings and general organisation, and other large sums have been received by the organisers of the Exhibition. It is stated that no less than £170,000 is to be spent in street improvements in order to provide ready access to the Exhibition buildings. Three new electric railways are to be put down at an estimated cost of about £50,000, and a similar sum is to be spent upon the extension of the metropolitan and Circular railway in the city. A full success for the enterprise is anticipated, and from reports to hand it would appear that the Empire City is bestirring itself to secure this success. Side shows will include Old Berlin, Cairo, a panorama of the Alps, and other similar spectacles.

KETTERING.—The Electric Light Committee have been for some time past collecting information as to the cost of lighting a part of this town by electricity. The Committee have just presented their report to the Council, and they recommend that application be at once made for a Provisional Order. The Committee estimate that the cost of a scheme for lighting the proposed compulsory area, including the supply of current for an equivalent of 2,500 8 c.p. incandescents, would be about £9,500.

KINGSTON-ON-THAMES.—Some time ago the Town Council wrote to the Maldens and Coombe District Council on the question of the introduction of the electric light, but the District Council replied that they were of opinion that the matter was not yet ripe for consideration. At the last meeting of the Kingston Town Council letters from some ratepayers in the Malden District were read protesting against the decision of their Council and asking if any arrangement could be made by which they could obtain electric current. The Native Guano Company also wrote stating that they were paying £71. 15s. 8d. per annum for gas, and that they were quite ready to spend a similar sum for lighting their works electrically. After discussion it was left to the chairman of the Electric Lighting Committee, the town clerk and the borough electrical engineer to make the best possible arrangement.

LECTURES.—Prof. J. A. Fleming delivered the second of a series of popular science lectures at the Town Hall, Portsmouth, last week, on the subject of "Electric Currents and Magnetism." The lecture was illustrated by experiments and gave great pleasure to a large audience.

LEEDS.—The Leeds Tramways Committee have decided to recommend that Dr. John Hopkinson be called in to advise them as to an experiment in electric traction being made. The Committee suggest that the overhead wires in Roundhay should be continued up to the Canal Gardens, the wires to be suspended from brackets placed upon poles in the centre of the road. It is also proposed to extend the wires in a similar manner along North-street and down Briggate to Boar-lane. The Committee further suggest the laying of a conduit from Boar-lane to the Yorkshire Bank, and that from this latter point the overhead wires should be continued to Kirkstall. If possible, central poles will be used along the Wellington-road. The Committee think that the experiment would afford a thorough test of the merits of electric traction, and also of the practicability of the overhead and conduit systems being worked in conjunction. The Committee's recommendations were adopted at yesterday's meeting of the Town Council.

LEICESTER.—At the meeting of the Town Council on Tuesday Mr. Alderman Lennard, in moving the adoption of the Gas and Electric Lighting Committee's report, referred to a petition which had been presented from local electrical engineers and contractors regarding the course adopted by the Committee in supplying electric light fittings, &c. The Committee were, however, unable to recommend the Council to make any alteration in the present practice of the fittings department of their electric lighting undertaking. He claimed that the electrical department were only carrying out the policy adopted in the gas department for the past 12 or 13 years. He complained of anonymous letters in the local Press regarding the work of the department, in some of which statements quite at variance with the truth were permitted to appear. It was untrue to assert that the Committee had transgressed in any way their own rules by the substitution of finer gauges of wire than other contractors were allowed to use. He had investigated this point and had satisfied himself that there was no justification for such a statement. These and other similar statements were false. He was not an advocate for indiscriminate manufacture and trading by the Corporation, but where large interests like the gas and water departments were concerned, in which there was something like a million and a quarter of the ratepayers' money involved, and where, in fact, the success of the department to a very large extent depended upon the fittings which were used for consuming the commodities supplied, he held it to be the duty of the Corporation to keep that auxiliary work in its own hands. It was good for the community at large. They had never made a loss in connection with the supply of these fittings, which was proof that they had not cut prices. If the department had been a loss, then the local tradesmen would have a right to complain, as it would be an indication that work was being done at less than fair prices. Councillor Marshall did not complain so much of the Department doing this fitting work, but he took exception to the touting for business. He understood that the gas fitting department simply supplied fittings at request, and if this policy were carried out by the electrical department he thought no member of the Council could object to it. Councillor Billings denied that any undue canvassing had taken place. What had happened was that in obtaining customers for the supply of current, orders had been given to their canvassers for fittings. He believed the department was doing right in supplying the fittings and in that way contributing to the success of the Corporation's installations. Alderman Coleman, a member of the Electric Lighting Committee, considered that when they had manufactured the gas or electric current and had brought it to the consumers' door, their connections with the supply ended. Councillor Biggs complained of the circulars that had been issued by the electrical department, and considered this method of canvassing unfair. Alderman Lennard, in reply to the remarks of councillors, said that the real ground of complaint seemed to be that the representatives of the Corporation had canvassed and had to that extent departed from the old practice, but the fact was that at the time when canvassing for customers for electric current was going on, conversations with the canvassers naturally ensued, and the subject of the necessary fittings was then entered into and orders given to the Corporation employés. The report of the committee was ultimately approved.

LLANDUDNO.—The Llandudno Electric Lighting Company have decided to ask four electrical engineers to state their fees for preparing an exhaustive report on the electric lighting of the town. The District Council have already obtained a Provisional Order.

LLANELLY.—The Borough Council have offered to sell their Provisional Order to Messrs. J. C. Howell (Limited) for £200.

LONDON COUNTY COUNCIL.—At the meeting of the Council on Tuesday last the engineer (Mr. A. R. Binnie) was empowered to engage temporary assistance, in order to satisfactorily cope with the very large amount of work at present devolving on the electrical staff of his department. It was pointed out that this work has now become very heavy, owing to the very considerable extension of electric lighting work throughout the area under the Council's jurisdiction, especially in connection with inspections of electric light installations at theatres and music halls, the examination of proposals for loans to vestries and district boards for electric lighting purposes, and the lighting of the Blackwall Tunnel. It was reported by the Finance Committee that the Treasury had sanctioned the period of 53 years for the repayment of the loan of £5,150 to the Vestry of Islington for the purchase of land for extending their electric lighting station. The Technical Education Board reported that three new workshops had been erected at the Battersea Polytechnic, which would be used for instruction in, amongst other subjects, electrical engineering. They further stated that the South-West London Polytechnic, at Chelsea, erected at the cost of £25,000, had been opened, and that the building was lighted throughout by the electric light.

MANCHESTER.—The Town Council intend to apply for an extension of their present electric lighting area, but it is proposed to make only one portion of the work in connection with the extended area compulsory.

METROPOLITAN ASYLUMS BOARD.—At the meeting of the Board on Saturday last a report was presented by the Ambulance Committee on the subject of the wiring of the Brook Ambulance station and recommending that this work be given out in conjunction with the wiring of the Brook Hospital. It will be seen from our advertisement columns that the recommendation of the Ambulance Committee has been adopted. On the recommendation of the Brook Hospital Committee it was decided to approve the suggestion made by Prof. Kennedy, in preparing plans and specifications for the installation of the electric lighting of the hospital, to invite tenders for engines, dynamos, switchboards and batteries from a select list of firms. The wiring, &c., to be put to public tender. The following is the list of firms who are to be invited to send in tenders:—Messrs. Siemens Bros., Crompton and Co., Johnson and Phillips, J. H. Holmes and Co., Thomas Parker (Limited), British Thomson-Houston, W. H. Allen, Son and Co., Mather and Platt, Davey, Paxman and Co., Robey and Co., Marshall, Sons and Co., and the Electric Construction Company.

NEWCASTLE-ON-TYNE.—At the special meeting of the City Council on Monday the discussion on the report of the Town Improvement Committee was resumed. The principal features of the report are the recommendations that the Council should expend £127,000 in the construction of cable tramways to Byker and Scotswood, Westgate-hill and Arthur's-hill and Elswick-lane, worked from a power station proposed to be erected in Bath-lane. The Committeealso propose to grant a lease for 21 years to the present Tramway Company, whose lease of the existing tramways will expire in about four years. The conditions of the proposed lease were set out in our last issue, while the local objections to the report are: (1) the granting of a lease for so long a period as 21 years; (2) the proposal to treat only with the existing Company—it being contended that the right to work the tramways should be open for tender; (3) the non-inclusion of the Stanhope-street district in the scheme, and (4) it is contended that the Corporation should itself take powers to work the lines. A long debate ensued, in the course of which several speakers advocated the adoption of electric traction, but the Council eventually approved the report. It was, however, agreed that in the Council's Parliamentary Bill powers be sought to work the other sections of the lines by electricity or other motive power.

OLDHAM.—The Local Government Board have sanctioned the borrowing of a further sum of £15,000 for electric lighting purposes.

PROVISIONAL ORDER.—The Urban District Council of Cowes, Isle of Wight, gives the usual official notice of its intention to apply to the Board of Trade on or before December 21st next for a Provisional Order under the Electric Lighting Acts 1882 and 1888.

RATHMINES (DUBLIN).—At a special meeting of the Improvement Commissioners of Rathmines and Rathgar on Monday last it was decided to apply to the Board of Trade for a Provisional Order.

REDUCTION IN TELEGRAPH RATES.—The Direct United States Cable Company and the Western Union Telegraph Company announce a reduction of rates to Winona (Min.) U.S.A., from 1s. 5d. to 1s. 3d. per word, the reduction to come into force this day.

REUTER'S AGENCY.—The *City Press* (London) of October 30th contains an interesting account of the history of this undertaking, the occasion being the celebration of the golden wedding of Baron and Baroness de Reuter. The first principal office of the Agency was opened at the Royal Exchange in October, 1851, de Reuter, with Mr. F. J. Griffiths (who is still with the firm), being concerned in the early work of the Agency.

SERIOUS GAS EXPLOSION.—An alarming gas explosion occurred on Tuesday evening last in a densely-populated section of the Strand (London, W.C.) district. For some time past a leakage had been noticed, which finally filled the basement of a small house, and ultimately resulted in a disastrous explosion, causing the loss of a fireman's life and very serious injury to over thirty persons, in addition to considerable destruction of surrounding property. If this disaster had been due to electricity what would the gas journals not have said?

SMOKING CONCERT.—A smoking concert of the City Electric Athletic Club is to be held at the Mason's Hall Tavern, Basinghall-street, London, E.C., on Thursday, the 14th inst., for which an excellent programme has been prepared.

SOUTHAMPTON.—The Southampton Harbour Board, at their meeting on Tuesday, considered the report of their Electric Lighting Committee on the question of putting down an independent generating plant at a cost of £5,500. The Board have hitherto been taking current from the Southampton Electric Light and Power Company, and they proposed to erect an electricity station on the Town Quay, near the Harbour Offices. In reply to a question, the Town Clerk produced figures showing a saving in favour of the Corporation's electric supply station of £172 per annum.

Digitized by Google

SOUTHPORT.—A long discussion on the tramways question arose at the meeting of the Town Council on Tuesday. Negotiations for the purchase of the undertaking of the Southport Tramways Company have been in progress for the past three years, and the Council, despairing of coming to an amicable arrangement on the subject, have now determined to petition the Board of Trade to fix a price at which they could take over the lines. It was, however, agreed to give the Tramway Company a month's grace, and the Tramways Committee have been empowered to retain expert witnesses on behalf of the Council. About three-quarters of a mile of the lines run beyond the borough boundary, and a question of interest outside the boundary arises with the adjacent local authority.

STAFFORD.—It has been decided to amalgamate the Gas and Electricity Committees of the Town Council. At the sitting of the Council on Wednesday last it was agreed, on the recommendation of the Committee, in order to reduce the cost of raising steam for driving the machinery in the gas and electricity departments, to lay down a steam main from the boiler houses in the two departments at a cost of about £200, it being stated that this arrangement would enable the electricity department to do with two stokers. It was also decided to extend the electric lighting mains as far as St. Paul's Church, Lichfield-road, at a cost of about £250.

STAPLETON.—The District Council have appointed a Committee to consider the question of lighting their district electrically.

STEALING AND RECEIVING.—Before Alderman Sir Stuart Knill, on Wednesday, at the Mansion House Police Court, two men, James Murray (a clerk), and George Fowler (an agent), were charged with stealing and receiving respectively during the last three months 365 incandescent electric lamps (valued at £22. 16s. 3d.) belonging to the General Electric Company, of Queen Victoria-street, E.C. On the 23rd ult. the Manager of the Company (Mr. Wilson) went to Farringdon-road, where the prisoner Fowler was offering for sale from a barrow some incandescent lamps bearing the Company's trade mark. Fowler said he had bought them from a man, who was subsequently identified as the prisoner Murray, at 3s. a dozen. Murray was a warehouse clerk in the Company's service, and he admitted taking the lamps from the warehouse a few at a time, and selling them to Fowler, who at first paid him 3s. and afterwards 2s. a dozen for them. It was stated that the lamps were worth 1s. 3d. each. The prisoners were committed for trial, Fowler being admitted to bail.

TELEPHONIC COMMUNICATION IN ARGENTINA.—The United River Plate Telephone Company are extending their system to the town of San Martin.

TELEPHONES FOR TELEGRAPH WORK.—In our report of the proceedings at the meeting of the shareholders of the Amazon Telegraph Company (Limited) it will be seen that the Chairman, Mr. W. S. Andrews, referred to the decision of the Directors to introduce the telephone with the object of establishing communication over the smaller cables owned by the Company, which would enable these lines to be worked without the employment of skilled labour. The telephones to be used are those manufactured by the Single Wire Multiple Telephone Signal Company, of London, under the patents of Collier and Brown, which were a short time back described in these columns, and which have recently been tested by the well-known firm of Messrs. Clarke, Ford and Taylor, engineers to the Amazon Company, and have been found, we understand, specially adapted for this class of work.

THEATRE LIGHTING.—Messrs. Vaughan and Brown (Limited), of Hatton Garden, E.C., have very successfully lighted the Lyric Theatre, at Bath, and the Empire Theatre, at Bristol. The work done by the firm includes electric lighting, gas fitting, and hot water work.——The Prince's Theatre, Bristol, is now lighted electrically. The work of wiring has been carried out by a local firm (Messrs F. W. Ball and Co.), and current is being obtained from the Corporation mains.

"THE AUTOCAR."—A new journal is to be published in London under the above title, in the interests, as its name denotes, of automobility. It has been suggested that some new and convenient name should be established by which the new automatic or motor-propelled horseless carriage may be known, and "Autocar" is the result of careful selection. Messrs. Iliffe and Son are the publishers of the new journal.

THE BERNE VOCABULARY.—The October issue of the Chamber of Commerce *Journal* returns to the discussion upon the defects of the Vocabulary recently published by the Berne Bureau, and refers to the large number of complaints from commercial and banking firms which have been received by Chambers of Commerce in various parts of the United Kingdom. The matter in the *Journal* occupies nearly three long columns, and includes a mass of words given in the Berne Vocabulary which should and must be excluded from any commercial code if errors of the most natural kind are to be avoided. One firm points out that out of 20,000 words ending with the letter "a" no less than 840 have only one letter difference from others, and if anything like this proportion are bad throughout the book, no less than 11,000 words out of a total of 256,000 must be eliminated as useless from this process alone; the work of elimination being, in addition, of a most laborious and worrying nature. It is pointed out that as there are twelve other causes which interfere with the safe use of words from the Vocabulary, its valuelessness to the coding community can at once be seen. According to the Chamber of Commerce *Journal*, it is clear that the officials of the Berne International Bureau have failed to grasp the importance of this matter or they must have sought assistance from experts in Great Britain and other countries. That it is possible to obtain this expert assistance and to compile a vocabulary equal to the occasion we have good reason to assert. To some extent the work has already been done, and seeing that the Berne authorities were given a free hand in the use of common names and other advantages, the Vocabulary should have been free from many of the serious blemishes which unquestionably are conspicuous in it. Doubtless, this important subject will receive close attention at the forthcoming conference at Buda Pesth.

THE ELECTRIC ATHLETIC ASSOCIATION.—The Postmaster General will distribute the prizes to the members of this Association at a conversazione in the Holborn Town Hall, Gray's Inn-road, London, W.C., on Friday, the 15th inst.

TRADE WITH JAPAN.—An extremely useful and well-compiled "Commercial Guide and Trade Directory" of Japan has just been issued by the Bouverie Press, of Temple-chambers, London, E.C., or copies can be obtained of Messrs. Kegan Paul and Co., Charing Cross-road, London, W. The information given is of a character calculated to be of much service to British commercial houses, who will, we think, for the first time find set out such information as the following: List of Agencies of Japanese Companies in England, Articles Exported and Imported into Japan, Japanese Chambers of Commerce, Japanese Trading and other Companies, Consulates, Consulator Regulations, Customs Tariffs, Government Department, Lists of Officials of the Imperial Government, Parliament, &c.; several useful Directories, Weights and Measures, Monetary System, Military and Naval Departments, &c., &c. The Bouverie Press are well known as publishers of *Daily Tenders and Contracts*, which gives, in two editions daily, a complete list of outstanding contracts open, and other similar information of great value to manufacturers and others.

WEST HARTLEPOOL.—Electric tramways are being constructed in this town. The overhead trolley system has been adopted, and the work is being carried out by the Electric Construction Company. It is expected that the cars will be running by the end of the year.

WOLVERHAMPTON.—Col. W. E. Ducat held a Local Government Board inquiry on Friday last into the application of the Town Council for sanction to borrow an additional sum of £5,000 for electric lighting purposes. The Town Clerk (Mr. Horatio Brevitt) said the present loan was required for extending the electric lighting area. The capacity of their present plant was an equivalent of 8,000 8 c.p. lamps, and, as they had 7,936 lamps already connected, they could not accept any more orders until their system had been extended. They now proposed to put down machinery capable of supplying current to an additional 3,000 8 c.p. lamps, and with this they hoped to be able to tide over the winter. Mr. Brevitt added that within the last day or two they had received an application for 140 lamps, and they anticipated such a demand from fresh customers that they would have to make further extensions in the spring. Mr. F. Harman Lewis (borough electrical engineer) also gave evidence in support of the proposal, to which no opposition was offered.

WORCESTER.—The question of the extension of the electric light mains to Barbourne-road and Shrubbery-avenue is to be considered by the Electricity Committee.

COMPANIES' MEETINGS AND REPORTS.

Eastern Extension, Australasia and China Telegraph Company (Limited).

The forty-fourth ordinary general meeting of this Company was held on Wednesday at Winchester House, Old Broad-street, Sir John Pender, G.C.M.G., M.P., presiding.

The SECRETARY (Mr. F. E. Hesse) read the notice convening the meeting and the minutes of the last general meeting, which were confirmed.

The CHAIRMAN: Ladies and gentlemen, before moving the adoption of the report, I will, as usual, make a few remarks on the proceedings of the Company during the last six months. The gross receipts for the half-year under review have amounted to £264,138, against £247,681 for the corresponding period of 1894, showing an increase of £16,457. This increase is almost entirely due to the heavy gold mining traffic that has so suddenly sprung up with Western Australia. A few years ago the whole telegraphic traffic of Western Australia represented only a fraction of the Australasian traffic—now it is nearly one-third of it; mining

Digitized by Google

business is, however, very speculative, and it is imposaible to say whether the "boom" in Western Australia will continue or not. Meanwhile, the Western and South Australian Governments are improving and extending their land-line communications in order to efficiently deal with this abnormal traffic. The working expenses have amounted to £95,254, against £80,295 for the corresponding period of 1894, showing an increase of £14,959. Of this, £8,000 is due to heavier cable repairs during the past half-year than usual, and the balance to special station expenditure, such as new instruments, apparatus, electric lighting machinery, buildings, furniture, &c. The usual interim dividends at the rate of 5 per cent. per annum have been paid for the past half-year, amounting to £62,500; and the balance of revenue, £70,504, has been carried forward to the next account. As stated in the printed report, the fourth year of the working of the guarantee arrangement with the Australasian Governments resulted for the first time since it was entered into in a slight excess over the guaranteed figure. This, however, was solely due to the exceptionally heavy mining traffic already referred to. For the previous years the results were as follows:—For the first year there was a loss of £55,040, for the second year a loss of £43,558, and for the third year a loss of £12,384, making a total loss of £110.982, one-half of which was borne by the Governments and the other half by the Eastern Extension and its associated companies. During the half-year the maintenance ships have been, as usual, kept well employed on the various sections of the Company's extensive cable system, but the traffic has in no instance been interrupted owing to the cables being duplicated and in some cases triplicated. I have now given you pretty much the details of the last six months' working. There has not been anything very striking, but I think that in maintaining the dividend and in carrying forward a large sum to the next account we have done very well (hear, hear). I have just been looking over the remarks I addressed to you six months ago, and I find that were I to repeat them to-day they would not be out of place. I shall therefore not go largely into details to-day. There are a good many things floating in the air at the present moment, but until we know something more about them than we do at present, probably the less we say about them the better; but I can assure you of this—that we are closely watching all these matters, and that your interests will be vigilantly looked after whenever it may be necessary to take action. I may further assure you that your cables are, generally speaking, in good condition, and that the traffic is good. I also think that your dividend is a very good one as an interim distribution, and in conclusion you may take it from me that we are in a very satisfactory and prosperous position (hear, hear). I beg to move—

"*That the report and accounts of the Directors, now submitted, be received and adopted.*"

The Marquis of TWEEDDALE: I beg to second that.

The CHAIRMAN: If any gentleman desires to put any question I shall, as usual, be only too happy to answer it to the best of my ability.

Mr. SAMUEL SMITH inquired whether the investments forming the reserve fund were entered in the balance-sheet at cost price.

The SECRETARY replied in the affirmative. At page 10 of the report it was so stated.

The CHAIRMAN: I think it is a very nice statement to put before you as to our reserve fund (hear, hear).

Mr. SMITH acquiesced, and said he had been going to point out that, as the investments were taken at cost price, they showed a profit of something like £150,000.

The CHAIRMAN: We take no credit for that in the accounts.

Mr. SMITH: But it is a great gratification to know this.

The CHAIRMAN: Yes, it is. I am very proud to see such a reserve, because it is one which we could turn into cash at once if necessary.

In answer to a further remark by Mr. Smith relative to the expenses,

The CHAIRMAN said: Submarine cables are an uncertain property in regard to cost of repairs. We may have many repairs to-day, and possibly none again for some time to come. Of course, we have to meet these repairs, but, on the whole, I think our repairs are not excessive. I think it probable that we may look into this question of repairs, and place the matter before you in a different form. Instead of charging very much in one year, and perhaps a great deal less next year, we may perhaps be able to see our way to charge a fixed annual sum, and have what is called an equalised amount provided each year.

Mr. SMITH said his remarks were merely intended to elicit information. He took it that there had been an unusual expenditure for buildings, which was not likely to occur again.

The CHAIRMAN: We are going to build a handsome station at Hong Kong, which will cost us some money. We find as we go on that our staff increases, and we have to extend our accommodation. We have got a good service because we have good men, and we have to put them in as comfortable quarters as we can. In many cases we reduce our rent by building our own stations. He then put the motion and declared it carried unanimously.

Mr. JOHN NEWTON: I have much pleasure in proposing a vote of thanks to the Chairman and Directors for their services in the past half-year. I think that the Board may well be proud of the list of investments they show in their report. I do not suppose there is any other cable company that can show such a strong position. It is very gratifying to me to hear you, the Chairman of so strong a Company, enunciate the principle of charging an average sum for repairs. That will enable the shareholders to count with much greater certainty on equal dividends.

Mr. SAMUEL SMITH seconded the motion, which was carried unanimously.

The CHAIRMAN: I am not old enough to feel other than pleased when our shareholders congratulate us each six months. I think we are entitled to a little compliment from you, and I should feel disappointed if you did not pay it to us. When you do I assure you we appreciate it very much, because we desire to be always in touch with you. We also desire to maintain the dignity and position of our submarine telegraph system; and as long as it occupies the position it does at the present moment, not only the Directors, but those shareholders who have stood by us for so many years, ought to be proud of it (applause).

The proceedings then terminated.

Brazilian Submarine Telegraph Company (Limited).

The forty-fourth ordinary general meeting of the shareholders of this Company was held at Winchester House, Old Broad-street, on Wednesday, under the presidency of Sir John Pender, G.C.M.G., M.P.

The SECRETARY (Mr. Richard Collett) having read the notice convening the meeting, and the minutes of the last meeting, which were confirmed,

The CHAIRMAN said: As usual, gentlemen, I will go over the report and give you such additional information as will make the meeting interesting to you, and I hope I shall be able to show that it is satisfactory. The receipts for the half-year ended June 30, 1895, were £108,206; for the previous half-year they were £104,926, showing an increase of £3,280. The receipts from messages show an increase of £3,336, and those from miscellaneous receipts from interest, rents and transfer fees a decrease of £56, resulting in a net increase, as before stated, of £3,280. This increase results from growth in the telegraphic business with the West Coast of Africa, South Africa, and the West Coast of South America. Although we have carried a largely increased volume of traffic with Brazil and the River Plate Republics, we have not benefited much in money, but this is due to the fact that the exchange value of the milrei has averaged nearly a penny less, and that certain re-arrangements of, and reductions in, the rates came into operation during the half-year. The increase in traffic has, however, compensated for the loss that would otherwise have resulted from the reductions in the rates I have mentioned. As traffic grows, and circumstances permit, your Directors are pleased to find themselves able to lower the telegraph tariffs. I may take this opportunity of comparing some of the charges in operation when the word rates came into force with the tariff of to-day. For Pernambuco the rate was 9s. per word—it is now 3s. 6d.; for Rio de Janeiro the rate was 13s. 7d., for Uruguay 15s. 8d., and for Argentina 16s. 4d.—they are now 4s. 6d.; and for Chili and Peru the rates were respectively 21s. 4d. and 26s. 6d.—they are now 6s. 2d. I think that shows that while we have been progressing and doing a fairly good business, we have also had regard to those who are contributing to that business by giving them rates perhaps more largely reduced than could have been expected. Taking the expenditure side of the revenue account we find the total expenses chargeable against the half-year amounted to £21,129, which, compared with the previous half-year, viz., £36,772, shows a decrease of £15,643—due, I may say, to the absence of any heavy expenditure for repairs of cable, such as occurred during the previous half-year, when repairs cost £16,400. You will see that a great deal depends upon the amount we expend on the repairs of the cables. That is a quantity which we cannot at any time estimate, but I may say that when these repairs take place we always put in some new cable, and are always strengthening the old cable thereby. The general expenses in London and the working expenses at stations show decreases of £54 and £698 respectively. There is also a reduction of £1,641 in the service of the Debenture debt for interest and sinking fund. The expenditure contains two special items, viz., one of £1,172 for repairing and storing some 36 knots of cable recovered during the repairs near Pernambuco, brought home, put into good order, and made available for use again when required. The other is £1,181 special legal expenses incurred in settling a dispute involving a question of great importance, upon which the Directors were bound in your interests to obtain a judicial decision. Taking both receipts and expenses together, we have a profit of £82,086 for the half-year under review, compared with £61,822 for the preceding six months. This shows an increase of £20,264. To the profit for the half-year is added £4,324, the balance to credit of the revenue account brought forward from December 31, 1894, making a total of £86,410. Of this £30,000 has been transferred to the reserve. An interim quarterly dividend of 1½ per cent. was paid in June, amounting to £19,500. A similar dividend is now proposed, and also the payment of a bonus of 2s. per share, amounting together to £32,500. The balance of £4,410 is carried forward. The dividend proposed for the year is at the usual rate of 6 per cent. The bonus of 2s. equals 1 per cent.; therefore the total distribution is 7 per cent. for the year, or ½ per cent. more than was declared for the preceding year. Although the period we are dealing with was free from expenses for repairs, we have not been so fortunate in the current half-year, for on August 26th the St. Vincent-Pernambuco No. 1 cable was broken, about seven knots from St. Vincent. The repairing steamer "Mirror," of the Eastern Telegraph Company's fleet, was at once chartered, and she left Gibraltar on August 31st, arrived at St. Vincent on September 7th, completed the repair on the 9th, left St. Vincent on the 10th, and arrived at Gibraltar on September 17th. This, I am sure, you will consider a very expeditious and satisfactory piece of work. The cable was laid in 1874, and has therefore been submerged 21 years. After the repair it was found to be in excellent working order. I do not know that I can give you more encouraging words than these. It has been for a long time a question, What is the life of a submarine cable? Well, what with the repairs we make, the additions of new cable, and one thing and another, I think we can keep a cable alive for a very long time. That is satisfactory to you, because it shows that your property may continue longer than we expected; but we must not rely too much on that. We must have such a reserve as will enable us to meet any breakdown that may occur promptly and efficiently. The traffic between the West Coast of South

Digitized by Google

America and Europe, passing *vid* the lines of the Pacific and European Telegraph Company, continues to grow in a satisfactory manner, and I anticipate that very shortly a dividend will be declared by that Company. In the meantime we are receiving our proportion of the charges for carrying this West Coast traffic, which, prior to the formation of the Pacific Company, did not transmit by our system. Gentlemen, I have given you, as you will see, a very careful statement of our affairs. I have put before you a thoroughly satisfactory statement, and I have shown you that in the midst of the uncertainties, by which we are more or less surrounded, we are progressing, and from the way we are doing our work we are likely to progress. We are not in the happy position that we should like to be in with the Brazilian Government. For the 20 years during which we continued as their concessionaire we conducted the work in a most satisfactory way—so satisfactorily that I do not know that Brazil would have occupied the position she does to-day had it not been for the submarine telegraphs, which brought her into close contact with every mercantile community in the world. I think they ought to remember that. They ought to remember that while the pioneer Company exists and shows that it reduces the rates in a way that ought to be thoroughly satisfactory to the Government, they require a little attention, and not to be treated in the way in which the Brazilian Government has treated us lately. Some of the Brazilian newspapers have done a great deal to abuse us, and, I am sorry to say I read in a Brazilian newspaper that the odium which they are throwing upon us, or trying to throw upon us, is in some measure due to the interested parties apparently connected with the Western Company. The fault which I find with some persons connected with that Company is that they might look more after the dividends and interests of their shareholders and less to other considerations; and I hope that the shareholders of the Western Company will take up this question in earnest. We are doing well. We can go on as we are; but when I see a Company which I think ought to be much more prosperous than it is I think that the sooner the two companies are more closely allied the better. That ought to be the business of the shareholders of the two companies. I am quite ready. They have told me they are quite ready; but they are subject to the power of purchase by the Brazilian Government. If that sale does not take place promptly I think it will be wise on the part of that Company to see that the difficulties which exist now are removed. I am desirous of acting in a fair, straightforward spirit with them. So far as matters between the Government and the Brazilian Company stand, they are as follows:—In May, 1894, the Company sent a special agent to Rio with propositions from the Company to the Government, under which it was hoped arrangements would be made to meet the views of the Brazilian Government and increase the traffic with the telegraph department, and consolidate the working of the cable companies, having every regard for the interests and rights of the public. For reasons stated at a previous meeting the agent had no opportunity of entering upon the negotiations. I believe during a two months' stay they granted him two hours' interview. Early in 1895 further representations were made to the Brazilian Minister in London, having for their object the removal of all misunderstandings and the making of arrangements for the future of international telegraphy, which should afford every possible advantage to the people of Brazil, combined with a fair return to the Government Telegraph Department and to the cable companies. Under such an arrangement we hoped that all interests would be fairly dealt with and the service improved. Early in June last, at the request of the Minister of Industry, &c., our representative in Brazil presented to the Minister the views of your Directors, with an assurance of our desire to bring about a closer working arrangement with the Telegraph Department, with financial advantages to that Department and due regard to the other interests involved. We have not yet received a reply from the Minister, but there has lately been published in an official print in Rio de Janeiro a report upon the question from the Director-General of Telegraphs. It is very long, and is in the hands of the translator to-day; but, so far as we have gone into it, it raises questions as to monopoly, our alliance with the Western and Brazilian Telegraph Company, and other points, all of which it was our hope would be arranged to the satisfaction of the Brazilian Government in the negotiations your Directors have sought to bring about, and which they still greatly desire may yet be entered into with the Minister. I think I have told you pretty much all now that I ought say, but there is one subject which is before the public, and with which some of the newspapers are also dealing—I refer to the question of the little island of Trinidad. When we found that the Brazilian Government would not deal with us—in fact, practically refused to deal with us—we had to look round and see how the other part of the coast could be dealt with, and how we could maintain our traffic there, which formed a very large portion of our traffic with South America. We have erected new lines between Buenos Ayres and Valparaiso, thus connecting our system with that on the West Coast of South America, and the Western and Brazilian Company were parties to the erection of those lines which we are working now, and very satisfactorily. We have a very large traffic in the River Plate and on the West Coast, and we have to maintain an efficient service there, which we are able to do under existing cable arrangements. We are bound to keep lines for that traffic open, and we had to look around for the best way to get to the Argentine and Chili without being interrupted in any manner. We then found that this little island was unoccupied. It had been claimed at different times by different nations. The Portuguese say that they had it, the Brazilians say that they had it, and England says that she had it, but at the present time this small island is only occupied, as far as we can learn, by landcrabs; there was not a human being on it. We found that it would be a most excellent place for our purpose—a place which, practically, Providence had provided for the submarine telegraph system. We asked our Government to look into it, and, if free and unoccupied, to take it, so that it might be used as a submarine telegraph station. We asked for it for no other purpose except in the cause of submarine telegraph progress; and it is our business, having so far established it successfully, to protect it. Brazil has made a political question of it, but they are not likely ever to use it if they had it to-morrow. Let them have the sovereignty of it, if they please, but let it be used by us or any other parties—for we do not ask for its exclusive use—who choose to lay down a submarine telegraph there. Let it be used and kept as a telegraph station. It never can be used for any other purpose. I am quite sure you will agree with me that, while nations have their rights, they also have their duties; and if the Brazilian Government will deal with us as the nations of Europe deal with us, we shall be perfectly satisfied to meet them on fair terms, and in meeting them on those fair terms we shall give enormous benefits to their trade and advantages to those who trade with them. I will now move—

"*That the report of the Directors and the accounts to June 30, 1895, now submitted, be approved and adopted; and that a dividend be now declared of 3s. per share, making, with the interim dividends already paid, a total dividend of 6 per cent. for the year, and also a bonus of 2s per share, making in the aggregate a distribution of 7 per cent. in respect of the profits for the year ended June 30, 1895, the said dividend and bonus to be respectively free of income tax.*"

Mr. FREDERICK YOULE: I have much pleasure in seconding the resolution.

The CHAIRMAN: Before I ask you to approve this I will ask any gentleman to make any remark if he desires to do so; but I will first refer to a letter from Mr. Thompson, who urges upon us the impolicy of largely increasing our reserve fund. Our reserve fund is our stand-by; and to reduce it for the reason that he states—that a large reserve tempts others to come in and do the work—would be most unwise. He gives as an illustration of his reason the South American Telegraph Company, which came into competition with us. I am quite sure from what I hear and know of the traffic that if the South American Company had the choice of doing the work again they would not do it. I think they have quite enough to do with cable competition, and I think they will find it better to stick to their manufacturing work. We are on perfectly friendly relations with them, but, as I told them, and as I now tell you, they have not improved the position of submarine telegraphy since they became a cable company. They make very good cables, and I should like to see them prosperous, but I cannot approve of the course they have been pursuing. We ought not only to maintain but also to increase our reserve fund. It is there, and it belongs to you. We are not using it. If the time comes and it has to be divided, you are the people who will get your share of it. Therefore let us maintain the position which I think we have made; at all events, let us maintain it until we see smooth seas around us. If anyone now desires to put a question to me before I submit the resolution I shall be pleased to answer him in the best of my ability.

Mr. MICHAEL THOMPSON inquired whether there was any agreement between the Western and Brazilian Company and this Company prohibiting the laying of a competing line.

The CHAIRMAN, in reply, stated that they had an agreement for forty years with the Western and Brazilian Company, but under that Company's concession the Brazilian Government had power to purchase the Company's cables. If the Brazilian Government got possession of the interests of the Western Company, the Brazilian Submarine Company would be face to face with the Brazilian Government, and would then cease to be in any way connected with the Western Company. Therefore the Brazilian Government, if they bought up the undertaking of the Western Company, would deal with the Brazilian Submarine Company, or they ought to do so. It was for that reason the Directors of the Brazilian Submarine Company sent out a special agent with propositions for arrangements such as other telegraph companies have with India, with France, and with Italy. These were all businesslike arrangements, but the Brazilian Government would not see them or listen to them, and sent the Company's agent back without having made one step of progress. However, the present Brazilian Government has not been in office long, and he thought they would yet negotiate with the Company, and they would find after all, that the Company ought to be dealt with in a fair and reasonable way. The Western and Brazilian Company could not lay a competing line, but on acquiring that Company's undertaking the Brazilian Government could lay such a line. For his own part, however, he did not believe that the Brazilian Government would buy up the interests of the Western Company. The people who wanted to bring about the purchase saw that unless they urged on the Brazilian Government to buy, money which they expected to flow into their pockets would not reach them.

The motion was then carried unanimously, and resolutions were afterwards passed re-electing the retiring Directors, Lord Sackville A. Cecil and the Duke de Loulé, and the auditors, Messrs. Deloitte, Dever, Griffiths and Co. and Messrs. Gane, Jackson and Jeffreys.

Mr. ROBERT TAYLOR then proposed a vote of thanks to the Chairman and Directors, whose services he warmly commended, and whom he congratulated for having such a list of investments forming the reserve fund.

Mr. GEORGE C. SCRUTTON seconded the motion, which was carried unanimously.

The CHAIRMAN, in reply, thanked the shareholders for the strong confidence which they had expressed in the Directors. He had spoken plainly, and some of his remarks would probably not be appreciated by those for whom they were intended; but the first consideration of his colleagues and himself had been to see that the interests of the shareholders were fairly and properly respected. Their Company had been a marked success, and he would always do his utmost to take care that they were dealt with as an honourable body, which had done an immense deal of good, not only for Brazil, but for every country where trade and commerce were carried on.

The proceedings then terminated.

The Amazon Telegraph Company (Limited).

The first ordinary meeting of this Company was held yesterday at Winchester House, Old Broad-street, E.C., under the presidency of Mr. W. S. Andrews.

The SECRETARY (Mr. R. M. Cunningham) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, we have no report and no accounts to present. This is, as you know, simply a statutory meeting, just to let the shareholders know what progress is being made in what is, of course, practically, an entirely new undertaking, and therefore what I have to say will be pretty much in the nature of a catalogue. In the first place, with respect to the capital of the Company, it was £250,000, you will remember, in ordinary shares—25,000 Ordinary shares. We had applications for 30,250 shares; 25,000 shares were allotted unconditionally to applicants. Fortunately, the Company is in this position—that it has no other capital. There is no debenture capital, there is no Preference capital, and, therefore, whatever we may be fortunate enough to earn will be distributed among the shareholders alone. I am pleased to say that all the calls made have been paid up to the present time. The shares are now £5. 10s. paid, with the exception of 914 shares, which were all paid up in full. The shares, as you know, are of the nominal value of £10. Up to the present time—that is, up to yesterday—we are informed that 1,119 miles of cable have been manufactured, and it is expected that the total mileage will be completed by the end of November, or perhaps even a little earlier. All the apparatus is in hand, and the expedition, no doubt, will start shortly after the completion of the cable, and we may probably see our line in full working order pretty early next year. I think I ought to say a word as to the very satisfactory manner in which all the works have been executed by Messrs. Siemens, so far as we have gone. I have no doubt that that satisfactory work will be continued to the end of the chapter, and that as far as our plant goes we shall have a very first-rate cable. We shall have the best and most modern apparatus, and, therefore, the concern ought to work to a profitable end. The contractors and the Company's representatives and engineers have been up the river Amazon for the purpose of surveying the route, fixing the points at which the cable is to be landed, and arranging for the building of huts or small establishments for the offices and quarters, as far as possible, of the clerks employed. Therefore, every care has been taken well beforehand of the conditions under which the thing is to be worked. We expect to have this report shortly. We have not received it at present—we have simply heard that it is coming, but we expect to have it in the course of, I suppose, a fortnight, and then we shall be in a better position even than we are now to gauge the date at which the line will be finally completed; but it will be, at all events, as I have said, early in the coming year. There is only one other point which I have to mention. I daresay some of the shareholders have been looking out for a Stock Exchange quotation. We applied in the usual course for it, but there has been delay, owing to the concession having to be sent out to Rio for the attestation of the British Consul to certain signatures. That was one of the requirements of the Stock Exchange, and we were very happy to comply with it. The only thing we regretted was that it would interpose a little delay in the granting of a quotation. Otherwise everything is in order, and as soon as these papers get back we shall fulfil the necessary formalities, and your quotation will no doubt be forthwith granted. I think there is no other matter I have to detain you with. You are all business men, and no doubt you will be glad to go. Unless any gentleman likes to offer any remarks the meeting is at an end. There are no resolutions to be passed.

A brief discussion followed, and,

The CHAIRMAN, in reply, said: Before Mr. Griffith arrived I had mentioned that we anticipated the completion of the line early in the new year. As far as we have information at the office, it points to an earlier completion and opening of the line than we had ventured to anticipate. That is a favourable element, as far as it goes. With respect to the earliest dividend and dividends during construction, as the learned gentleman knows perfectly well—better than I, I imagine—a Company like ours is under the Joint Stock Companies Act, and has not a special Act enabling it to pay dividends out of the capital subscribed during construction. It, therefore, cannot pay anything until the earnings of the Company enable it to do so.

Mr. GRIFFITH: Could you not do so out of the subsidy?

The CHAIRMAN: We have not got the subsidy yet. With respect to the Stock Exchange quotation, I do not think I need say anything further. With regard to the traffic, we have not the reports, which are on the way, and which our worthy secretary tells us we shall receive in about a fortnight, but there is nothing of any discouraging character, so far as we know, to interfere with our our prosperity. With respect to the observation of Mr. Quilter as to the strides made by Brazil, it is perfectly true that Brazil is making great strides. There ought to be a very much quieter and more satisfactory feeling in Brazil, and that state of mind ought to lead to increased business and increased prosperity. You all, however, know that there has been a little something thrown across the path that has interfered with and thrown exchange rather backward than forward, and that is one of the points which makes prosperous and unprosperous companies. We may cite the Western and Brazilian and the Brazilian Submarine companies; with a low exchange their revenue is less. It does not affect us, but it does affect trade and commerce. This has rather thrown that back again. Then there is the excited state of political feeling, and the Brazilians are immensely excited over the rock of Trinidad. That, with the fear of something desperate occurring, has rather caused a stagnation or temporary pause in the advance which you were quite right in saying was taking place. We have sent our engineers and others to go carefully over this line because of the peculiarity of it and the newness of the endeavour to establish a communication of such great length in what we call a river. At the same time, as you know, the Amazon, where our line terminates—that is at Manaos, some thousand and odd miles up the river—is ten miles broad. When the flood season is on, its width is so large that the waters on the river are very little affected. There is not that amount of disturbance and flood that you would expect, from the simple reason of the gradual flow which the water takes over the low-lying lands around, and during that season the river is not 10 miles, but about 30 miles, broad. It is called out there the Mediterranean of South America, so it is not a river in the ordinary sense. There is one little bit of it—little relatively to the enormous length of the whole—where it is more like a river. It divides into three rivers, where the big Amazon comes into the Para. Otherwise this enormous width is all the way up. As far as we know at present, our engineers have found nothing of an adverse character at all. We should have heard of it if they had. We are told that this report is coming, but we should have been informed had there been anything to interfere with or render less promising the laying of this cable, and the result as regards its expected future. We had several reports—all of them favourable. None seemed to anticipate any difficulty, after investigating the charts, in the laying of this cable. We are, therefore, led to hope, seeing the careful way in which everything has been done, and the care taken in laying out the construction of the whole scheme, that the future ought to be prosperous. We hope so. We are all shareholders in it, as you know. A question was asked whether the subsidy would begin to be paid on the completion of the cable—the opening of the lines—or whether it would not be paid for 12 months after. We are advised that it becomes payable as soon as we can report that the lines are laid and open for business, and from the date of the contract, so it will go back. Our representative in Brazil is making inquiries with respect to the employment of native Brazilians, who, properly trained, are skilful telegraphists, and also as regards the best means of communication. It is singular that Mr. Quilter should have hit upon it, but we have already ordered several telephones with the object of establishing communication, which it is reported we can effect over the smaller lines, and which would then be worked without the application of skilled labour. Anyone can talk through a telephone, and carry out the instructions put upon it. We have therefore already taken this matter in hand, and the instruments are being made.

On the motion of Mr. GRIFFITH, seconded by Mr. QUILTER, a vote of thanks to the Chairman and Directors brought the meeting to a close.

Monte Video Telephone Company (Limited).

The annual general meeting of this Company was held yesterday (Thursday) at Winchester House, London, E.C., Mr. Herbert Ward (Chairman of the Company) presiding.

The SECRETARY (Mr. E. M. Reiss) read the notice convening the meeting.

The CHAIRMAN said: The position, as shown by the accounts, compares favourably with that of last year, in spite of one or two troubles which have befallen us during the past twelve months, troubles to which a telephone business like ours is peculiarly liable, and which serve to retard that progress which would otherwise be made. One of these troubles is damage to our plant by storms. In the early months of this year Monte Video was visited by many storms, and our wires and posts were much damaged. On March 25th, during a heavy thunderstorm, the main post, with its many cross arms, on the roof of our central building, was struck by lightning, and all the wires coming out of the central office were severed, and communication with subscribers was for a time totally disconnected. A word of praise is emphatically due to our general manager in this matter, for, by his alertness and energy, and by keeping men at work night and day, the damage was repaired within five days. The activity displayed in restoring communication with subscribers added in fact to the local prestige of the Company, and quite counteracted the harm which was feared in the first instance would be done to the Company's business. The loss sustained by this lightning accident was entirely recovered from the fire insurance company, who settled our claim very promptly, so that this accident has not added to our working expenses, but I may mention this event as one showing the dangers we are always open to, and which are naturally beyond our control. Another matter, however, which has helped to increase our maintenance charges is the constant changing of posts on the roofs of houses and buildings, owing chiefly to caprice on the part of the property owners. This is a matter of peculiar difficulty to which our manager is always giving his attention. It is owing to these causes that our working expenses are some £800 more than last year. Another trouble was loss of subscribers. Our monthly returns show that throughout the year our losses have been fairly made up by new subscribers gained, and had it not been for the unfortunate loss of the police department, who subscribed to 49 of our instruments, our present number of subscribers would be about equal to the number at this time last year. The local opposition company, however, through political influence on the occasion of the change of ministry last winter, succeeded in taking this police service from us. This opposition company has no multiple board, and cannot, therefore, give such efficient service as our own company, and we are already advised that the police bureau are very dissatisfied and are threatening to return to us. Notwithstanding this loss our total receipts from subscribers are only £157 less than last year. In view of this loss and of there being no increased revenue to apparently justify the capital outlay for the year of £985, the Directors have considered it right to use a portion of the depreciation fund, created for the purpose, to cover this item of expenditure. I would next like to mention that Mr. Sanford, one of your Directors, being just now engaged on business in the River Plate, has been able to visit our head office in Monte Video, and is in constant communication with our manager. The advantage of having a member of the Board at headquarters is obvious. Mr. Sanford is thus able

Digitized by Google

to personally consult with Mr. Harispurn, our local agent and attorney, and to dispose of questions promptly, to the great assistance of the manager, not only temporarily, but as regards the future conduct of the Company's business. Now, on the other side of the picture we show a new item of income of £187 in the shape of interest on our investments, which, moreover, stand at yesterday's closing middle prices at a capital appreciation of nearly 8 per cent. In other words, securities which are taken in our balance sheet at their cost price of £8,693 would, if sold to-day, realise about £9,300. While adding substantially to our reserve fund, and carrying forward a larger sum than a year ago we are able to maintain the dividend of 4 per cent. declared last year on the Preference shares, so that in spite of the little troubles I have explained to you I think you will agree that the position, as revealed by the accounts, is a satisfactory one, and is even stronger than at this time last year. I now formally move :—

"That the report and accounts as presented be received and adopted."

Mr. F. W. JONES seconded the resolution, and it was agreed to without discussion.

The CHAIRMAN then moved

"That a dividend at the rate of 4 per cent. per annum on the Preference share capital of the Company be declared for the year ending July 31, 1895, and that the same be paid forthwith."

Mr. E. F. POWERS seconded, and it was carried.

On the motion of the CHAIRMAN, seconded by Mr. H. SMITH, Mr. C. H. Sanford, the retiring Director, was re-elected ; and Messrs. Gerard Van de Lind and Son were re-appointed auditors.

A vote of thanks to the Chairman terminated the proceedings.

NEW COMPANIES, STATUTORY RETURNS, &c.

ACETYLENE ILLUMINATING COMPANY (LIMITED).—The statutory return to September 19th has been filed. The nominal capital is £21,000, in £1 shares, and 4,000 of these have been subscribed for and allotted. A call of 2s. 6d. per share has been made.

AURORA ELECTRIC LIGHTING AND DISTRIBUTION COMPANY (LIMITED).—The annual return to October 9th has been filed. 5,935 shares have been taken up out of a capital of £25,000, in £1 shares, and 5,000 have been issued as fully paid. The full amount has been paid on the remainder.

BUENOS AYRES ELECTRIC LIGHT COMPANY (LIMITED).—The annual return of this Company, made up to June 11th, has just been filed. The nominal capital is £100,000, divided into 9,986 Ordinary shares of £10 each, and 70 Founders' shares of £2 each. All the latter have been subscribed for, but nothing has been called thereon.

BICKLEAND COMPANY (LIMITED).—The annual return of this Company, made up to October 2nd, has just been filed. The capital of £50,000 is divided into £10 shares ; 2,030 of these have been taken up, and 1,000 have been issued as fully paid. The full amount has been called on the remainder, resulting in the payment of £10,223, and leaving £77 in arrears.

CONNOLLY BROS. (LIMITED).—The statutory return to October 11th has been filed. Out of a capital of £20,000, in £5 shares, seven have been subscribed for and allotted. The full amount has been called and paid.

ELECTRIC CONSTRUCTION COMPANY (LIMITED).—The annual return to September 26th has been filed. The nominal capital is £400,000, in 150,000 Ordinary and 50,000 £7 per Cent. Cumulative Preference shares of £2 each. 110,000 Ordinary and 16,343 Preference shares have been taken up, and all the Ordinary and 13,145 of the Preference have been issued as fully paid. The full amount has been called and paid on the remaining 3,198 Preference shares.

CITY NOTES.

MEMORANDA—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver, 31d. per oz. (Oct. 31st). Consols (2¾ per cent.) 106⅞—107⅛ for money, 106⅛—107 1/16 for account ; 2½ per cent. 104¾—105 (Oct. 31st). Stock Exchange Settling Days : Consols, Nov. 6th ; Stocks and Shares Continuation Day, Nov. 12th ; Ticket Day, Nov. 13th ; Pay Day, Nov. 14th ; Mining Share Carry-Over Day, Nov. 11th.

ANGLO-FRENCH (COLONIAL) MINING TRUST (LIMITED).—At the statutory meeting of this Company on Monday last the Chairman (Mr. James Burnett) announced that the Directors had secured an interest in the Ward Electrical Car Company. He said that there was no doubt that electricity would be the motive power of the future, and he thought the time was not far distant when the streets of London would be without horses. He had been informed that the drawback to electric cars in the past had been their weight, but he believed that Mr. Ward had now overcome this difficulty, and he was prepared to put on the streets 'buses and carriages that would run even lighter than the ordinary horse cars. There seems to be a smack of ancient history in this report, more particularly as the Chairman talks of 50 per cent. dividends in the near future. Surely this has been previously prognosticated.

BRITISH ELECTRICAL MANUFACTURING AND ENGINEERING COMPANY (LIMITED).—As stated in our last issue, a company has been formed under the above title. It will be an amalgamation of the St. Martin's Electrical Manufacturing Company and the manufacturing departments of Messrs. Laing, Wharton and Down, of New Bond-street, London. Mr. C. L. Barker has been appointed consulting engineer to the new Company, and the vendor, Mr. T. Duncan Dundas, has been appointed manager. £12,500 (£2,500 in cash, £1,000 in debenures, and the balance in fully-paid shares) is the purchase price fixed.

CASTNER-KELLNER ALKALI COMPANY (LIMITED).—Letters of allotment in the recent issue of shares in this Company have, we learn, been posted.

CENTRAL CHILI COPPER COMPANY (LIMITED).—The Directors of this Company invite tenders for about 5,000 Six per Cent. Accumulative Priority shares of £1 each, at a price not below par. The subscription is invited from existing shareholders, and if not taken up by them the Directors will proceed to allotment on the 11th inst. upon applications already in hand for the whole amount. The present issue is made in consequence of the satisfactory reports from the Manager in Chili, upon which the Directors propose to take steps to increase the output of the mines by further developing and putting down additional machinery, &c.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended October 27th were £977, against £948 in the corresponding week of 1894, an increase of £29. The total receipts for the half-year amount to £14,678, against £14,811 for the corresponding period of 1894.

EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY (LIMITED).—A drawing of 381 Five per Cent. Mortgage Debentures of this Company will take place at the offices, Winchester House, Old Broad-street, E.C., on Friday, the 15th inst., at noon. The drawn debentures will be paid off on January 1st next, and due notice of the numbers will be given.

ELECTRIC TRACTION IN ITALY.—A Company, entitled the Unione Italiana Tramways Elettrici, has just been formed in Genoa. The capital of the Company is £120,000.

ELMORE'S PATENT COPPER DEPOSITING COMPANY (LIMITED).—The Directors of this Company report that the profit on the last year's manufacturing account is £4,557, and after writing off the Company's general and trading expenses, the trading account shows a net profit of £2,253 carried to the credit of profit and loss, as against a loss of £6,858 in the previous year. This improvement has been effected without any increase in the Company's working capital, out of which £5,202 has had to be spent in necessary additions to plant and buildings. The additions to plant are described as specially valuable, and are working satisfactorily. The orders received have increased from 706 in the preceding year to 1,531 in the present year, whilst the deliveries to customers have been nearly four times greater in volume and practically three times larger in value, notwithstanding that the average selling price has been over £12 per ton lower. Prices are, however, again ruling higher. The working expenses show a great decrease with the increase in the business done ; in fact, the rate of manufacturing cost has fallen by over 50 per cent. The profit and loss account shows a net profit for the year of £480. The business is described in the report as having now reached a stage when further capital can be reasonably asked for and profitably employed in its extension. The shareholders will therefore be asked at the meeting held to-day to increase the Board's borrowing powers, giving them power to borrow, as may be required, up to £100,000, and the debentures proposed to be issued will, in the first place, be formally offered to the shareholders. It is also proposed to reduce the ordinary share capital from £2 to £1 per share.

GROSSE LEIPZIGER STRASSENBAHN-GESELLSCHAFT.—A Company with this title has just been formed in Leipzig for the purpose of taking over the undertaking of the present English Tramway Company of Leipzig. The Company, which has a capital of £225,000, has been promoted by some German banks and the Gesellschaft für Elektrische Unternehmungen, propose to extend the present lines and equip the entire system electrically.

GUILDFORD ELECTRICITY SUPPLY COMPANY (LIMITED).—It is stated that sufficient capital has now been subscribed to float this Company, and that the shares applied for will be immediately allotted. Mr. W. J. Perkins has been appointed secretary of the Company.

INDO-EUROPEAN TELEGRAPH COMPANY (LIMITED).—The Board of Directors of this Company have declared an interim dividend, for the half-year ended June 30th last, at the rate of 5 per cent. per annum, free of income tax. The dividend is now payable.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 27th ult. amounted to £1,075. The amount for the corresponding week last year was £901 ; increase, £174.

METROPOLITAN ELECTRIC SUPPLY COMPANY (LIMITED).—The transfer register of this Company will be closed from this day (Friday) to Friday next inclusive, to prepare for the payment of an interim dividend.

SOCIETE GENERALE BELGE D'ENTREPRISES ELECTRIQUES.—A Company bearing this title, and having a nominal capital of 6,000,000fr., has just been formed in Brussels. Though the Company will carry on a general electrical business, special attention is to be devoted to the exploitation of traction enterprises.

STOCK EXCHANGE NOTICES.—The Stock Exchange Committee have ordered 17,139 "A" shares (Nos. 01 to 017,139) of the Edison and Swan United Electric Light Company (Limited), to be quoted in the official list

VICTORIA ELECTRIC RAILWAY AND LIGHTING COMPANY (LIMITED).—A meeting of the debenture-holders of this Company will be held at 8, Austin Friars, London, E.C., on Wednesday next, the 6th inst., at 2 o'clock.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the week ending October 25, 1895, after deducting 17 per cent. of the gross receipts payable to the London-Platino Brazilian Telegraph Company (Limited), were £3,203.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861—1878.

No. 912. [Vol. No. 2. XXXVI.] FRIDAY, NOVEMBER 8, 1895. PRICE SIXPENCE.

NOTES.

At the last meeting of the Hull Corporation Electric Lighting Committee a Report by the late Borough Electrical Engineer was presented, in which a change over to the now fashionable 220-volt lamp system was emphatically recommended. It was ultimately decided that Mr. GIBBINGS' Report should be entered on the minutes and its consideration deferred until after the forthcoming Board of Trade Conference.

In the case of extensions, and where one is working under Orders dating back as far as 1883, the 220-volt lamp idea need meet with no difficulty worth mentioning. But when we come to apply the idea to existing networks or to make the alteration under more modern Orders, several difficulties arise. Apart from the question of the durability of 220-volt lamps, there is the question: Who is to pay for the first batch? Mr. GIBBINGS proposes to settle this matter in right regal style by giving all his customers new lamps for old, and he estimates that after allowing for the money derived from the sale of the discarded 110-volt lamps, the change-over can be effected at a net cost to the Corporation of £1,500.

MR. GIBBINGS' "short way" is undoubtedly just, and where only some 15,000 lamps are concerned it is financially quite feasible. It would, however, be a somewhat expensive method in the case of concerns having, as many of the London companies have, 80,000 to 100,000 lamps connected. The remedy is evidently better suited to small rapidly-growing concerns than to large well-developed slowly-expanding businesses; more feeders would probably prove the better plan in the latter case. The Board of Trade also will, no doubt, have something to say in the matter wherever the electric supply is being carried on under a modern Order. It will be interesting to see whether that august Department will subscribe to the dogma of the infallibility of 110-volt switches and cut-outs when exposed to double the pressure allowed for.

THE decision which the Leicester Town Council came to last week to continue their electric light fitting business was a very natural one under the circumstances. No one is anxious to forego a lucrative trade, and least of all when the arguments brought forward against it are contradictory and irrelevant, and when it is possible to make out a very plausible, not to say forcible, case. Private trading by a municipality may be opposed on principle or on the ground that the work done is bad. At Leicester the local wiring firms merely deprecated municipal competition on purely personal grounds. As to the allegation that the Corporation did not adhere to its own wiring rules and took undue advantage of its position to secure wiring orders, these were satisfactorily disposed of by Alderman LENNARD in the course of his lengthy speech.

WE ourselves are, and ever have been, in favour of restricting municipalisation within the narrowest possible limits, on the ground that jobbery will inevitably creep in, and that the emulation of municipalities is not, in plain business matters, an adequate substitute for the competition of companies. At the same time, the electric lighting business once embarked on, the wiring business, especially in provincial towns, is an almost inevitable sequel. As Alderman LENNARD put it, "the success of the department to a very large extent depended upon the kind of fittings which were used," and the kind of fittings which would in all probability be used by small local firms is better imagined than described. Gas concerns certainly do gas-fitting better than the average local firm, and the same no doubt holds good for electric lighting. An obvious and, we think, effective way to secure good wiring and avoid the disadvantages of municipal trading would be to warn every intending consumer that his wiring will have to conform to standard, to fix that standard reasonably high, and to rigidly enforce the regulations by means of a small and competent staff of well-paid inspectors.

THE Birmingham Town Council were recently bold enough to grant provisional permission to the Birmingham Central Tramways Company to work the Nechells section of their network on the overhead trolley system. On Monday the ratepayers of the district concerned met in their might. The trolley and its appurtenances do not certainly possess "the fatal gift of beauty," but what modern "improvement" does? We can, however, imagine many a worse disfigurement than a line of steel poles with "ornamental" brackets, and then, as one of the speakers remarked at the meeting in question, "as for defacing property, some of it was of such a character that the more it was defaced the more it would be improved." No; the trolley in all its original hideousness was not to be tolerated; but it has now cast off much of the crudity of its early

Digitized by Google

youth, and its progress will most certainly not be long retarded by mere selfish arguments, such as were used at the Duddeston Ward Hall. In the early days of steam railways, landowners thought they had won a famous victory when they kept the accursed thing away from their property. In 1895, frontagers are playing the same part in regard to electric street railways. To-day many a landowner bitterly regrets his famous victory; to-morrow many a houseowner will do so likewise.

THAT it is sometimes, if not always, economical to use condensers for steam plant in electric supply stations is shown by the statements of Mr. WILLIAM CROSS in his Paper on "The Surface Condensing Plant at the Newcastle and District Company's Electric Light Works," an abstract of which appears in another column. This condensing plant has been running since 1892; and though troubles were experienced at first, these were easily overcome; and the plant has been successfully worked on a series of six-months' runs without stoppage and practically without attention. Paying for coal at the same rate as before, the expense per unit for coal has fallen nearly 50 per cent., and that of water about 70 per cent., since the introduction of the condenser. And though it is probable that a number of other causes have also influenced these results, and the share in them which is due to the condenser may not be quite determinate, the improvements are large enough to warrant the deduction that a considerable economy in coal and water has arisen directly from the use of the condenser. We could have wished, however, that Mr. CROSS had been able to make a closer statement of the benefits directly arising from this addition to the generating plant. One would like to know what was the additional capital outlay, and how much is annually spent on repairs, &c. With these supplementary data it would be possible for an engineer to arrive at a far more accurate estimate of the advantage he might expect to derive from a condenser than could possibly be obtained from a mere statement of the savings in coal and water, savings which it is very well known are almost sure to be made.

MR. BRADLEY'S Paper on "Phasing Transformers," an abstract of which appears in this week's issue, presents several points of interest. The apparatus possesses no motive parts, and transforms an ordinary alternating current into a current suitable for alternating motors. The method adopted for making the phase of the induced currents independent of the load is instructive, and the inventor seems to have attained considerable success in the construction of condensers, since he has apparently made one of 2·4 microfarads capacity, capable of withstanding the alternating pressure of 3,000 volts, and occupying the space of a cube whose side is only 4in. long. Nothing, however, is said about efficiency. For a ½ horse-power motor the condenser above mentioned is needed, the pressure being 1,000 volts and the frequency 140. Under these circumstances, assuming an ordinary power factor for the condenser, this would absorb quite 50 watts, or nearly 15 per cent. of the output of the motor. Nor would this percentage diminish with larger power motors, and for currents whose frequency is 70 instead of 140 the percentage would be doubled. Moreover, there are the losses in the *two* specially-wound transformers to consider, besides those in the motor itself. These considerations partially explain, and we hope only partially, the fact that for the ½ horse-power motor a 75 kilowatt dynamo was used.

Telephonic Communication in Madagascar.—A line of telephone was completed and put in operation on the 1st inst. between Tamatave and Tananarivo.

The Hargreaves-Bird Electrolytic Cell.—Owing to pressure on our space, we have been compelled to hold over until our next issue a lengthy letter on the Hargreaves-Bird electrolytic cell, which has been sent us by Mr. Hargreaves.

Cable Interruptions and Repairs:—

	Date of Interruption.	Date of Repair.
Cadiz-Teneriffe	Sept. 25, 1895.	.....
Maranharn-Para	Oct. 10, 1895.	Nov. 4, 1895.
Bonny Cameroons	Oct. 30, 1895.	Nov. 5, 1895.

The Vienna Elektrotechnische Verein.—The *Zeitschrift für Elektrotechnik* of Vienna, in its issue of November 1st, states that the Archduke Carl Ludwig of Austria has consented, in accordance with the wish of the Vienna Elektrotechnische Verein, to become the patron of that institution.

Horseless Carriages.—No less than three "syndicates" with horseless carriage titles have been registered within the last week. These are the Automotive Syndicate (Limited), the English Automobile Horseless Carriage Syndicate (Limited), and the Horseless Carriage and Motor Cycle Company (Limited). Clearly the horseless carriage is to be boomed and the horse carriage is doomed.

Personal.—It has been decided by the friends of Mr. W. T. Ansell, traffic manager of the Eastern Telegraph Company, to commemorate the fiftieth anniversary of his entry to the telegraph service (of which service he is the *doyen*) by inviting him to a dinner at the Holborn Restaurant, London, on Thursday next, on which occasion a presentation will be made to Mr. Ansell as a souvenir of the event. Mr. J. Denison Pender will occupy the chair.

Vacant Appointment.—The professorship of applied physics and electrical engineering at Heriot-Watt College, Edinburgh, has become vacant, and the Governors will receive applications for the post not later than November 22nd. The duties will commence on January 1st next. The salary is £400 per annum. Particulars can be obtained from the Principal of the College, 20, York-place, Edinburgh. Some further particulars will be found in our advertisement columns.

Board of Trade Revised Regulations.—A Conference between the Board of Trade and the objectors to the revised "REGULATIONS AND CONDITIONS FOR SECURING THE SAFETY OF THE PUBLIC AND FOR ENSURING A PROPER AND SUFFICIENT SUPPLY OF ELECTRICAL ENERGY" will be held at 11 o'clock on Tuesday, November 19th. As the number of objectors is somewhat large, the meeting will in all probability take place at the Westminster Town Hall, Sir Courtenay Boyle presiding.

Institution of Electrical Engineers.—The Institution of Civil Engineers have kindly consented to permit the meetings of the Electrical Engineers to be held in their new building, but inasmuch as there is some doubt as to whether the building will be sufficiently advanced to allow of the use of its lecture hall on the 14th inst., the Council of the Institution of Electrical Engineers have decided to postpone the opening of their Session until the 28th inst.——The Annual Dinner of the Institution will take place at the Freemasons' Tavern on Friday, November 29th.

Galvanometers on Board Ship.—Who ever has heard of the ordinary Thomson astatic galvanometer being used at sea? We learn, however, that on a recent cable-laying expedition with which Mr. H. W. Sullivan was associated the final tests before submersion of the various lengths of cable on board were made with one of these instruments with excellent results. At the time the ship was anchored some miles distant from the

Digitized by Google

land in perfectly calm water, and save for an occasional oscillation of a few scale divisions, due to the otherwise imperceptible ground swell, the readings were steady throughout. During the tests all the machinery on board was stopped. This probably is the first instance on record of the "astatic" being practically used on the ocean.

Lightning.—By signals observed from the coastguard look-out at St. David's on Thursday last week, it was seen that assistance from the mainland was required on the Bishop Lighthouse, seven miles off. A boat set off through the heavy sea to render assistance. It was found that the building had been struck by lightning, the electric discharge shattering everything in its course, and causing great consternation to the three men stationed on the rock, one of whom had a narrow escape. Fortunately the lantern and fog-signal apparatus were uninjured. The damage within the tower and living rooms, however, was considerable. From time to time representations have been made that both the Smalls and Bishop lighthouses should be connected with each other and the mainland by telephone, and those who have taken interest in the matter are hopeful now of achieving their object.

Hull.—At a meeting of the Hull Corporation Electric Lighting Committee held last week, a report from the late engineer, Mr. A. H. Gibbings, was presented. In this report Mr. Gibbings recommended the adoption of a house pressure of 220 volts in place of the existing pressure of 110 volts. The actual cost of changing over at the present time, or at least within the next twelve months, would be roughly about £1,500. The Chairman said that the only question was whether the Board of Trade would allow them to use the system. The actual cost of the alteration would be £3,362. 13s. 9d, but it was estimated by the engineer that there would be a return from sale of re-placed lamps, and an increased number of customers, which would leave the actual cost of the complete alteration at £1,525. 1s. 2d. It was ultimately resolved that the report be entered on the minutes, and its consideration deferred pending the coming conference with the Board of Trade.

The Rating of Fuse Wires.—In a Paper on "The Rating and Behaviour of Fuse Wires," read by Messrs. Stine, Gaytes and Freeman before the American Institute of Electrical Engineers, the authors describe a series of experiments, by which they are led to the following conclusions: (1) Covered fuses are more sensitive than open ones. (2) Fuse wire should be rated for its carrying capacity for the ordinary lengths employed. (2*a*) When fusing a circuit the distance between the terminals should be considered. (3) On important circuits fuses should be frequently renewed. (4) The inertia of a fuse for high currents must be considered when protecting special devices. (5) Fuses should be operated under normal conditions to insure certainty of results. (6) Fuses up to 5 amperes should be at least 1½in. long, ½in. to be added for each increment of 5 amperes capacity. (7) Round fuse wire should not be employed in excess of 30 amperes capacity. For higher currents flat ribbons exceeding 4in. in length should be employed.

Disturbances Caused by Tramway Earth Returns.—At the meeting of the Elektrotechnischer Verein of Berlin a few days ago, at which the Secretary of State, Herr von Stephan, acted as chairman, an important statement was made by Dr. Frölich, on behalf of Messrs. Siemens and Halske, with regard to the disturbance likely to be caused to the Reichsanstalt by the use of the earth return on the proposed Berlin-Charlottenburg electric tramway. As will be remembered, Prof. Kohlrausch, at a former meeting of the Verein, objected to the use of the earth return on the line in question on the ground that stray currents caused an enormous disturbance of the delicate measuring and testing instruments at the Reichsanstalt (see *The Electrician* of June 21st last, Vol. XXXV., p. 248). He also pointed out the way in which the Reichsanstalt could be made to withdraw its opposition. Dr. Frölich now states that means appear to have been found to render the earth currents innocuous. These currents, Dr. Frölich argues, are not stray currents, but pass from the rails through the earth to the generator in curves which can be accurately ascertained. Such determinations of the curves have been made in the Siemens laboratory on large models, and latterly on the Dresden electric tramway the accuracy of the method was tested and found trustworthy. A reliable method has, therefore, been found for ascertaining the exact course of the earth return current. It is proposed to connect metal conductors at certain intervals to the rails, and to lay these in the direction of the earth return current curve. Buildings for which special protection is desired are to be encircled by a number of wires, which may be joined to a cable the position of which will be fixed by the direction of the curve, previously determined. The capital cost of compensation circuits of this kind will not, it is said, be very considerable; but, of course, attention must be paid to the action of them, and also frequent tests must be made, as the varying value of the earth return current depends to a certain extent on weather and season, and will thus influence the direction of the curve. These conditions have been met by the adoption of regulating resistances placed in each compensation circuit. It is hoped that in using this system all objections to the use of the earth return in tramway work will be overcome, and disturbances reduced to a minimum.

Carborundum.—In a Paper published in the *School of Mines Quarterly* (Columbia College, U.S.A., No. 16, p. 73-79) Mr. J. A. Mathews gives a description of some works which have been started for the manufacture of carborundum by the aid of electricity. The process is carried on in a furnace, the walls of which are built of vitrified bricks upon a masonry foundation 3ft. wide by 8ft. long. Carbon electrodes 1ft. long by 2in. in diameter, and which may be as many as nine in number, project from the end walls. The carbons of one end are separated from those of the other by a distance of 5ft. to 5½ft. For a fuller description of the furnace we must refer our readers to English patent 17,911, 1892. The charge, which is a mixture of four parts of coke ground to an impalpable powder, with five of good glass sand, and one or two of salt, fills the furnace, except the region between the electrodes, where is laid a core of loose carbon. Electrolytic action is prevented by the use of an alternating current. The current is passed for about eight hours, and the furnace cooled, when a hollow cylindrical mass of carbon crystals, 4in. or 5in. thick, is found surrounding the carbon core, whilst a thin layer of soft greasy-feeling graphite separates the carbon from the carborundum, beyond which is a thin layer of light-coloured, amorphous carborundum, and beyond this again a portion of the charge, which is unaltered, with the exception that the salt has been fused. The raw product is crushed in a pan by hard steel rollers, boiled for a week in dilute sulphuric acid to remove iron and sodium silicate, sifted, and the finest powders graded by the length of time they are found to float upon water when stirred up therewith. The carborundum is now fit for use as a polishing powder, or can be formed into grindstones. Carborundum crystallises in the hexagonal system, and the crystals vary in size from a fraction of a millimetre to 3mm. in their largest dimensions. They have a specific gravity of 3 12, and the colour, which is probably due to the small percentage of impurities—viz, Fe_2O_3, Al_2O_3, CaO, MgO, &c.—varies from greenish to yellow and sapphire-blue. It has not yet been determined which is the harder, the diamond or carborundum, the brittleness of the crystals of the latter causing a difficulty in ascertaining the point. Carborundum is not suitable for the first rough treatment of the diamond, but it is used successfully in the polishing process. Analysis gives for it the formula SiC, the reaction of its formation being represented as $SiO_2 + 3C = SiC + 2CO$. It is unaltered by any of the ordinary mineral acids, and is unaffected by any heat short of that of the electric arc. For a further description of its chemical properties, and of the methods employed in the analysis of carborundum, we must refer our readers to the original memoir. The author states that carborundum appears to be suitable for most abrasive purposes, and there is especially a large application for it in grinding and cutting glass, the same amount of material doing much more work and acting more quickly than any abrasive now used. Wheels made from carborundum are used in grinding the necks of the Westinghouse incandescent electric globes and unless the wheels grind from 12 to 15 times as many globes as the emery wheels formerly used, they are returned marked "Not good."

ELECTROMAGNETIC THEORY.—LXXVII.*

BY OLIVER HEAVISIDE.

(*Continued from page 807, Vol. XXXV.*)

§ 303. In the other way of simplifying the general determinantal equation described at the close of § 298, we reduce it to the form (109), which indicates that we have the set of normal systems corresponding to $sl=(n-\frac{1}{2})\pi$, and in addition, the set corresponding to $(Z_0q)^2=R^2$. So (100), the solution for a point charge, is reduced to

$$V_1=\frac{(R\sin+Z_0s\cos)sy\,.\,(R\cos+Z_0s\sin)s(l-x)}{(q^2Z_0^2-R^2)\cos sl}\frac{sQ}{S}, \qquad (138)$$

showing the potential at x on the right of y due to Q initially at y itself. Let $V=U+W$, where U is the regular part, and W the extra part. Then by the expansion theorem (30), we obtain

$$U=\frac{2Q}{Sl}\Sigma\epsilon^{pt}\frac{(R\sin+Z_0s\cos)sy\,.(R\sin+Z_0s\cos)sx}{R^2+(Z_0s)^2}, \qquad (139)$$

subject to $\cos sl=0$. And, by the same process, we find

$$W=-\frac{Q}{S}\Sigma\epsilon^{pt}\frac{q\epsilon^{q(x+y-l)}}{\left(1+\frac{2p}{Z_0}\frac{dZ_0}{dp}\right)\cosh ql}, \qquad (140)$$

ranging over the roots of $R^2=(Z_0q)^2$. The sum of U and W is the expression for the potential at time t on either side of the source.

As an example, take $Z_0=R_0$, a mere resistance. Then there is just one extra q, of value $R/R_0=h$, say. To balance the resistance R_0 at $x=0$, there is a permittance of amount $-S/h$ at $x=l$.

Now, if we put $Q/S=1$, and $t=0$, in $U+W$, it represents u, the appropriate unit impulsive function. It need not be written out, as its form is obvious. Integrating the product of u and $f(y)$ with respect to y therefore expands $f(x)$ in the normal functions in question. In particular, if $f(x)=1$, we obtain the expansion

$$1=-\frac{\epsilon^{hx}(1\epsilon^{-hl})}{\cosh hl}+\frac{2}{l}\Sigma\left(\frac{h}{s}\pm1\right)\frac{(h\sin+s\cos)sx}{h^2+s^2}, \qquad (141)$$

in which the + sign is to be used in the odd terms, and the − in the evens. Introducing the time factors, as usual, shows what the initial uniform state changes to later on.

The expansion (141) may be verified by the conjugate property of the normal systems. Remember that there is one terminal condenser. So, assuming

$$1=A_0\epsilon^{hx}+\Sigma A(h\sin+s\cos)sx, \qquad (142)$$

we must have the identity

$$S\int_0^l\epsilon^{hx}dx+S_1\epsilon^{hl}\times0=A_0\left\{S\int_0^l\epsilon^{2hx}dx+S_1\epsilon^{2hl}\right\}, \qquad (143)$$

which gives A_0, and also

$$S\int wdx+S_1h\sin sl\times0=A\left\{S\int w^2dx+S_1h^2\sin^2sl\right\}, \qquad (144)$$

which finds A. Here w stands for the general normal function in (142). The 0 which occurs stands for the initial potential of the terminal condenser. S_1 is its permittance, $=-S/h$. Carrying out (143), (144), we shall arrive at the coefficients in (141), and verify that expansion.

An interesting modification may be mentioned. Put a real condenser at A, and a negative resistance at B. Say $Z_0=(S_0p)^{-1}$, which makes the one extra q be $h=S/S_0$. Then, instead of the above-used unit impulsive function, we shall find that

$$u=\frac{he^{h(x+y-l)}}{\cosh hl}+\frac{2}{l}\Sigma\frac{(s\sin-h\cos)sx\,.\,(s\sin-h\cos)sy}{h^2+s^2} \qquad (145)$$

is the proper one to use.

§ 304. Returning to the more interesting case in which $Z_0=-Z_1$, treated in § 299, where (115) shows the proper unit impulsive function, let Z_0 be L_0p, indicating an inductance coil without resistance. The determinantal equation of the extras is a cubic, and the assumption of no resistance makes it manageable. Thus, (106) shows that

$$p^3=\frac{R}{SL_0^2}=g^3, \text{ say,} \qquad (146)$$

finds the three extra p's—that is, $p=g$, g_1, and g_2, where

$$g_1=g(-\tfrac{1}{2}+i\sqrt{\tfrac{3}{4}}), \qquad g_2=g(-\tfrac{1}{2}-i\sqrt{\tfrac{3}{4}}).$$

Also, in virtue of (146), we may write R/L_0p for q. So, by (115), the part of the unit impulsive function depending upon the extras is given by

$$\frac{R}{SL_0g}\frac{\epsilon^{Rz/L_0g}}{\text{shin}\frac{Rl}{L_0g}}+(\text{same with } g_1)+(\text{same with } g_2). \qquad (147)$$

The time factors to be introduced later are ϵ^{gt}, ϵ^{g_1t}, ϵ^{g_2t}. The part of u depending on the regulars is given by the first line in (115), omitting the $1/l$ term, however, because there is terminal earth connection.

Of the three terms in (147) only the first increases with the time. The two others unite to make a real function indicating oscillatory subsidence, but it is of a complicated mixed kind, because it depends on two inductances separated by the permittance of the cable. The full development need not be given.

§ 305. The same extra functions are, of course, concerned when the source is an impressed force. For example, let it be e at $x=0$. Equation (59), § 291, shows the V that results. Put $Z_0=-Z_1$ in it. Then

$$V=\frac{\{\sin-(Z_0s/R)\cos\}s(l-x)}{\{1+(Z_0s/R)^2\}\sin sl}e \qquad (148)$$

gives V in terms of e.

Specialise, by making $Z_0=R_0$, a resistance. Then

$$V=h\frac{(h\sin-s\cos)s(l-x)}{(h^2+s^2)\sin sl}e, \qquad (149)$$

where h denotes R/R_0.

Put $s=0$ to get the part independent of the time, and then develop by the expansion theorem (30), as in previous cases. The result is

$$V=e\left(1-\frac{x}{l}-\frac{1}{hl}\right)+\frac{e\epsilon^{h(x-l)}}{\text{shin}\,hl}-\Sigma\frac{2he}{sl}\frac{(h\sin+s\cos)sx}{h^2+s^2}, \qquad (150)$$

without the time factors. That is, it is the initial state, representing $V=0$ everywhere between $x=0$ and l, and at the terminals as well. This is because there is terminal resistance. In the summation, we have $sl=n\pi$.

We may verify the result by the conjugate property. Assume that

$$\frac{e}{hl}-e\left(1-\frac{x}{l}\right)=A_0\epsilon^{hx}+\Sigma A(h\sin+s\cos)sx \qquad (151)$$

Multiply by ϵ^{hx} and integrate along the cable to find A_0. Multiply by $(h\sin+s\cos)sx$ and integrate to find A. The results are as in (150).

I give this case for the sake of a result which will be useful a little later. It is got by differentiating (150) to x. We obtain

$$\frac{\epsilon^{h(l-x)}}{\text{shin}\,hl}=\frac{1}{hl}+2\Sigma\frac{(hl\cos+sl\sin)sx}{(hl)^2+(sl)^2}, \qquad (152)$$

which will be used in another problem.

§ 306. It will be seen from the preceding that the subject of abnormal Fourier series is quite a large one. We find that we require to use series that look like Fourier series, inasmuch as the wave lengths are the same as in real Fourier series, but that the complete set of normal functions includes extra functions of the type ϵ^{hx}, where h is a constant, real or complex, as the case may be, the number of such functions depending upon the terminal conditions. These abnormal series are merely special cases of the general series got previously by leaving Z_0 and Z_1 independent of one another. If any one of the electrical constants involved in these operators, which constants are real and positive in real problems, be made negative, we introduce something abnormal, because there is a reversal of Ohm's law, or of the law of displacement, or of induction, in some part of the electrical system concerned, and, as a

PHOTOGRAPHS OF THE ELECTRIC ARC.

The accompanying illustrations are the outcome of some photographs of the electric arc taken by Prof. J. Violle, and were exhibited by him at the Easter Exhibition of the Société Française de Physique. Having shown by previous experiments (*Comptes Rendus*, Vol. CXV., p. 1273, and *Journal de Physique*, Vol. II., p. 545, 1893) that the brilliancy of the crater was the same for currents between 10 and 400 amperes, Prof. Violle was anxious to make sure that it was the same with currents of 1,000 and 1,200 amperes. It was found to be rigorously constant. The photographs were taken very quickly with the objective "*fortement diaphragmé*," so that the blacks of the negative were far from saturated, an essential condition for accurate photometric comparisons. The two arcs—one of 1,000 amperes and the other of 10 amperes—were photographed one after the other on the same plate, which was afterwards developed all over in exactly the same manner.

Digitized by Google

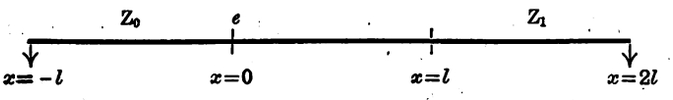
result, time functions, as ϵ^{pt}, occur in which p is positive. Some cases of this kind were considered by me in 1882, and earlier ("Electrical Papers," Vol. I.). The peculiarity of the cases above treated lies in the simplicity produced by reducing the wave lengths of the regular normal functions to be the same as in the original Fourier series. I think I have given sufficient information to enable any competent person to follow up the matter in more detail if it is thought to be desirable. It is obvious that the methods of the professedly rigorous mathematicians are sadly lacking in demonstrativeness as well as in comprehensiveness.

But it would be out of place to elaborate further in this work. I will therefore conclude the present remarks on abnormal series with the consideration of a very singular case indeed. In none of the previous cases did we cause the terminals to be nodes of the regular normal functions, or make $V=0$ terminally in them. In the following we shall do this.

Go back to (59), § 191, and make $Z_0=-Z_1$. This produces (148) above. So far it expresses V due to e at $x=0$ with any terminal Z_0, provided there is its negative at $x=l$.

Next, let
$$Z_0=\frac{R}{s}\tan sl. \tag{153}$$

This says that Z_0 is a cable identical with the one in question, or equivalent thereto, earthed at its end. We have therefore

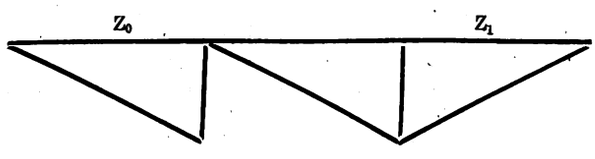


three cables in sequence, two of which are alike, extending from $-l$ to $+l$, with a negative cable added from $x=l$ to $2l$, that is, a cable in which the permittance and resistance are negative, without other change. This arrangement being in equilibrium, e is started and maintained constant. It is of little consequence to follow up the later effects. It is just at the beginning that we require the behaviour, so as to obtain the proper expansion of the initial state. The condition (153) reduces (148) to the very simple result
$$V=-\frac{\sin sx}{\tan sl}e, \tag{154}$$

which makes V permanently zero at $x=0$. This is highly anomalous. Expand (154) by the expansion theorem. The result is apparently
$$V=-\frac{ex}{l}-\Sigma\frac{2e}{sl}\sin sx\,\epsilon^{pt}, \tag{155}$$

where $\sin sl=0$. Now this is incorrect, because the initial state is $-e$, according to (155). There is something missing.

But there is some sense in it. For it makes the final current be $C=e/Rl$. By continuity, this, if existent, should be the current through all three cables. The corresponding state of potential is then as in the figure.



The zero potential at $x=0$ is accounted for. We may corroborate this by calculating the rise of potential in the cable Z_0 due to e, regarding the rest as a mere terminal arrangement. It will be found that the resistance operator of the two cables from $x=0$ to $2l$, reckoned at $x=0$, is zero, which is equivalent to a short circuit, so far as the cable Z_0 is concerned. So e establishes V in the Z_0 cable just as if there were an earth on the other side (the right side) of e.

After this partial explanation return to (154) and (155), where the state of the middle cable is in question. The resistance operator to the right is zero, but then the potential at $x=0$ is zero, so there is compensation. According to (155) a complete normal system of potential would consist of $\sin sx$ from $x=-l$ up to $x=l$, combined with $-\sin sx$ from $x=l$ up to $2l$. But it is easily to be seen that we cannot expand an arbitrary function in terms of these systems alone. For instance, let $V=f(x)$ (any function) from 0 to l, zero from 0 to $-l$, and $V=f(2l-x)$ from l to $2l$. The energy is zero, so the result of expansion by quadratures is zero.

It is certain that (155) is incomplete. And, in fact, we may ask, where are the abnormal functions necessitated by the negativeness of resistance and permittance in Z_1? The answer is to be found by seeing how $\tan sl$ in (154) arose. It represents $\sec sl\times\sin sl$, and $\sec sl=0$ is the equation belonging to the extra functions. But the roots of $\sec sl$, infinite in number, are at infinity. The normal functions to correspond are therefore unmanageable from being ungetatable. Their influence, however, is in full operation. For the failure of (155) proves that the sum of the whole of the missing functions required to make it represent the initial state truly is e. That is, we should have, initially,
$$0=e-\frac{x}{l}e-\Sigma\frac{2e}{sl}\sin sx, \tag{156}$$

where the first e is the sum of the missing terms.

§ 307. But to make this conclusion plainer, we should bring the roots at infinity to a measurable distance (like the abolition of that fraud 4π which has been purblindly inserted in the electrical equations), so that we can manipulate them. Take, then,
$$Z_0=\frac{R_0}{s_0}\tan s_0l_0, \tag{157}$$

instead of (153). The cable Z_0 is no longer an exact or equivalent copy of the middle one. Then (148) makes
$$V=\frac{(\sin-c^{-1}\tan s_0l_0\cos)s(l-x)}{(1+c^{-2}\tan^2s_0l_0)\sin sl}e, \tag{158}$$

instead of (154). Here $c=Rs_0/R_0s$ or $(RS_0/R_0S)^{\frac{1}{2}}$. The abnormal roots are now finite.

Let $V=U+W$, U being the part of V depending upon $\sin sl=0$, and W the extra part. Develop U in the usual way by the expansion theorem. We get (with $t=0$)
$$U=e\left(1-\frac{x}{l}-\frac{1}{cf}\right)-\Sigma\frac{\sin sx+c^{-1}\tan f^{-1}sl\cos sx}{\frac{1}{2}sl(1+c^{-2}\tan^2f^{-1}sl)}, \tag{159}$$

where f is the constant $(RSl^2/R_0S_0l_0^2)^{\frac{1}{2}}$. This U evidently reduces to the right member of (154) when $c=1, f=1$.

The development of W requires more care. The extra roots are given by
$$\tan^2s_0l_0=-c^2; \quad \text{or} \quad \text{than}^2q_0l_0=c^2. \tag{160}$$

Whether we take c or $-c$ to be than q_0l_0 is indifferent, provided we work consistently. Say, then, that
$$\text{than}\,q_0l_0=c, \tag{161}$$

or, which is the same,
$$\epsilon^{2q_0l_0}=\frac{1+c}{1-c}=g^2, \text{ say,} \tag{162}$$

which makes
$$q_0l_0=\lambda+in\pi, \quad \text{if} \quad \lambda=\log g, \tag{163}$$

provided c is less than 1. But if c is >1, then
$$q_0l_0=\lambda+i(n-\tfrac{1}{2})\pi \tag{164}$$

instead, where λ is the same real constant. The form assumed by W when expanded is, therefore, quite different in the two cases. At the point $c=1$ there is a jump, and special care is required.

Let us use (167), with $c<1$. Then
$$p\frac{d}{dp}\tan^2s_0l_0=-s_0l_0\tan s_0l_0\,.\,(1+\tan^2s_0l_0)$$
$$=-q_0l_0c(1-c^2). \tag{165}$$

The application of the expansion theorem to (158), so far as the extras are concerned, therefore makes
$$W=\Sigma\frac{2ce\epsilon^{qx}}{q_0l_0(1-c^2)(\epsilon^{2ql}-1)}. \tag{166}$$

In this, the relation between q and q_0 is $ql=fq_0l_0$, and in (163) n has to receive all integral values, positive and negative, including zero. The nth term of (165) pairs with the $-n$th to make a real function. But, owing to the exponential function in the denominator of (166), the resultant takes a

Digitized by Google

rather complicated form, which need not be given. It is sufficient for our purpose to see that if f is an integer, the denominator simplifies. We then get

$$W = \frac{2ce}{1-c^2}\frac{1}{g^{2f}-1}\Sigma\frac{\epsilon^{qx}}{q_0 l_0}; \qquad (167)$$

that is, by (163),

$$W = \frac{2ce}{1-c^2}\frac{\epsilon^{\lambda fx/l}}{g^{2f}-1}\left\{\frac{1}{\lambda}+2\Sigma\frac{(\lambda\cos+n\pi\sin)n\pi fx/l}{\lambda^2+(n\pi)^2}\right\}, \qquad (168)$$

where the summation is with respect to n, which has all positive integral values from 1 to ∞.

Comparing the last equation with (156), we see that hl becomes λ and x becomes fx. The quantity in the big brackets in (168) is therefore

$$\frac{\epsilon^{\lambda(1-xf/l)}}{\text{shin}\,\lambda}, \quad \text{or} \quad \frac{1+c}{c}\epsilon^{-\lambda xf/l}, \qquad (169)$$

by (163). This reduces W to

$$W = \frac{2e}{1-c}\cdot\frac{1}{g^{2f}-1}, \qquad (170)$$

provided f is an integer.

Let it be 1, *i.e.*, $RSl^2 = R_0S_0l_0^2$, then

$$W = \frac{e}{c}. \qquad (171)$$

Finally, $c=1$ makes $W=e$, as was to be proved.

We have proved that in the singular case of identity or equivalence between the terminal cable Z_0 and the middle one, when the extra normal functions apparently go out of existence, by the roots of the determinantal equation becoming infinite, they are nevertheless virtually existent, and must be allowed for in the expansion of the initial state.

In the more general case, in which there is not the equivalence mentioned, no such straining of the expansion theorem is needed. For instance, W in (168) may be tested in other cases in which f is integral, and be found to represent the negative of the U in (159). There is, therefore, no reason to doubt the equivalence of $-U$ with the more general form W in (166).

(To be continued.)

THE ELECTRIC ARC.

BY HERTHA AYRTON.

(Continued from page 748, Vol. XXXV.)

The Resistance Employed to Steady an Arc.

It is now possible to consider the influence on the arc of the E.M.F. of the generator, and of the resistance placed in circuit outside the arc. This may be done in two ways, graphically by means of Fig. 46, the curves in which are a reproduction of those in Fig. 33, with certain additions; and analytically by examining equation (4) (p. 420, *The Electrician*, July 26th) in conjunction with an equation expressing the relation between the E.M.F. of the generator, the P.D. between the ends of the carbons, the outside resistance in circuit, and the current flowing.

Since equation (4) applies only to silent arcs, it will be better to deal first with silent arcs by both methods, the graphical and the analytical, and then to take up the discussion of hissing arcs.

We might consider what would happen when any one of the four possible variables, the E.M.F. of the generator, the outside resistance, the current, or the length of the arc, was kept constant, and the rest varied; but for the present it will be sufficient to take the most important case, that of a generator of constant E.M.F. For this case applies to all mains supplying current at a constant P.D., since current flowing at a constant P.D. between the mains, when there is a certain fixed minimum resistance in the arc circuit, is practically the same thing as current supplied by a generator of constant E.M.F.

The graphical method is, perhaps, the easier to follow, and will therefore be taken first. Let P (Fig. 46) be a point on the axis of P.D. such that its distance from the axis of current represents the E.M.F. in volts of the generator supplying the current, and let P Q be a line parallel to the axis of current, so that the distance of any point on P Q from the axis of current will represent the E.M.F. of the generator, if it is constant for all currents. Then, if R_1 be a point on one of the curves, the distance between R_1 and the axis of current will represent the P.D. in volts used in sending the current through the arc, and R_1 S, the distance between R_1 and P Q, will represent the P.D. employed in sending the current through the outside resistance. Also, since P S represents the current flowing when that outside resistance is in circuit, the ratio of S R_1 to S P, which is tan R_1 P Q, represents this outside resistance.

If, then, with the given generator supplying the current, any line be drawn from P making an angle Q P R with P Q, and cutting the curves at various points, the positions of those points will represent the relation between P.D. and current in arcs all having the same outside resistance in circuit—namely, that represented by the tangent of the angle R P Q. We may, then, for convenience sake, call such lines as P R_1 Y resistance lines.

There are three possible ways of altering the conditions of the arc when the E.M.F. of the generator is kept constant, viz.:—

(1) The external resistance may be kept constant, and the length of the arc varied.

(2) The length of the arc may be kept constant, and the external resistance varied.

(3) Both the external resistance and the length of the arc may be varied together.

In the first case, since everything is constant except the length of the arc, lengthening the arc *must* mean increasing the resistance in the whole circuit, and consequently a diminution of current must follow on it. Similarly, shortening the arc must mean a diminution of the total resistance in circuit, and therefore an increase of current must follow on it.

In the second case, since everything is constant except the external resistance, increasing this must increase the total resistance in circuit, and therefore must diminish the current; while diminishing the external resistance must cause a diminution in the total resistance in circuit, and therefore must cause an increase in the current.

In the third case, the current may be made to vary in any manner that is desired, or to remain constant, by suitable variations of the external resistance and the length of the arc. But the sum of the effects of the variation of each of these must be the same as if each had been varied separately while the other was kept constant, so long as one of the variations does not cause the arc to be extinguished, thus making it impossible for the other to take effect after it.

While the external resistance can really be kept absolutely constant, the length of the arc cannot, for it is quite impossible, either automatically or by hand, to keep the carbons moving towards each other at exactly the same rate at which they burn away. Consequently what is *called* keeping the length of arc constant is really allowing it to become slightly longer than the desired length, and then bringing the carbons together till it is slightly shorter, so that the curve connecting time and length of arc when the length of arc was supposed to be constant, would be a zig-zag, not a straight line.

Similarly, what is called a constant current is not really constant, for it is impossible to lengthen or shorten the arc, and at the same time alter the resistance by exactly the right amount to keep the current constant. Hence there is a continual increase and decrease of current above and below the supposed constant value. Nevertheless it is possible to keep both length of arc and current constant within certain limits, which may be made very narrow by careful experimenting.

If we follow one of the resistance lines, P R_1 Y for instance, we shall see what happens when the external resistance is kept constant, and the length of the arc varied.

The first thing that strikes one about this line is that the curves for silent arcs above a certain length—viz., 6mm.—are not cut by it at all; that the curve for this length is touched by the line, while those for shorter lengths of arc are cut by it in two points, or would be cut in two points, if hissing did not intervene and terminate the curve. The two points at which

Digitized by Google

the line P R_1 Y cuts each of the curves for lengths of arc less than 6mm. are closer together the nearer the length of the arc is to 6mm., and we may consider that it really cuts the 6mm. curve at two points which are coincident. The fact of its not cutting the curves for longer arcs at all shows that no arc of greater length than 6mm. can be maintained by a generator with the given constant E.M.F. when a resistance represented by tan R_1 P Q is in circuit; in other words, 6mm. is the maximum length of arc that can be maintained under the given conditions of generator and external resistance.

The fact of the resistance lines cutting each of the curves that they meet at two points makes it appear as if, with a generator of constant E.M.F., and a constant resistance in circuit external to the arc, two widely different currents might be sent through two arcs of the same length. That is, apparently, under two precisely similar sets of conditions, two entirely different things may happen. This is, of course, absurd. Either the conditions cannot be precisely similar, or if they are, the two different currents cannot permanently flow. By tracing the course of events from the moment the arc is struck it is possible to find out which of these two hypotheses is justified by facts.

We know from experience that immediately after striking the arc, in the ordinary way, the current flowing is comparatively large, since the length of the arc is very small, and that if we lengthen the arc without altering the resistance in circuit, we diminish the current. Hence it is evident that if we want to follow the course of events after striking the arc, we must follow the line P R_1 Y from right to left, because in going from right to left it cuts the curve for each successive length of arc in points which show that the current diminishes as the length of the arc increases. For instance, following P R_1 Y (which corresponds with an E.M.F. of 68·88 volts and a resistance of 1·05 ohms) from right to left, we see that when the arc is 4mm. in length the current is about 18 amperes, when it is 5mm. the current is about 14 amperes, and when it is 6mm. the current is a little over 8 amperes. The right-hand points of intersection of the resistance lines with the curves are, then, those we are accustomed to find after striking an arc, and we know, therefore, that they are possible. Can the left-hand points also be obtained when the E.M.F. of the generator and the outside resistance are the same as for the right-hand points? is the question now to be answered.

In going from right to left along the line P R_1 Y, everything is perfectly easy till the arc is 6mm. in length, that is, till the resistance line is a tangent to the curve connecting P.D. and current. When this point is reached, however, trouble arises, for, since 6mm. has been shown to be the maximum length of arc that it is possible to maintain with the given resistance in circuit, and since the tendency of the arc is to lengthen, unless the carbons are brought nearer together at the very moment they have become 6mm. apart, the arc will be extinguished.

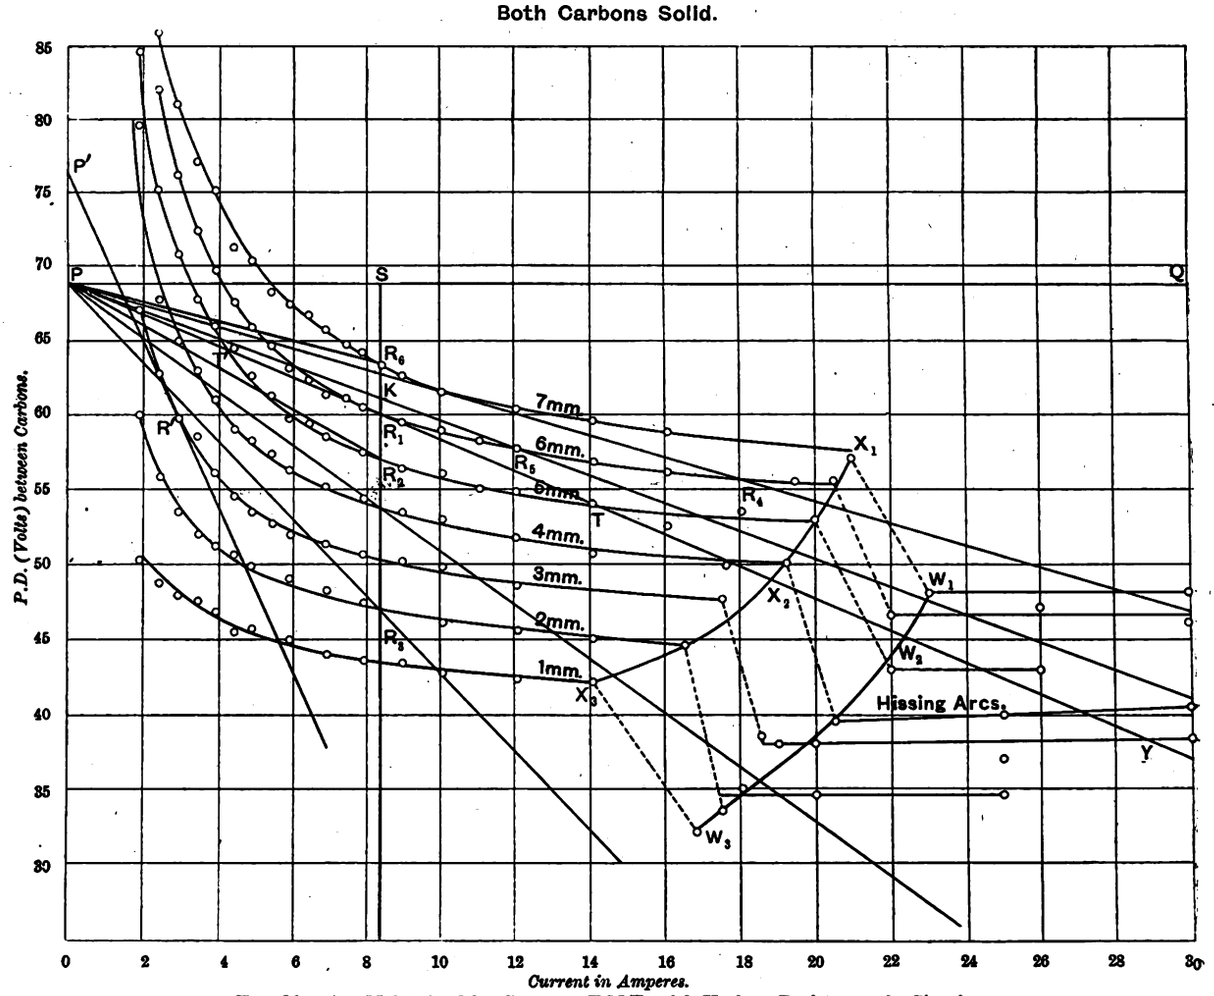


FIG. 46.—Arc Maintained by Constant E.M.F. with Various Resistances in Circuit.

It would, of course, be very difficult, if not impossible, to bring the carbons nearer together at the precise moment when their distance apart was 6mm., but supposing that done, the question arises, which course would the point of intersection of the resistance line and the curve for the shorter arc take; would it move to the right or to the left, should we get a right-hand or a left-hand point of intersection between the resistance line and the curve; or, in other words, would the current increase or diminish? There is not much difficulty in answering that question. It has already been pointed out that, if everything else remains unchanged, shortening the arc can have only one result: it must lessen the total resistance in circuit, and therefore lead to an increase of current.

Hence the point R_1 will move to the *right* when the arc is shortened, and it is thus evident that it is not possible to obtain a left-hand point of intersection between the resistance line and the curve by keeping the external resistance constant and varying the length of the arc.

Digitized by Google

It still might be possible, however, to get to a left-hand point of intersection by varying the external resistance and keeping the arc at a constant length. Let us see. We may suppose that the arc has been struck, that its length has been increased from zero to 6mm., and that a silent arc is being maintained with a current of about 20 amperes flowing. If the length of the arc be now kept constant the resistance will have to be increased, in order that we may pass along the curve for a silent arc of 6mm. As the resistance is increased the current will diminish, and the points of intersection between the resistance lines and the curve will be right-hand points, such as R_4 and R_5, till the resistance is represented by tan $R_1 P Q$, and the resistance line is a tangent to the curve.

When that moment is reached the resistance has of course gained its maximum value for a 6mm. arc, for if the angle $R_1 P Q$ were still further increased, the line $R_1 P$ would not meet the 6mm. curve at all. Hence, at this point, the arc could no longer be allowed to become even slightly longer than 6mm. before shortening it, as had hitherto been done, for it would go out directly its length exceeded 6mm.

Thus, the resistance must be diminished the moment the arc is 6mm. long, and the question again arises, Which way would the point R_1 go—to the right or the left? Would the current increase or diminish when the external resistance was diminished? This question is readily answered. We know that diminishing the resistance, and leaving all else unchanged, can only cause a diminution in the total resistance in circuit, and hence an *increase* of current, which will give us over again points on the curve to the *right* of R_1. It is, therefore, impossible to obtain the left-hand points of intersection between the resistance lines and the curves by varying the external resistance and keeping the length of the arc constant.

It remains only now to see if these points can be obtained by varying both the external resistance and the length of the arc at the same moment, and this seems the most plausible method of all. It seems so possible, when the resistance line is just about to become a tangent to the curve, to suddenly diminish the resistance and lengthen the arc at the same moment, so as to pass quickly through the critical point, and arrive safely at a left-hand point of intersection on the other side of it.

That this idea is fallacious is, however, easily proved by referring to three conclusions that have already been shown to be true. With a generator of constant E.M.F. to supply the current—

(1) Changing both the length of the arc and the resistance together can only have the same effect as changing each separately in quick succession, if the order of change be such that one does not extinguish the arc before the other can take effect.

(2) Changing the length of the arc alone can give only right-hand points of intersection between the resistance lines and the curves.

(3) Changing the resistance alone can give only right-hand points of intersection between the resistance lines and the curves.

From these three facts it follows that it is impossible to obtain left-hand points of intersection between the resistance lines and the curves by altering the external resistance and the length of the arc simultaneously, and it follows that there is no possible way of varying the conditions of the arc in such a manner as to obtain left-hand points of intersection between the resistance lines and the curves connecting P.D. and current.

Hence no points can be obtained on the curves connecting P.D. and current farther to the left than those which form the points of contact between the curves and the tangents drawn to the curves from that point on the axis of P.D. which indicates the E.M.F. of the generator.

The question arises, then, How can these left-hand points be obtained at all; how *were* they obtained? They were obtained as *right-hand points*, by using a generator with a much larger E.M.F. than that indicated by the position of P. It is, of course, obvious that all the points on the curves that are higher up than the line P Q must have been obtained with a generator of larger E.M.F. than that indicated by P; but what this investigation shows is that some of the points that are much lower down in the figure than the line P Q must also have had a generator of higher E.M.F. to produce them. The point for 2 amperes, for instance, on the 2mm. curve, although corresponding with a P.D. of only 58·5 volts, must have been found with a larger E.M.F. than 69 volts, which is indicated by the position of P, for the tangent from P to the 2mm. curve touches the curve at a point indicating a current of between 2 and 3 amperes.

On referring to Fig. 46, it is seen that a left-hand point of intersection of a resistance line and a curve—for example, the left-hand point T', where the resistance line $R_1 P$ meets the 5mm. curve—has the following property: If the E.M.F. of the generator be kept constant, and also the length of the arc, an *increase* of the resistance of the circuit corresponds with an *increase* of the current. Now, this is exactly the condition of the unstable solution that is obtained when a series dynamo, running at fixed speed, is in series with a set of accumulators of fixed E.M.F., the total resistance in circuit being also fixed.

For in such a case, as Dr. J. Hopkinson showed some years ago, there are three distinct values of the current possible, two of these corresponding with the dynamo charging the cells, while the third, which is very large and is negative, is produced when the magnetisation of the dynamo has been reversed, and the dynamo is helping the cells to discharge. Now, the smaller of the two positive charging currents is *unstable*, for it *increases* in value with an *increase* of the resistance in circuit, so that on the slightest change in the speed of the dynamo, or in the resistance in circuit, this unstable current is suddenly changed into the larger charging current, or into the very much larger discharging current.

Further, just as I have shown that a left-hand point in Fig. 46 may, for the same current and length of arc, be changed into a right-hand one by increasing the E.M.F. of the generator and the resistance in circuit, so it may be shown that Dr. Hopkinson's unstable point may, for the same current and the same set of accumulators, be changed into a stable solution by raising the speed of the series dynamo and increasing the resistance in circuit.

The impossibility of obtaining small currents without having a comparatively large E.M.F. in the generator and a large external resistance, explains a very puzzling circumstance that occurred in carrying out the experiments of which the curves in Fig. 46 are the result—one which many other experimenters must have noticed before me.

There were two dynamos at the Central Technical College, either of which it was convenient for me to use; one of these produced about 120 volts, and the other about 150 volts on open circuit. The first ran much more steadily than the second, which was driven by a single-cylinder engine; the former was, therefore, much better to employ in a general way; when, however, it was used for small currents and long arcs, the arc behaved in the most tricky manner, going out again and again for no apparent cause.

The reason of this is now obvious. The curves for long arcs are so nearly vertical in the parts for small currents, that the tangents to those curves at any of the points indicating small currents are very nearly parallel to the axis of P.D., and therefore intersect it very high up. It is this point of intersection, however, that determines the smallest E.M.F. that it is possible to have in the generator, and the smallest resistance that it is possible to have in the circuit, in order that a given current shall flow through a given length of arc. Thus, although, for the smallest current and longest arc I used, a P.D. of only about 86 volts was required for the arc itself, yet an E.M.F. of considerably over 120 volts was needed in the generator to enable the arc to be maintained at all with the given small current flowing. The remainder of this large E.M.F. had to be wasted in sending the current through the large resistance that it was absolutely necessary to have in circuit.

On page 401 of *The Electrician* for February 1st I showed that the resistance added to an arc lamp on a constant-pressure circuit fulfilled two distinct functions. The one, which was already well known, was to prevent an enormous current flowing when the arc was first struck, the second, which I do not think had been previously pointed out, was to render it possible for a solenoid placed in series with the arc to regulate its length. We now see, however, that *this resistance fulfils a third and entirely different function, for without some resistance being placed in the circuit external to the arc it is impossible to maintain a silent arc at all.*

Digitized by Google

Hence the resistance placed in series with an arc lamp "to steady the arc," as it is commonly said, fulfils the all-important function of making a silent arc possible.

In fact, an arc possesses this very curious property, hitherto unpublished, and indeed not thoroughly realised by myself until this summer, viz.: that, although a certain current of, say, A amperes flowing steadily through an arc of, say, l millimetres in length corresponds with a P.D. of, say, V volts between the carbons, the mere maintenance of this very P.D. of V volts between the very same carbons with the very same arc, of length l millimetres, is not a sufficient condition to ensure that the current of A amperes shall continue to flow.

As an example of this peculiarity, I may refer to the difficulty, alluded to on page 472 of *The Electrician* for February 15th, which I met with when experimenting on arcs with constant P.Ds. An examination of Fig. 46 shows that when, for example, a current of 11 amperes is steadily flowing through an arc 5mm. long, formed with solid carbons 11mm. and 9mm. in diameter, the P.D. between them is 55 volts. It might, therefore, be imagined that this current could be sent through such an arc with a dynamo compounded and run at such a speed as to maintain exactly 55 volts between the carbons with no resistance inserted between the dynamo and the carbons. Or it might be thought that this steady current of 11 amperes could be sent through this arc by means of, say, 29 accumulators when such a small resistance was inserted in the circuit that, with a current of 11 amperes, the accumulators maintained a P.D. of 55 volts between the carbons.

But when I tried this, and similar experiments of keeping the P.D. between the carbons constant, the arc always either went out, or the magnetic cut-out, set to open at 30 amperes, broke the circuit. The explanation of this is now clear, for what I was really endeavouring to obtain was a silent arc with a fairly *small* current, and a *small* resistance in circuit external to the arc; in other words, I was trying to obtain the *left*-hand point of intersection between the 5mm. curve and the resistance line, and this, as I have proved in the present communication, is impossible, a fact, however, which I did not realise ten months ago. Indeed, with a set of accumulators having an E.M.F. of about 58 volts and a small resistance in circuit, the only current that could flow steadily through a 5mm. arc between the carbons in question was a very large one far greater than 30 amperes. The value of this current would be known if we could find the intersection of the resistance line with the hissing part of the 5mm. curve at a point far off the figure to the right.

What has not, I think, been hitherto recognised, is the fact that, *in order that a given current may be maintained flowing through a given length of arc, there must be a minimum external resistance in the circuit which is independent of the E.M.F. of the generator.*

For example, whatever be the nature of the generator, the *least* resistance that can be placed in the circuit to send a steady current of 11 amperes through a 5mm. arc is that given by the tangent to the 5mm. curve at the point corresponding with 11 amperes. And on drawing this tangent to the 5mm. curve in Fig. 46, which was obtained, it must be remembered, with *both* carbons solid, we find that it corresponds with a resistance of 0·64 ohm.

This minimum resistance determines the minimum E.M.F. in the generator for each current and length of arc; for example, on continuing the resistance line just referred to for the 11-ampere 5mm. arc we find that it cuts the axis of P.D. at 62 volts. Hence a resistance exceeding 0·64 ohm must necessarily be placed in the circuit, and the E.M.F. employed must exceed 62 volts, although the arc requires a P.D. of only 55 volts. Similarly, although we see from Fig. 46 that a 12-ampere 3mm. arc requires a P.D. of only a little less than 49 volts, the preceding reasoning tells us that, with the solid carbons used, two such arcs could not be run in series off the ordinary constant-pressure 100-volt electric lighting mains, even if the supply pressure were kept absolutely constant at 100 volts. Or again, two 10-ampere 4mm. arcs could not be run in series off 110 volts constant-pressure mains, although each arc requires less than 53 volts with the solid carbons I used.

A resistance exceeding a certain minimum must in all cases be placed in the circuit to render it possible for the required current to flow, and this minimum resistance was so great for an arc of 7mm. and current of 2·5 amperes with the solid carbons I used that it made the minimum E.M.F. required more than half as large again as the P.D. used in sending the current through the arc itself, for I have calculated that the minimum E.M.F. was about 139 volts, while the P.D. needed by the arc was only 86 volts, as has been mentioned.

It may be seen from Fig. 46 that the compulsory minimum resistance outside the arc is greater—

(1) the greater the length of the arc,
(2) the smaller the current.

But the apparent resistance of the arc also increases with the length of the arc, and is greater the smaller the current, so that we arrive at this very curious fact: *When a silent arc is being maintained the smallest resistance that it is possible to have in the circuit external to the arc is greater the greater the apparent resistance of the arc.*

(To be continued.)

STREET LIGHTING BY ARC LAMPS.*

BY ANDRE BLONDEL.

(Continued from page 15.)

We ought not, then, to seek to make the illumination produced by a source, uniform, excepting on the condition that we leave a certain minimum quantity of superabundant light at the foot of the lanterns. We may consider it as necessary at these points to obtain an illumination of 10 lux, which permits reading easily, and we should give up the idea of uniform illumination unless we can give this relatively high illumination everywhere. Should the production of light be cheap enough for one to realise mean illuminations of 8 to 10 lux, one might seek for uniform illumination, but still it is necessary to remark that this uniformity should not be applied but to the resultant illumination of many lanterns and not necessarily to the individual illumination of each of them. It is to be feared, besides, that inconveniences will present themselves from the point of view of optical illusions that may be produced. Let us suppose, for instance, that the source has the form of a uniformly illuminated luminous sphere, which is approximately the case with diffusing globes, the luminous intensity produced in each direction being equal to the product of the apparent surface by its intrinsic brillancy, or following the same law of augmentation as I—that is to say, proportionally to $\cos^3 a$. We should then have sources of light which would appear more brilliant at a distance than close to.[21] This fact would completely upset the public, who would no longer be able to appreciate distances or understand the enfeeblement of the brilliancy of the globes when looked at closely.[22] Besides, if the illumination of the road is uniform—that is to say, I $\cos^3 a$ constant—the vertical illumination of cabs and passengers would increase proportionately to $\tan a$—that is to say, proportionately to the distance; which would produce a most strange effect. For all these reasons I believe that the desideratum of individual uniform horizontal illumination is perhaps Utopian, and, at any rate, the moment has not yet come to seek to realise it. In the present circumstances the most that we may demand in this way from the law of the distribution of each source is uniformity of the vertical illumination produced outside a cone formed by the rays at 45deg., while keeping to the interior of this cone the more or less superabundant light. Such a law of distribution is represented by curve II. of Fig. 16, which has for equation $I_\alpha \cos^2 a \sin a = \text{constant}$, from the angle of 45deg. Under these conditions we can be sure that a passenger, or an object that moves along a line joining two lanterns, will remain illuminated in

* From *Le Génie Civil.* Translated by Mr. John Heaketh.

[21] This is evident if the image on the retina is not a point, for the illumination is then proportional to the brilliancy of the object. When the image on the retina is reduced so far as to become a point, the quantity of light received by it varies proportionally to I_α, and in the inverse ratio of the distance from the eye to the object—that is to say, proportionally to $\cos^2 a$. As we suppose $I_\alpha \cos^3 a$ constant, we see that the apparent brilliancy increases proportionally to $\frac{1}{\cos a}$.

[22] It must not, however, be forgotten that the public, to appreciate any system of lighting, much more readily look at the globe than the ground, and believe all is perfect when the luminous source appears blinding. Although I mention this singular fashion of judging the things which I shall criticise later, it is not in the least necessary to take account of it in practice.

Digitized by Google

the most constantly uniform manner possible. It is very interesting to compare on this figure the three photometric curves corresponding to the uniformity of the one or the other of three illuminations. These three curves have been drawn with the assistance of the results of the calculations shown in Table IV., obtained on the supposition that it was desired to realise a light of 100 pyrs in the direction of the vertical. We thus see that for the vertical illumination a much less rapid increase of the intensity with the obliquity of the rays is involved than in the case of the two others.

TABLE IV.—*Table of Photometric Curves obtaining Uniform Illumination on a Horizontal Plane.*

Angular direction. a	I. Normal illumination. $Ia = \frac{100}{\cos^2 a}$	II. Vertical illumination. $Ia = \frac{100}{\cos^2 a \sin a}$	III. Horizontal illumination. $Ia = \frac{100}{\cos^3 a}$
0	100 pyrs	∞	100 pyrs
7°30′	101	730 pyrs	102
15°	106	113	110
22°30′	107	306	126
30°	133	266	153
37°30′	158	260	199
45°	200	282	282
52°30′	269	340	443
60°	400	461	800
67°30′	683	739	1,862
71°34′	1,002	1,057	3,174
75°	1,494	1,542	6,069
80°	3,322	3,378	19,200
90°	∞	∞	∞

We must not forget, besides, that beyond a certain distance we should in all cases renounce uniformity of illumination, so as to escape losing too much light by absorption of the rays sent to a distance. On the other hand, we cannot limit, for instance, by the aid of reflectors the rays in a direction below that of the horizon, for if we did this the lanterns of a street or a boulevard would not be visible, except at a very short distance, while it is absolutely necessary that the greatest number possible should be seen simultaneously, so as to obtain a good effect of perspective; but as it is not necessary that they should play an appreciable lighting part, we may reduce to a very small value the intensity of the rays sent towards the horizon. The best theoretical curve of the individual distribution in a word will take the form OABCD (Fig. 16) which blends with the curve of equal vertical illumination in the middle, and with a circle at the angle of 45, where the illumination is superabundant. None of the sources of light actually in use agree, even roughly, with this desideratum. It cannot even be realised, excepting by optical devices, to which I shall refer later. I shall examine, to begin with, the indirect methods of *uniformisation* which may admit of the bad distribution of actual source being palliated—that is to say, choice of a favourable height and a convenient distribution of the lamps; and we shall see later how we may bring into use the rays sent above the horizon, of which we do not at this moment take account.

HEIGHTS OF LAMPS.

The sources of light actually employed, and in particular the electric arc with or without globes, all present in their polar curves a critical direction corresponding to a relative maximum illumination.[23] The consequence is that we make the illumination produced by each lantern uniform at the same time that we increase its minimum value by augmenting the height. The clause of a contract which imposes a certain minimum horizontal illumination leads, then, to the employment of greater elevations if we consider it alone, more especially in the case where arcs under clear globes are employed. It is to the too exclusive consideration of this minimum, without doubt, as much as to the desire to shun dazzling effects, to which it is necessary to attribute the infatuation that people had, in the early days of electric lighting, for very high lanterns. These have more especially been in favour in the United States,[24] where they have attained a height of 30 metres and more. In Europe they have been used but little; I only, for instance, think at Milan. In France we have never regarded this system with favour, and though in 1888 M. Eiffel proposed to illuminate the capital by great lighthouses placed on towers 300 metres high, conveniently spread about, his idea has not been taken seriously by competent authorities. The only example we have had of high lanterns in Paris—in La Place du Carrousel—was sufficient to make both the public and the engineers forsake them. The great pillars—25 metres in height—which are fixed on this square are, happily, very soon to disappear. In short, the uniformity of horizontal illumination is not attained under these conditions, excepting at the price of the following inconveniences: Firstly, a part only of the flux emitted below the lamp falls on the roadway and the bottoms of the houses; the rest is sent too high to serve for anything else but to draw shadows on the surrounding buildings. Secondly, the least haze or mist absorbs an enormous number of rays before they reach the ground. This last reason has been sufficient to force the Belgian State railways to lower the porches of the railway station of Schaerbeck (Nord), of which the lamps became useless in case of fog.[25] Thirdly, even in the absence of mist and in streets without trees and straight, where one can consider as useful all the lower hemispherical flux, the total surface illuminated increases with the height, and in consequence the mean illumination, calculated in the manner indicated before, diminishes. It is the same *à fortiori* for the maximum illumination. We tend, then, towards uniformity, but the uniformity of mediocrity. We may show this more clearly by a consideration of Figs. 18 and 19. These represent the values of the horizontal illumination on the

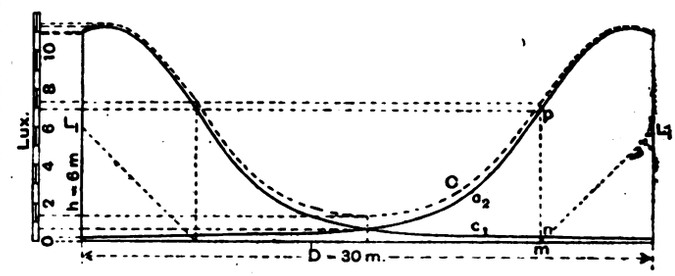

FIG. 18.—Two 10-ampere continuous-current arcs, under opal globes placed 6 metres high.

ground between two equal lights, of which the law of distribution is known. Fig. 18 applies to arc lamps of 10 amperes under opaline globes placed at a height of 6 metres, and Fig. 19 to the same lanterns placed at double that height (12 metres). The distance between them remaining the same, D equals 30 metres. Fourthly, the reduction of the useful effect is far more important still in that which concerns the vertical illumination, for the more one raises the lanterns the more they tend to badly illuminate the promenaders. It is to this effect that we must attribute the greater part of the bad apparent illumination realised on the Place du Carrousel, and this itself will be sufficient to proscribe high pillars They are not useful except for the lighting of yards, railways, or of docks, where it is necessary to escape the effects of contrasts. I have, however, sometimes praised the employment of very high lanterns on certain public places,[26] and this disposition may be justified in the case where it is a narrow place completely

surrounded by high houses.[27] The light which strikes the façades is not then altogether lost, but to a great extent reflected. It is no longer the same where the space is very large and incompletely closed. The example of the Carrousel which I have quoted proves this sufficiently. I also believe that in this case there was a

[23] We shall see examples of this in curves to be given later.

[24] Notably at Detroit, Alleghany, Cleveland, Los Angeles, &c., where the "pillars" are veritable towers, carrying many lamps, from whence is derived the expression "tower-lighting."

[25] Weissenbruch, *loc. cit.*

[26] M. Palaz notably, gives 10 to 20 metres as heights for arcs of 10 to 18 amperes.

[27] This case arose at Brussels, where M. Wybauw was able to very satisfactorily light La Grande Place by two lanterns suspended at 15 metres high.

I am particularly indebted for these interesting returns to the goodness of the engineers, Messrs. Monmerqué, Quintin, De Joukovsky, C. Cervi, Vermehren, Kirschner, Rothenbach, Uppenborn, J. Christie, W. Arnot, McCormick, J. P. Barrett, J. Harper, Fevrier, Dalichampt, Irly, J. Hesketh, H. F. Proctor, A. W. Ranken, and E. Price, to whom I wish here to express my sincere thanks.

reason for lowering the lanterns, without, however, descending below 8 or 10 metres and getting off by losing in uniformity. Besides, as we have seen higher up, the employment of opaline globes favours this. I have been able to see an example of this in the beautiful Newsky Perspective at St. Petersburg, but the height of 10·70 metres adopted on this road is the maximum admissible from the æsthetic point of view, and would not be justified on our straight boulevards. We gain equally in employing lower lanterns by a greater facility in up-keep when the lamps are fixed. Thus actually the height of 10 metres is not exceeded in public ways even abroad, as the figures of Table V., taken in Germany, Italy, &c., show. We see that in France we have long since adopted lower heights than the mean—heights which, however, appear good in their effect.[28]

In Paris, on the boulevards, the lanterns are 4·95 metres, or 5·95 metres with very variable distances from 25 to 50 metres. The current is 10 amperes. On the Avenue Clichy, much less lighted, the heights are 4·95 metres to 4·45 metres, with the same current and distances of 50 metres.

With the lamps actually in use—that is to say, with arc lamps in opaline globes—these small heights tend, it is true, to reduce the value of the minimum horizontal illumination. M. H. Maréchal has shown in particular that in the Avenue de Clichy the minimum illumination of the roadway falls from 0·37 lux to 0·18 lux only by the mere substitution of lamp-posts of 4·45 metres for those of 4·95 metres, which result is shown in the diagram of comparative illuminations, Figs. 20 and 21. But this peculiarity does not apply so much to the vertical illumination. We may besides reduce it either by artificially modifying the law of distribution of the rays of the actual lamps by the methods indicated later, or by distributing the lanterns in a more appropriate manner. In any case actual experience seems to establish empirically that it is necessary to confine oneself within the limits of 5 to 10 metres; 6 and 7 metres are the heights most common in France. If at Munich they have been able to adopt the higher limit of 10 metres it is only because the avenues are certainly smaller and not planted with trees, and because they employ movable lamps.

DISTRIBUTION OF LAMPS.

The method of distribution of electric lamps naturally depends on the length, importance, and the traffic on the roads to be lighted. First, if the length is not very considerable, the most advantageous solution, and the best from all points of view, consists in placing the lanterns on the axial line. This is the disposition most generally used to-day. Berlin, Milan, Havre, Toulouse, Nantes, Munich, Cologne, Vienna,[29] &c., and even Paris on part of the great boulevards, furnish beautiful examples of this. If we remember that in the interval between two lanterns the individual illuminations are added together, we see that in general we may adopt for lamp-posts a distance between them at least equal to the width of the street, unless the illumination at n falls below the value allowable upon the footpaths at a and b (Fig 22.). To roughly proportion the power of the lamps to the width of the streets it is sufficient, then, after having been given the maximum height of the lanterns, to choose a strength of current such that the horizontal illumination calculated for the point a from the curve of horizontal illuminations of the arc under its globe, shall attain the fixed minimum value, then to distribute the other lamps at such distances that the same horizontal and vertical illuminations shall be attained or exceeded at the points $n\,n'$. The illumination at $a\,b$ will be then a little higher than the limit. This rule, which is the most rational, can evidently not be followed when the street is too narrow, and when one has to consider the question of expense. For the smaller streets 25 metres may be regarded as a minimum below which we scarcely go as a general rule. Besides, in the case of narrow streets, the diffusion by the frontage plays a very important part, and renders an exact arrangement of the distances between the lanterns useless.

In the case where no refuges exist in the centre of the roadway, and where recourse cannot be had to suspension by chains, we are forced to adopt a solution much inferior to the preceding one, and to arrange the lanterns zig-zag alternately on each footway (Fig. 23). The minimum illumination will then be at a point about the middle of the distance A C, and the distance may be regulated according to the minimum illumination sought to be obtained. The quantity of light distributed remains almost the same as in the preceding case, but it is not so well utilised.

The fronts of the houses send back a part (0·2 to 0·5) of that which they receive; but if we take an avenue which is planted we may, on the contrary, consider as almost altogether lost the light

[28] This choice depends principally upon the way in which the cleaning is done. The use of a ladder naturally limits the height.

[29] A singular arrangement of lamps has been tried at Vienna, in the employment of two lamps hung from the same chain. This solution appears to have little to recommend it from any point of view, and it does not appear to me to be one which will be imitated.

Digitized by Google

received by the trees situated in the immediate proximity of the lamps, although it does contribute in a certain degree, however, to the general effect by making the trees better distinguishable. This distribution has been adopted in a great number of cities in Europe and America—in Paris, in the Avenue de Clichy; in very important streets, such as the Rue Royale in Paris, Unter-den-Linden in Berlin, &c.

In certain cases where an intense illumination is desired we may be brought to unite the two distributions into the *quincunx* form by adding lanterns on the refuges to those on the edges. This is

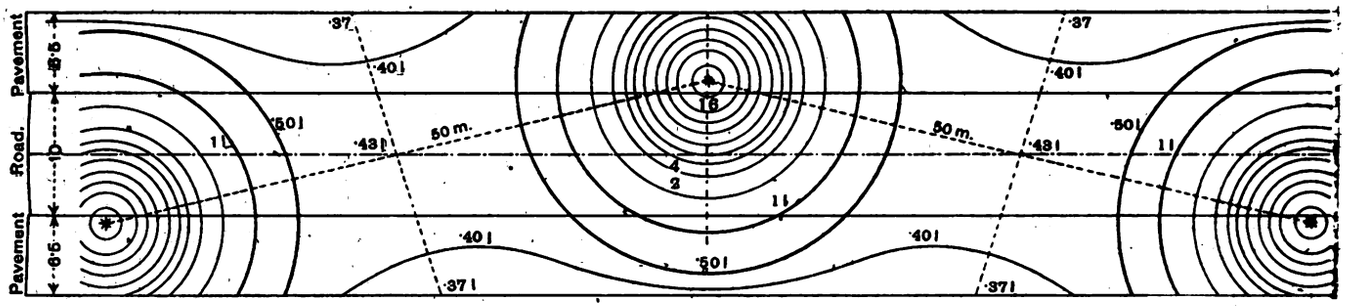

FIG. 20.—Plan of illumination with 10-ampere continuous-current arcs under opal globes, Avenue de Clichy. Height of lamps 4·95 metres. (Figure taken from *L'Eclairage à Paris* by M. H. Maréchal.)

Berlin, in the Leipzigerstrasse; in New York, in all the streets excepting the Fifth-avenue.[30]

In wide streets we can obtain a much better distribution for an equal expense of energy by reducing the current to one-half, and doubling the number of lamps, as is shown in Fig. 24. The triangular arrangement is not to be recommended, except in narrow streets, and when we cannot have recourse to transversal suspension.

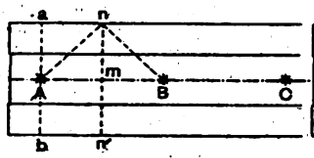

FIG. 22.—Distribution of lamps in straight line in the axis of a street. (Grand Boulevards: Section Edison).

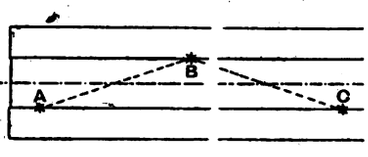

FIG. 23.—Distribution of lamps in triangle, alternately on each footpath (Avenue de Clichy).

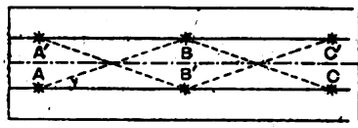

FIG. 24.—Distribution of lamps in rectangle on the two footpaths.

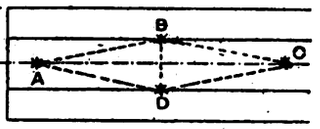

FIG. 25.—Distribution of lamps in *quincunx*, according the mixed system of the Grand Boulevards (Section Popp).

As in general it has been the practice up to the present to use lamps taking 10 amperes and over, the distribution shown in Fig. 24—that is, in rectangle—is not yet applicable, excepting to the distribution adopted in Paris on the main boulevards (Section Popp, Fig. 25), and also in a slightly different form in La Rue Royale (Fig. 26), where the illumination on the roadway, according to M. Maréchal, obtains the extremely high mean value of 3·40 lux. The distribution in *quincunx* lends itself particularly well to the illumination of large squares or gardens. When the

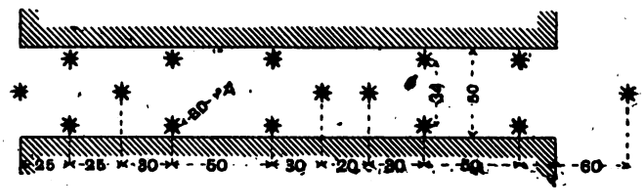

FIG. 26.—Distribution of Lamps in the Rue Royale.

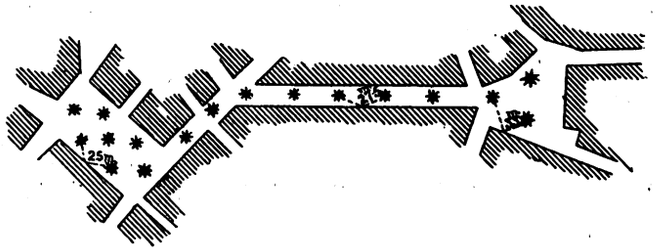

FIG. 27.—Scheme of Distribution of Electric Lamps for the Publi Lighting of the town of Lille.

scheme elaborated by MM. Gavelle, Mougy, and Robard, of which we reproduce the plan here in Fig. 27, is completed, we shall see an interesting and very successful example in the illumination of La Grand Place at Lille. In New York all the Fifth-avenue is illuminated in this manner with double lanterns. It is one of the finest examples of lighting by arcs; but this arrangement, which greatly multiplies the number of lamps, has been up to the present quite the exception.

(To be continued.)

[30] In this last city, the arrangement of houses into "blocks" in a perfectly regular chequered pattern has allowed an absolutely uniform method of distribution to be adopted. The avenues lighted are 30 metres wide, and are crossed every 60 metres by transverse streets 18 metres wide. In the avenues, the lamps are placed at the crossings, and alternatively on the right and left footpaths. In the transverse streets the length of the blocks of houses varies from 18 metres to 23 metres, and the lamps are spaced about every 90 metres.

PHASING TRANSFORMERS.*

BY CHARLES S. BRADLEY.

The polyphase motor is so good as to need but very little, if any, improvement. One of the important links to round out the art seems to be the phasing transformer, so that we can take a single-phase alternating current and convert it into polyphase of any desired number.

I have chosen for my work the conversion of single-phase to three-phase, because the three-phase motors which we have been able to construct give us very much less trouble than the two-phase. In a series of experiments I have found that the two-phase motor would run at a number of speeds, especially when supplied with current from a phasing transformer. I supposed the trouble arose from harmonics, but of this I am not certain. The three-phase motor never has given us any of this trouble. These experiments, however, were carried out before the transformers had been refined,

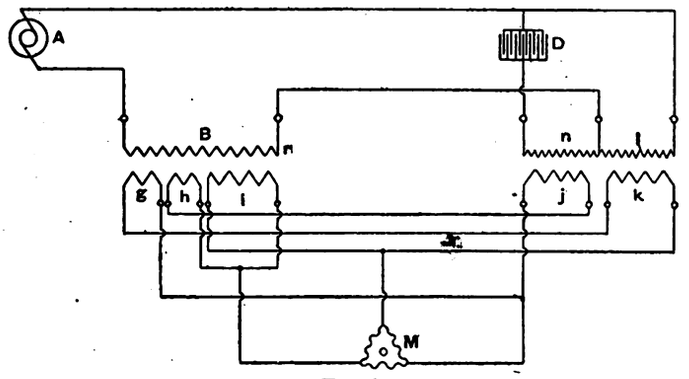

FIG. 1.

and, now that we are getting more perfect results, I think it is very probable that we could return to the two-phase motor, and get much better results than when first tried.

The following is a description of an arrangement of condensers and cores to produce polyphase and single-phase alternating currents. Many different arrangements of condensers and inductances have been tried, and all have failed to keep their phases at a working relation, except the one I am about to describe.

A diagram of the phasing transformer and connections with the generator and motor will be found in Fig. 1, A being the generator, B the simple section of the transformer, D the condenser, and M the motor; r, primary of the simple section of the transformer; n and l, primary of the compound section; g, h and i, secondaries of the simple section of the transformer, and j and k, secondaries of the compound section. The primary of the simple section of the transformer is in series with the compound section and condenser.

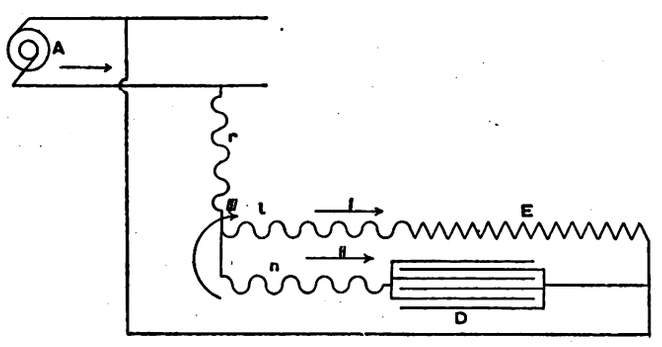

FIG. 2.

By the proper adjustment of capacity and inductance, the magnetic flux in the core of the compound section is approximately 90deg. in phase behind the simple section; then, in order to get three phases from the two, I resort to resultants in the secondaries: g and k constitute one phase, h and j a second, and i the third.

The essence of this invention rests in the arrangement of the compound section of the transformer and condenser. There are, undoubtedly, several ways of explaining the theories involved in this device, and most people would prefer the mathematical description, but, as I did not hit upon the invention by that method, I shall follow in the explanation the same method of reasoning as I used to arrive at the result.

* Abstract of a Paper read before the American Institute of Electrical Engineers, New York, September 25th.

In order to explain the theory involved in this, refer to Fig. 2, in which A is the generator, E the inductance, D a condenser or capacity; l and n represent the leads to the inductance E and to the capacity D. If the generator is generating an electromotive force in the direction of the arrow (Fig. 2) a current will flow through the lead l and the inductance E, as represented by the arrow I., and through n into D, in the direction of the arrow II. During the rise of the electromotive force through the machine from zero to the top of the wave, the current will flow in parallel into or through the inductance E and the capacity D. As soon as the wave of the electromotive force commences to decline the condenser will begin to discharge, and the current flowing from it will be in the direction of the arrow III, Fig. 2. Also, at the same time, the inductance will discharge its energy by a current in the direction of arrow III., so that the current represented by arrow III. is delayed by 90deg. Thus we see that the current represented by arrow III. will be lagging in its time period considerably behind that in the lead r. Now, if we wind the lead l and the lead n upon an iron core, as shown in Fig. 3, in opposite directions, and of the same number of turns, and have the inductance E bear a proper relation to the capacity D, so that the currents represented by arrow I. and arrow II. shall be equal, no magnetic flux will be produced in the

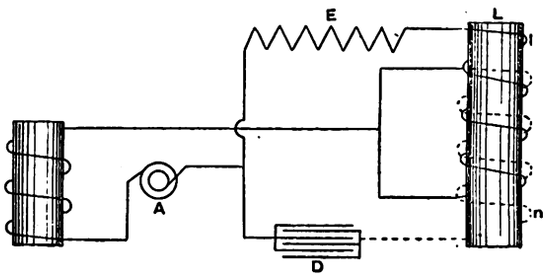

FIG 3.

core during the rise of the potential of the machine, but during the fall of the electromotive force of the machine and during the discharge of the inductance and condenser which is represented by arrow III. (Fig. 2), the currents flowing through n and l will be in series and flowing in the same direction; consequently, the magnetic flux will be approximately 90deg. later than it would be if charged directly from the machine.

I have represented in Fig. 2 a section of lead by r, and it will now be clearly seen that the current in the lead r will have a phase difference from the combined or resultant phases in the leads l and n. Furthermore, a current in the lead r will be in lead of the electromotive force of the machine, because the inductance and the condenser, previously described, cut off the flow of the current before the machine has reached the zero point, and when the lead r is placed upon an iron core, as shown in Fig. 3, it has a tendency to lag, which counterbalances the lead and leaves the main-line current somewhere near the phase with the electromotive force of the generator.

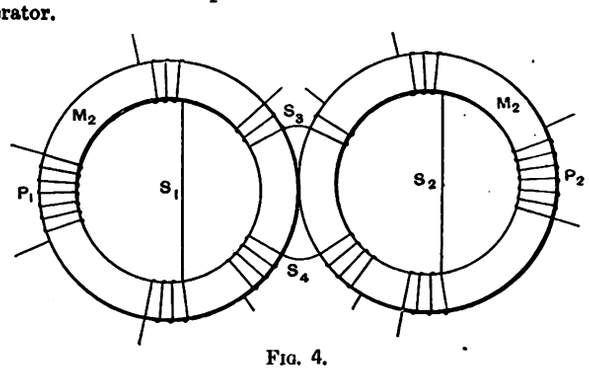

FIG. 4.

Refer now to Fig. 3, where the leads l and n are wound in opposite directions, and completely interlaced upon the iron core L. The lead r is here wound upon the second iron core, which constitutes the primary of the simple section of the transformer as shown at B, Fig. 1. In reducing to practice and applying the transformer to an induction motor, we find that the inductance E can be dispensed with, as the apparent inductance produced by the motor furnishes all the lag necessary; and it will be noted that in Fig. 1 the extra inductance which we used in our first experiments is left out of the combination. The lead from the simple section of the transformer, it will be noted, goes to the centre of the compound section. This diagram does not represent the true condition of the compound section, for the winding n and l are together, or, as before mentioned, interlaced upon the core. The magnetic flux in the two sectior of the transformer are approximately 90deg. apart.

D

Digitized by Google

The secondaries are, therefore, wound each partially upon the two cores, so that the three resultant phases may be produced from two, this being in accordance with Mr. Fred. S. Hunting's invention for changing two phases to three. For the description of this I will quote Mr. Hunting's own words, and the plan is in Fig. 4.

"If P_1 and P_2 represent two primary circuits supplied respectively with alternating currents differing in phase, or disposed in any other suitable manner so that the fluctuating magnetic impulses developed in the cores M_1 and M_2 differ in time, then the secondary currents developed in circuits S_1 and S_2 will differ in time period. If other circuits, as S_3 and S_4, be so arranged that part of their convolutions will enclose one magnetic core and part another, there will be developed in these circuits a resultant current due to the combined action of both magnetic cores, and this current may be given any desired degree of phase displacement with reference to the current in primary coils P_1 and P_2, accordingly as the number of convolutions surrounding the respective cores are varied. For example, if, as shown in circuit S_4, an equal number of convolutions is placed around each core, then there will be developed in circuit S_4 a resultant current having its phase half-way between the phase of current in coils P_1 and P_2. If the number of convolutions on the two cores vary in the proportion of three to two, and be joined together as indicated by the coils S_3, the resulting current produced by these coils will be closer in phase to the current flowing in P_1 providing the larger number of convolutions be placed as indicated in the diagram upon the magnetic core controlled by coil P_1. Thus, by varying the relative proportions of the two coils inclosing the two magnetic circuits, a resulting current of any desired phase displacement with reference to the phase of coils P_1 and P_2 may be developed. It will thus be seen that by means of two magnetic circuits or cores in which magneto-motive forces differing in phase are developed, we may produce any

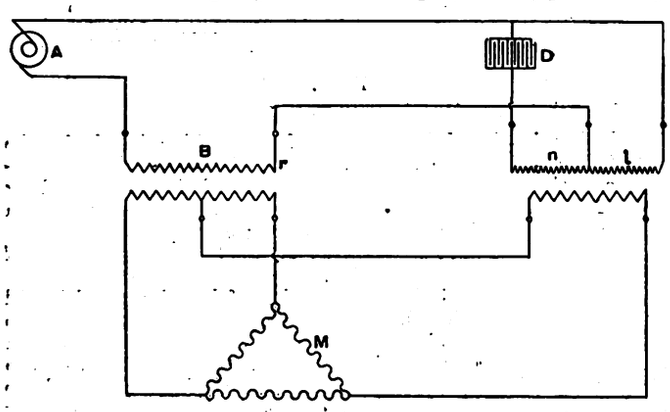

FIG. 5.

desired number of currents of differing phase, and may produce a definite degree of phase displacement, and the resultant current may in any case be shifted closer to the phase of magneto-motive force in either core by increasing the inductive influence of said core upon the circuit carrying the resultant current. In the organisation shown in the diagram we will have four secondary currents developed from the primary coils P_1 and P_2, and assuming that the currents flowing through these coils differ in phase, all of said secondary currents will differ in phase."

Mr. Scott's invention for changing two phases to three may also be used, and is shown in Fig. 5. Making the resultants in this manner by means of the secondary windings contributes also to steadiness of phasing. If desired, two secondaries having a proper two-phase relation may be used on the motor.

The experimental work, in which I have been greatly assisted by Messrs. Hulse and Chapman, has occupied a long time, and has passed through a great many stages. The results represent a great deal of patience, and we have chased the phases from zero to 180deg., back and forth, until there is a well-worn path between these two points, but finally we have a set of beautiful results. This motor gives powerful starting torque, and it gives me pleasure to show it to you here in operation.

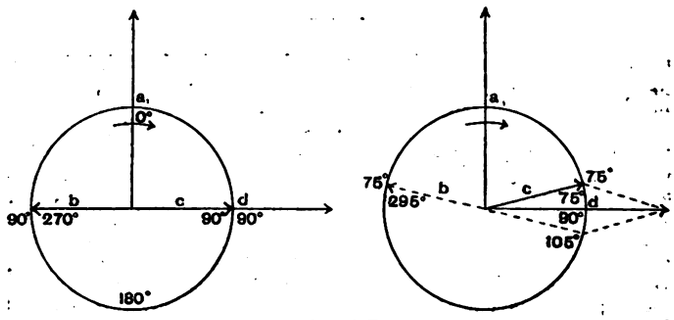
I want to bring to your attention one feature of the compound coil used in combination with the condenser, which will be found in Figs. 6 and 7. If we suppose a direction of motion, as shown by the arrow and the current in the condenser branch, leads by 90deg., which is represented at b, and the current in the inductance branch lags by 90deg., as indicated at c, and the wires carrying these currents are wound in opposite directions upon the core, we shall have a resultant current which is represented by extension d. Increase of load changes the phase relation of the individual branches, but not the resultant secondary, and this is explained by reference to Fig. 7, where a 75deg. lead and a 75deg. lag are represented by the respective branches, and as the branches are wound in opposite directions we find that when b is turned over it becomes a lag of 105deg., and the resultant of 75deg. and 105deg. again produces 90deg. lag, and the value again represented by the extension d; the value of the current is slightly less, but its resultant phase is the same as is represented in Fig. 6. This explains the steadiness of phasing which we are able to obtain.

The power factor is found to be very good, it being 82 per cent. even at light loads, and the probability is that we shall have very much better results upon larger-sized transformers.

The condenser in this combination fills two very important functions, first assists in the phasing and second prevents the lag upon the line. This arrangement does not prevent the idle currents flowing in the motor circuits and the secondaries of the phasing transformer, and we find in small motors with the high period of 140 cycles that the apparent energy in the motor circuits is sometimes two and one-half times the apparent energy in the main line. The capacity of condenser for a one-half horse-power motor when 1,000 volts are supplied to the transformer is about 2·4 microfarads. Our condenser for this size, without connections, occupies a space of a cube four inches on each side, and capable of enduring 3,000 volts, or a factor of safety of four, as the voltage on the condenser is about 700. Of course, it will be understood by those familiar with the designs of induction motors that it is impossible to design a small motor with small power factor, as the air-gap necessary for mechanical construction has to be so large in proportion to the size of the motor.

Many attempts have been made by placing the condenser in direct connection with motors to produce rotary fields, but have so far been attended with little success. As the trade requires the motor to be of comparatively low voltage, which calls for a large capacity in the condenser, and as the output of the condenser of a given capacity is proportional to the square of the voltage, it will be seen how advantageous it is to place the condenser in combination with the primary of the step-down transformer.

The curves obtained of the electromotive force and current were were all of true sine form. The current for this work was obtained



FIGS. 6 and 7.

from a 75-kilowatt Slattery alternating machine. This machine has a surface winding on the armature, and, therefore, gives practically a sine wave. Just what the transformer may do on all the various dynamos that are in the market, giving all sorts of complex waves, it is difficult to say with our present experience, but so far as we know now, the transformer tends to smooth out all the irregularities.

While the principal use for this device at present seems to be the application of polyphase motors to single-phase lighting systems, many new ones undoubtedly will be found. It may seem bold to think of applying this to long-distance trolley railroads, but I am hoping to have it done. It is much more simple to have one trolley wire with track return than to have two trolley wires, which would be required by the direct application of polyphase systems. A large amount of power requires either a large current or high voltage, in order that the resistance of contact of whatever device is used to make connection to line need not be too great. As viewed at present, it seems as if the alternating current must be used for this work. If so, and unless the traffic is extremely frequent, it will take many more transformers, if they be placed along the line, than if the transformation is made upon the car or locomotive, because the transformers along the line having no trains or cars near them would be idle. If the voltage is stepped down on the car or locomotive, it is just as economical to do it by the phasing transformer, with the exception of the added weight of condensers, which for a 1,200 H.P. locomotive will be about two tons, and this is not of consequence on so large a power.

A brief description of the motor may be in order, although it does not belong strictly to this subject. We met with much difficulty in developing a motor for so high a periodicity as 140 cycles. It is necessary to keep the density so low, and it is always such a temptation to try to get all the power from a given piece of apparatus, that they are always heating much more than they should. With a large number of poles and slots, we found that any use of wide bars in the armature was out of the question, for

Digitized by Google

the eddying currents in the copper were too serious. *We also looked for difficulties which we never found.* At times we thought the heating was due to higher harmonics produced from the phasing transformer; but the fact is we never found any, unless it was in the experiments upon the two-phase motor. The rotary field of the motor is the exterior or stationary part, the secondary constituting the armature. The armature is composed of two sections, or practically two armatures end to end upon the same shaft, one of the armatures having a low-resistance winding, and the other a comparatively high resistance; the field is placed over a high resistance for starting, and shifted by means of a lever over the low resistance, when it has nearly attained speed. Of course this arrangement is for securing the starting up of the motor, and has nothing to do with the phasing transformer, and the motor might haverings for connecting the starting resistance to the armature and operate quite as well. The sliding of the field gave trouble, as the air-gap has to be small, and the play at the sides allowed the armature to strike against the field, and when a tight fit was made, which would work easily when cold, it would stick fast when the motor rose in temperature; the writer therefore decided to give it quite a clearance at these points, and give it a guide at the bottom of the field. This being central and comparatively thin, the expansion is not sufficient to cause sticking.

THE SURFACE CONDENSING PLANT AT THE NEWCASTLE AND DISTRICT COMPANY'S ELECTRIC LIGHT WORKS, NEWCASTLE-ON-TYNE.*

BY WILLIAM CROSS.

In 1892 the Newcastle and District Electric Lighting Company (Limited) decided to put down an independent surface condensing plant for the purpose of economising the consumption of steam, and as this plant differs to some extent with ordinary practice a short description may prove of interest.

The generating plant for which the above was designed consisted of two Parson turbo-motors, each of which, when running at full load and at 4,500 revolutions per minute, gave about 250 effective horse-power. These motors were supplied with steam at 140lb. pressure. The motors are designed to expand the steam about 150 times, thus giving a theoretical terminal pressure of 1lb. It was therefore obvious that an air-pump of ordinary construction could not maintain a vacuum nearly perfect enough to be of any service.

The situation was a somewhat difficult one, the point at which the condensing plant had to be fixed being 90 yards and the floor level 36ft. above low water springs in the river Tyne, which was the only available source from whence the water necessary for condensation could be obtained. It was, moreover, a point of special importance that the plant should be capable of running continuously for very long periods without stoppages for repairs or adjustments. The surface condenser was required to have 1,500 sq. ft. of cooling surface, and the pumps, &c., had to be made of suitable size for dealing with plant of such capacity. Owing to the height the condensing water would have to be lifted and the great length of the suction pipe, it was considered desirable to keep the condenser and pumps as low down as possible, and in view of the continuous running required, to keep the engine on the floor level, so as to be well in view and easily accessible.

The tandem compound pumping engine is carried on beams over the top of the shaft, whilst the condenser and pump are placed at the bottom, the pumps being connected to the rocking beam of the engine with wooden spear rods. The shaft is 10ft. in diameter, and from the bottom of it a drift 260ft. long, and of a cross-section of 4ft. 6in. by 4ft. 6in. is driven to the river, which it meets at about low-water level. Down the drift run two cast-iron pipes, each 12in. in diameter, one being the suction and one the return. These pipes are continued well into the river, the suction pipe being fitted at the end with a short length of flexible hose, with wind-bore and float so arranged as always to keep the extreme end well clear of the mud.

The surface condenser is 4ft. 6in. in diameter and 9ft. 8½in. long between tube plates, and contains 790 brass tubes ¾in. in diameter, giving a cooling surface of 1,512 sq. ft. The exhaust steam is brought to the condenser by light galvanised wrought-iron pipes, about 2ft. in diameter.

The engine is a tandem compound, on Kingdom's system, designed to run constantly at 60 revolutions per minute, having two cylinders 6½in. and 11½in. by 9in. stroke. There is no intermediate gland, a corrugated piston rod working through a long bush being used instead. There is only one slide valve, which is cast hollow, the exhaust from the high pressure passing through the back of the valve and into the low pressure; there is, therefore, only the slide spindle gland exposed to high-pressure steam, a point of importance in view of the long runs required. On the upstroke the corrugations of the rod constantly entering the bush tend to check any leakage of steam, and this they effect most completely, whilst on the down stroke the bottom of the high pressure and the top of the low pressure are in connection through the slide valve, and any leakage past the rod is a matter of unimportance. The rocking levers are double-ended, and are connected to the cross-head by links in the usual manner; the outer end of the levers drive the circulating pump of 1ft. 6in. stroke. Nearer to the fulcrum is attached the spear rod of the cold water pump, which is 9¼in. stroke, and at the inner end of the lever is the air pump spear rod, of 1ft. 6in. stroke. There are two flywheels on each end of the crank shaft, so that all strains are symmetrically distributed. The engine is controlled by a Tangye governor, but this is only intended to come into play in case of a spear rod breaking or a pump missing its water. The cold water pump is an ordinary ram pump, 4in. by 9¼in. stroke, taking the water delivered by the air pump, and delivers against a head of about 50ft. into a feed-water tank in the boiler room. It is driven by a light spear rod made of wrought-iron tube.

The circulating pump is double-acting on the constant-pressure system, which has the advantage of diminishing the number of valves required, and doing away with any valves in the bucket. This pump is 1ft 6in stroke, the bucket being 1ft 2in, and the ram 10in. in diameter; it is estimated to deliver 550 gallons of water per minute at 60 double strokes. The valves are of the ordinary india-rubber disc pattern, and are arranged so as to be very easy of access. The pump draws only on the upstroke; on the down stroke it delivers all the water to the top or ram side, but that as the ram is one-half the area of the bucket, one-half of the water is displaced and delivered into the condenser; on the succeeding upstroke the second half is delivered. The delivery is therefore practically constant, whilst the suction is intermittent. The velocity of water through the valves is 5ft. 6in. and in the suction pipe 3ft. 6in. per second. To prevent the shocks in the suction pipe, due to the intermittent flow, an air vessel of 11·25 cubic feet capacity was fitted. The water, after being forced through the tubes of the condenser passes back to the river through the second or exhaust 12in. pipe already mentioned, the effect of this being that the head is balanced by the suction of the delivery, and the work on the pumps very considerably reduced. As already mentioned, so high a vacuum was required that an air pump of ordinary construction could not be expected to deal with it, and one of special construction had to be constructed.

In an ordinary air pump the clearances are so large as compared with the volume swept by the piston that at very high vacuums the vapour is never compressed sufficiently to attain the atmospheric pressure *plus* that required to lift the valves, consequently on the next outstroke the vapour simply expands again and fills the barrel without any suction having taken place. It was therefore decided to break up the compression of the vapour into stages, so that the compression in any one cylinder would be but small, and the difficulty mentioned would not arise.

Having now briefly described the plant, it only remains to give the general results. A few difficulties were experienced at the first, but these were easily overcome, and the plant has been working continuously ever since. It generally runs for about six months on end without stopping, and practically without attention of any kind. Though only a part of the plant works into the condenser, the results so far have been very satisfactory. The cost of coal (at the same price per ton) per Board of Trade unit has dropped nearly 50 per cent., and the cost of water about 70 per cent., as taken over six similar and consecutive months in each case, a saving sufficient to pay the whole cost of installation in about three years, and this result would have been still more favourable had it not been for the unavoidable expense of the shaft and drift. Surely these figures are worthy of the attention of the owners of the numberless high-pressure non-condensing engines in this district, and who are in most cases much more favourably placed as regards site and facilities for obtaining condensing water than in the present case.

* Abstract of Paper read before the North-East Coast Institution of Engineers and Shipbuilders, Newcastle-upon-Tyne.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-day) FRIDAY, November 8th.

PHYSICAL SOCIETY.

5 p.m. Meeting at Burlington House. Papers to be read:—(1) "The Magnetic Field of any Cylindrical or Plane Coil," by W. H. Everett. (2) "The Latent Heat of Volatilisation of Benzene," by Mr. Griffiths and Miss Marshall. (3) "The Comparison of Latent Heats of Volatilisation," by Prof. Ramsay and Miss Marshall.

TUESDAY, November 12th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Address by Sir Benjamin Baker, the President, and presentation of medals, premiums and prizes awarded at the close of last Session.

Digitized by Google

The Electrician.

The Oldest Electrical Journal (1861—1878.)

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny.
Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The Rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	Year.	Half-Year.	Quarter.
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.

(Post free, payable in advance.)

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to* **4** *p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. *Vol. II. is in preparation.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.

VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free, 8s.

VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. 93 original illustrations, handsomely bound price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. SNELL. 10s. 6d.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free 8s.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

"THE ELECTRICIAN" PRIMERS. In Two Volumes. Price: Stout paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

THE WORK OF HERTZ. By Dr. O. J. LODGE. Price 2s. 6d.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. [*In preparation.*

SPECIAL NOTICES.

With this week's number of "THE ELECTRICIAN" is issued (Gratis) a Supplement Sheet of "Photographs of the Electric Arc." Complaints of non-receipt should be promptly made to the Publisher.

Last week's number of "THE ELECTRICIAN" commenced Vol. XXXVI. and contained (Gratis) the Index to Vol. XXXV.

ELECTRIC *v.* GAS MOTORS AT BRIGHTON.

To propel a girder-built vehicle weighing some 60 tons, and running on four submerged rails, at a velocity of about six miles an hour, through a depth of some 15ft. of sea water in an indeterminate state of agitation, will be a unique feat of engineering. So original, indeed, is the principle that, although the Brighton and Rottingdean Seashore Electric Tramroad Company purpose to put it into execution, they confess to the vaguest ideas as to the amount of power which will be required. According to their present plans, it is intended to equip the aforesaid 60-ton car with two 30 H.P. electric motors, and it is believed that these will suffice. At the same time, it is admitted that the data to determine this provision of power are of the most meagre nature. Though it may be impossible to state the maximum which will be required, it is not altogether difficult to fix a minimum limit. Two 30 H.P. motors will be sufficient, we think, only if each motor is capable of developing very much more than its rated power for a considerable time—perhaps, indeed, for the whole run. Ordinary tramcars running on well-conditioned rails require at least 1 H.P. per ton of gross load, and this provision is often exceeded, even on tracks where there are no stiff gradients or curves. With rails and wheels almost constantly submerged in sea water, and in altogether an indeterminate condition beneath many feet of saline fluid, with a girder stage drawn rapidly through a considerable depth of water, and with the stress which must arise from the currents and waves

Digitized by Google

impeding the vehicle, we should be disposed to estimate that a minimum of 80 H.P. would be required, and it would not surprise us if onoccasion the power should exceed double that figure.

It was intended at first to run this perambulatory pier by power supplied from a secondary battery. Whether or no this was feasible from an engineering point of view, it is not surprising that Mr. MAGNUS VOLK, the plucky promoter of this extraordinary scheme, together with those associated with him, should have come to regard the use of storage batteries as being commercially impossible. There is no good in demonstrating an engineering possibility if it is an assured commercial failure; so Mr. VOLK decided to abandon batteries, and to supply his vehicle with power by means of a trolley. As will be seen in another column, this decision has met with severe opposition from the Brighton Town Council. Plenty of objections were raised. It was urged that the trolley poles would be a danger to boats; that the wires would obstruct the "beautiful view"; and the general objections were advanced that the submerged rails would be a stumbling block to bathers; that the chalky "rock" in which the foundations of the line are laid might go the way of the sand on which a foolish man once builded his house; and that Brighton might be left with an ugly mixture of abandoned poles and wires if the scheme by any chance resulted in failure.

The Borough Electrical Engineer, having been requested to advise the Town Council in this matter, expressed himself in favour of the use of gas engines and compressed gas, whilst admitting the advantages of the trolley system. Now, gas-driven cars have nowhere become an established success, unless where cars of quite moderate weight are used. In this country they have more than once been tried, and in every case have been abandoned after a few weeks, or at most months, of experimental running. There are seemingly endless difficulties with them. In a vehicle moving through the sea, there would be perhaps no lack of jacket water; but the gas engine, even on cars not exceeding one-tenth of the weight of the proposed Brighton vehicle, has proved itself unequal to the development of a good starting effort—an especially necessary provision in this case—and unable to tackle in a satisfactory manner the variations of load and the changes and reversals of speed. The gas engine must be kept continually running at a fairly even rate, and all manipulation of the car must be done through the agency of gearing. Clearly, this type of motor is quite unsuited to the requirements of Mr. VOLK's novel and ponderous car.

But to what do the objections to the trolley system really amount? It has been said that bathers may be troubled by the hidden submerged rails. Will not, then, a line of trolley poles serve excellently well as a warning of the lurking danger? The outcry is also made that boats may be capsized by the poles. In daylight the poles will be visible, and at night it is not likely that strangers will venture to land at the base of a precipitous cliff. A pier or a groyne would be far more dangerous; and if the existence of pier lights is urged as a safeguard, we may add that such lights are not impossible on a line of trolley poles. With the prospects of success of this novel tramway we are not now concerned, nor with the general construction of the line and its remarkable car. But, conceding for the sake of argument that everything else about the system is in order, we have every confidence in recommending the use of the trolley for this particular job. Any element of structural weakness, commercial failure, or injury to the amenities of the Brighton foreshore, which this tramway may chance to develop, need not, we feel sure, arise from the use of the trolley system.

REVIEWS.

Armature Windings of Electric Machines. By H. F. PARSHALL and H. M. HOBART. (New York: D. Van Nostrand Company. 1895. London: "The Electrician" Printing and Publishing Company.)

Except the prehistoric Dredge this is the largest book electricians have ever had published for their benefit. The authors state at the outset that "it was concluded the only feature of the multipolar dynamo requiring special study was that of the armature windings," and they therefore proceed to give a vast amount of attention to the combinations and permutations of these windings. No one need now be at a loss to know exactly in what order to complete the circuit round the armature, when he has once decided on the general type of winding to be employed. But further study must be given than we have found possible before the information will be forthcoming—which is the best winding for any given multipolar ring or drum. This book gives ample information as to the order and disposition of the armature conductors, but it does not give with any sufficient clearness comparative information as to the results in practical working to be obtained from these several arrangements. Seeing how much greater the experience of large multipolar dynamos has been in the United States than in this country, English electricians cannot but feel grateful to the authors for placing before them at least a portion of the wisdom of the West. The authors were hampered at the outset "by the intervention of certain circumstances contingent to their position in an industrial concern," and from the absence of information of the greatest importance to designers it is probable that the restrictions were only partially removed. We must confess we do not share the authors' opinion that there is no other question than that of armature windings requiring special study, or rather we consider that in the question of armature windings is involved a number of allied questions on which by no means the last word has been said.

Some doubt is cast upon the efficacy of the Sayers device, of which a short description is given with a diagram. So far as we are aware, this device has never been applied to multipolar machines having other than the ordinary parallel winding with cross connections or multiple brushes. A question well worth consideration is whether that device is not specially applicable to multipolar machines having series winding, seeing that in these latter the question of collection is one of increased difficulty.

It must be 12 or 14 years since Prof. Perry invented the series armature winding for multipolar dynamos, and it is now nearly five years since Mr. Kapp in a Cantor Lecture first gave publicity to that form of the multiplication table known as an armature winding table. But series windings have never become popular, indeed they have probably not been very carefully studied in this country. In the United States large multipolar machines have been made in considerable numbers both for traction and for lighting. According to English ideas the multipoling has been carried to excess in many cases, but at least a great deal of experience must have been yielded as to the effects of different arrangements of armature windings. Some of the results of this experience are indicated in the large volume under consideration, and we are sure that designers of dynamos will turn its pages over with the object, in the first place, of finding at once what the authors have to say on this matter. They will find that before they can get much information they must familiarise themselves with some novelties in the shape of expressions and symbols, and then, armed with these weapons, proceed to a careful attack on the book, gradually finding out that there is a great deal more in it than they at first supposed. They will probably at the commencement of their studies be disposed to consider the diagrams and tables need not go quite from "twice one" to "twelve times twelve," but will probably come later on to appreciate the comfort of having all this in print in one book. They may also, sometimes, feel that no great harm would have been done in description of windings by the omission of passages such as the following: "It could be connected so as to give one-third as great a terminal electromotive force, by joining the three elementary

Digitized by Google

groups, of which each winding is formed, in parallel, instead of in series," but will find numerous instances in which the meaning is so much less obvious that they will be glad to have had the temporary relief.

The diagrams of armature windings number 129, all except two or three being full page, and as the book is quarto it will be evident that clearness has been given a first place—the descriptions face the diagrams, still further facilitating the task of tracing the connections and the reasons for their very numerous variations.

The last 70 pages or so consist of winding tables, giving the pitch for various numbers of conductors on armatures having various numbers of poles.

In conclusion, we wish to recommend this book as a collection of diagrams of armature windings, but must point out that it is not—and probably was not intended to be—a complete treatise on armatures. The general and particular knowledge necessary to properly use these diagrams in practice must be sought elsewhere.

The welcome accorded this book will be all the heartier from the fact that the first-named of the authors is now, and has for some time been resident in England, and engaged in applying here the knowledge and experience gained in the United States.

W. M. M.

Die Lehre von der Electrizität und deren Praktische Verwendung. By T. SCHWARTZE. (Leipzig: J. J. Weber. 1895.)

Electricity, with its innumerable branches, is a wide and far-reaching subject, but not too wide for this book; it embraces everything. Everything, theoretical and technical, from the foundations of dynamics to dynamo machines, is treated of more or less fully, and the only work left to the bewildered reviewer is to point out which subject is more and which less full.

The book is divided into three parts: General Physical Principles; Electrical and Magnetic Phenomena; Electrotechnics. The first part starts with a dissertation on fundamental units. Here mass is treated with the utmost contempt, and has to give place to force, "for we have nothing further to think of if we lay force aside." Mass is finally dismissed with the following words: "Mass is objective only in so far as it refers to space; all other properties are intuitive. Mass is therefore an intuitive form of space, *i.e.*, energy." These ideas, applied to the law of Coulomb, produce the following varieties: Line force, surface force and volume force, with respective dimensions $M L$; $M L^2$ and $M L^3$. These and the resulting dimensional formulæ are delightfully simple—when one gets to them, but the way to them leads through a valley of darkness; here, for instance, is one of the stumbling blocks we found there: "Space is defined as a field of force of mass, relatively incompressible, highly endowed with self-induction, capable of motion in transverse oscillations, and similar to a rigid body."

These elementary principles having been set on a satisfactory basis, we come to chapters on physical fields of force, oscillations, the composition of forces and rotation. Each is a treatise in itself, dealing with the whole range of its subject very concisely, but yet fully enough to show how exceedingly complex these matters are, when only considered from the right point of view.

The author begins the second part with a long discussion on electrical units and their dimensions; he gives Maxwell's dimensional formulæ with their later modifications, and also applies the dynamical ideas we have already mentioned to the formation of an improved system. The next chapter is devoted to electrostatics, especially to static potential, which is defined by the dimensional formula $M^2 L$. Then follows a well-arranged chapter on the various propositions of Gauss, Coulomb, Poisson and Green, deducing in conclusion a general formula for potential energy. Chapter XI. forms a splendid example of compression; the whole subject of specific inductive capacity, with its relation to the refractive index of light and various molecular properties, is run through in four pages of German—say one page of English. A student at this rate would become a first-class "theoretician" in a week! And a practician too, for suddenly, after pages of formulæ, we light on Sprague's instructions for setting up a tinfoil condenser, followed by three methods of measuring and comparing condensers. Constant current is the next subject. Ohm's law, after much discussion, is shown to be a consequence of Joule's; the next paragraph contains a deduction of Joule's law from Ohm's. Finally electrolysis, like everything else, is considered as a "force-working;" we read of an "overgoing force-ray-bundle" between the electrodes.

In the chapter on magnetism the author is fairly in his element; it is a thoroughly theoretical and dimensional chapter. It starts by showing the earth's magnetism to be a consequence of oscillations of the mass-centre, and finishes with remarks on metripolar, megapolar and brachypolar magnets. The author accounts for the attraction and repulsion of unlike and like poles by the action on one another of ether currents, due to each pole disturbing the equilibrium of the system. Chapter XVI. is an excellent exposition of electromagnetism, containing values and curves of magnetisation and hysteresis for the different kinds of iron, and a good deal on the windings and fields of electro-magnets. In the next chapter self and mutual induction, with their influence on alternate currents, are dealt with very thoroughly. The second part concludes with a survey of Hertz's and Elihu Thomson's experiments.

The third part, of 100 pages, calls for no special remark. It treats in the usual form of measuring instruments and measurement in general. The fullest information is given as to how the instruments ought to work, and how the various methods ought to give the required results; practical details, of course, a well-regulated German student leaves to the laboratory assistants, and would be out of place here.

It is a striking book. Its object—we learn it, luckily, from the preface—is to harmonise the fundamental principles of physics with the teaching of Faraday and his successors. But what is especially striking is the length of the words; setting quality aside, "Massengeschwindigkeitsaeusserungen" will be found hard to beat in point of quantity.

THE MAGNETIC FIELD OF A RECTANGULAR COIL.

BY PROF. G. M. MINCHIN, M.A., F.R.S.

The calculation of the value of the magnetic potential or force produced at any point in space by a rectangular coil of given length, breadth and depth is a matter of considerable difficulty. Of course, strictly accurate mathematical calculation is not practically necessary, since no coils in use are of an exact rectangular form.

In the following Paper we shall show how to calculate practically the component of magnetic force parallel to the axis of a coil of any dimensions at any point in space, and also the value of the potential due to any flat rectangular coil. A few numerical examples will be added by way of illustration.

In *The Electrician* for September 6th we have an accurate expression for the potential at any point in space due to a current of strength i flowing in any plane rectangular circuit, viz.:—

$$\frac{V}{i} = \sin^{-1}(c_1 c_2) + \sin^{-1}(c_2 c_3) + \sin^{-1}(c_3 c_4) + \sin^{-1}(c_4 c_1), \quad (1)$$

the notation of which is explained in the Paper referred to. We shall now put this expression into another form. In Fig. 1, *The Electrician*, September 6th, let the sides A B, B C of the rectangle be $2a$, $2b$; let α, β be the co-ordinates of Q with reference to the principal axes of the rectangle at its centre; then, taking the term $c_4 c_1$ in (1) as typical of all we have

$$c_4 c_1 = \frac{(a+\alpha)(b+\beta)}{\sqrt{\{z^2+(a+\alpha)^2\}\{z^2+(b+\beta)^2\}}}. \quad (2)$$

As we are about to calculate the value of V for any flat coil, such as that represented in Fig. 4 of *The Electrician* for September 27th, we shall suppose that we are now dealing with the individual rectangle $a\,b\,c\,d$ in that figure. The sides of A B C D in that figure being $2a$, $2b$, the sides of $a\,b\,c\,d$ are $2(a+x)$, $2(b+x)$; hence we write $a+x$ for a and $b+x$ for b in (2), and thus we have, putting $a+\alpha=p$, $b+\beta=q$,

$$c_4 c_1 = \frac{(x+p)(x+q)}{\sqrt{\{z^2+(x+p)^2\}\{z^2+(x+q)^2\}}}. \quad (3)$$

If we put

$$x+\tfrac{1}{2}(p+q)=X\,;\quad z^2+\tfrac{1}{4}(p-q)^2=h^2\,;\quad \tfrac{1}{2}(p-q)=k, \qquad (4)$$

this becomes

$$c_4 c_1=\frac{X^2-k^2}{\sqrt{(X^2+h^2-2k^2)^2+4k^2(h^2-k^2)}}$$

$$=\frac{X^2-k^2}{\sqrt{(X^2-k^2+z^2)^2+4k^2z^2}}. \qquad (5)$$

This term is typical of the others. Thus, to get $c_1 c_2$, we simply change α to $-\alpha$ in (5); to get $c_2 c_3$, change α to $-\alpha$ and β to $-\beta$; and so on.

Now, in (5), let $X^2-k^2+z^2=2kz\tan\phi$. Then, if $\sin^{-1}(c_4 c_1)=\psi_{41}$, we have

$$\sin\psi_{41}=\sin\phi-\frac{z}{2k}\cos\phi, \qquad (6)$$

in which, for convenience, we may omit the suffix from ψ, understanding that there will be four angles—ψ_{12}, ψ_{23}, ψ_{34}, ψ_{41}—corresponding to the several terms in (1).

Let R^2 be written for X^2-k^2; then we have the equations

$$R^2+z^2=2kz\tan\phi, \qquad (7)$$

$$\sin\psi=\sin\phi-\frac{z}{2k}\cos\phi. \qquad (8)$$

Now the value of V at the point P, due to the flat coil represented in Fig. 4 of *The Electrician*, September 27th, is obviously given by the equation

$$V=\frac{i}{h}\int(\psi_{12}+\psi_{23}+\psi_{34}+\psi_{41})\,dx, \qquad (9)$$

where h is the diameter of the wire, the limits of x being 0 and $m\,m'$, the breadth of the coil. Obviously $dx=dX$, so that

$$V=\frac{i}{h}\int\psi\,dX, \qquad (10)$$

where the integral is to be taken for each of the four gnomons $A'q'qApp'$, $qq'B'm'mB$, $mm'C'n'nC$, and $nn'D'p'pD$. Taking the first of these gnomons, to which ψ and X, taken as above, apply,

$$\int\psi\,dX=\psi.X-\int X\,d\psi, \qquad (11)$$

the right-hand side being taken from the point p to the point p' in the figure referred to. We now proceed to show how $\int X\,d\psi$ can be approximately evaluated. For this purpose we shall form a curve whose radius vector is X and polar angle ψ. To do this, eliminate ϕ from (7) and (8), and we obtain

$$\sin\psi=\frac{R^2}{\sqrt{(R^2+z^2)^2+4k^2z^2}}, \qquad (12)$$

which gives

$$R^2\cos^2\psi=z\sin\psi\{z\sin\psi+\sqrt{z^2+4k^2\cos^2\psi}\}. \qquad (13)$$

From this equation we proceed to construct R, and thence X. Take any two rectangular axes, Ox, Oy, Fig. 1; take $OZ=z$, $Ok=k$, $OK=2k$, and $OL=ZK$; on OZ and OL describe two semicircles. Now draw a line OQ making any angle, ψ, with Ox, and meeting these circles in N and S; take $Os=OS$ and on the line OQ take Q so that $ZQ=Zs$; at Q and N draw perpendiculars to the line OQ meeting Ox in q and n; on Oy lay off OT equal to the mean proportional between On and Oq; and finally on OQ take

$$OP=Tk.$$

Then $OP=X$, and the locus of all the points P obtained by drawing a series of positions of OQ is the curve kAPB represented. This, then, is the curve in which the radius vector OP is X and the polar angle is ψ; it is thus easily constructed, and were it not for the single operation of finding OT as the mean proportional between On and Oq the construction of the curve would be very rapid.

Now the expression $\int X\,d\psi$ between any two points, A, B, on the curve is the sum of the successive small steps perpendicular to the radius vector described by a point travelling along the curve from A to B; and this can be read by a planimeter, or, with sufficient accuracy, by actual measurement and summation of a few of the steps.

There is another simple mode of constructing this curve AB, which is as follows: at K draw a perpendicular to ZK, meeting yO in C; on yO produced through O take $OA=\frac{1}{2}ZC$; on AO take $AF=\frac{1}{2}OZ$; describe a parabola whose focus is F and vertex A; let any line, OQ, meet this parabola in H; on Oy take T such that OT is the mean proportional between ON and OH; then, as before, $OP=Tk$.

The calculation of the potential of any flat rectangular coil at any point in space requires, therefore, the tracing of four curves of the above kind, in all of which the circle on OZ is the same, and the circle on OL alone varies, because k varies, the four values of k being $\frac{1}{2}(m+n+\alpha+\beta)$, $\frac{1}{2}(m+n-\alpha+\beta)$, $\frac{1}{2}(m+n-\alpha-\beta)$, $\frac{1}{2}(m+n+\alpha-\beta)$.

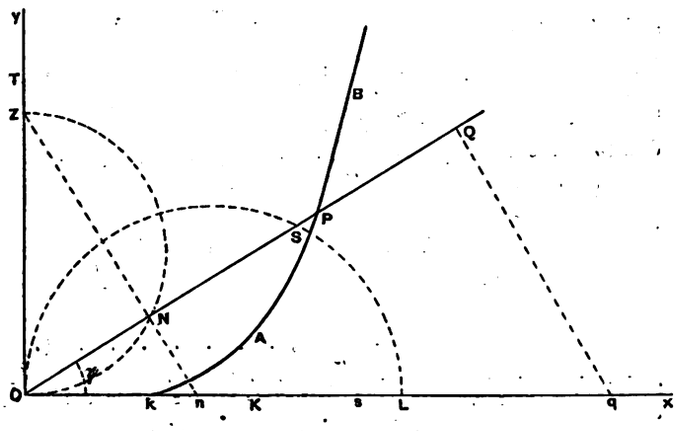

FIG. 1.

Having, by means of the determination of a few points, described the curve AB, the integral $\int X\,d\psi$ is to be measured by dividing up the curve by a series of sufficiently close points, A, P_1, P_2, . . . B; then with O as centre draw a small circular arc, Ap_1, meeting OP_1 in p_1, and a small arc, $P_1 q_1$, meeting OA in q_1; similarly take Op_2 on OP_2 equal to OP_1, and also Oq_2 on OP_1 equal to OP_2; and so on. Then half the sum of the internal steps, Ap_1, $P_1 p_2$, . . . and of the external steps $P_1 q_1$, $P_2 q_2$, . . . is a very close approximation to the required integral. The limiting points, A, B, of the curve are determined by the values ψ_1, ψ_2 of ψ given by (12), by substituting X_1 and X_2 for X.

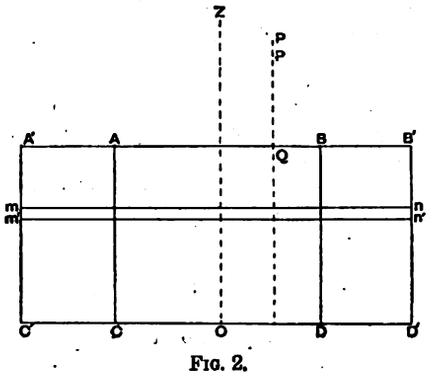

FIG. 2.

We shall now call attention to the following theorem, which is applicable to solenoids built up of coils of any shape whatever (whether circular, elliptic, rectangular, &c.), provided only that the axes of such solenoids are straight lines. The direction of the axis of the solenoid we shall call the *longitudinal direction*, while the planes of the windings are in the *transverse direction*.

Theorem: *The longitudinal component of the magnetic force at any point in space due to a solenoid of any shape whose transverse sections are all equal, similar, and similarly placed about the axis, is very simply expressible in terms of the potentials produced at the point by the two terminal faces of the solenoid.*

To see this, let Fig. 2 represent a projection of any solenoid on the plane of the paper; OZ is its axis; the hollow portion

Digitized by Google

of the solenoid is the space A C D B; the breadth of the solenoid is A A′ or B B′; and the windings (which are curves of any shape) occupy the spaces A A′ C′ C and B B′ D′ D. Let P be any point in space; let P P′ be drawn parallel to O Z, and let P P′ = h = a very small length. Take any layer, or flat coil, of the series represented by $m n$, and let $m' n'$ be the adjacent layer, the distance $m m'$ between the central cores of these layers being h. (In other words, P′ is taken distant from P by the distance between the centres of two successive layers of the solenoid.)

Now the total longitudinal force at P is the sum of the forces due to all the separate layers. Let v be the potential at P due to the layer $m n$, and v' the potential of $m n$ at P′; then the longitudinal force at P due to $m n$ is $\frac{v - v'}{h}$. Similarly, let u and u' be the potentials at P and P′ due to $m' n'$; then the force due to this layer is $\frac{u - u'}{h}$; but, obviously, from the exact similarity of positions, $u = v'$, therefore the sum of the forces due to these two layers $= \frac{v - u'}{h}$. Taking all the layers, then, from A′ B′ to C′ D′, the successive potentials all cancel in pairs in the sum, with the exception of those due to the terminal layers A′ B′ and C′ D′. If the potential of the first of these layers at P is V_1, and that of the second at P′ is V_2', we have the total longitudinal force at P equal to

$$\frac{V_1 - V_2'}{h}, \quad \ldots\ldots\ldots \quad (7)$$

and unless C′ D′ is very close to A′ B′, for V_2' we may put V_2, the potential of C′ D′ at P itself.

Hence, if the solenoid is very long, *i.e.*, if C′ D′ is very distant from P as compared with A B, the total longitudinal force of the solenoid at P is simply $\frac{V_1}{h}$.

If P is inside the hollow A C D B, the same elementary method shows that the longitudinal force is

$$\frac{4 n i \pi - (V_1 + V_2)}{h}, \quad \ldots\ldots \quad (8)$$

where n is the number of windings in each layer, since the potential of any winding at a point in its plane, and inside its area, is $2\pi i$; and, moreover, for any point inside the hollow but not very near either terminal face, there will be almost no *transverse* component of force, since the transverse components for layers above and below the point will obviously be in opposite senses; so that, except near the faces, the lines of force inside the hollow will be nearly straight lines parallel to the axis O Z.

Indeed, our theorem, above given, holds also in the general theory of attraction for any prismatic body of uniform density, whether the body is hollow or completely solid; but the theorem is not, I think, given in any treatise on attractions.

There is just this difference between the solenoid and the attracting prismatic body, that at every point the longitudinal magnetic forces due to the successive solenoidal layers are in the same sense, whether the point is between the planes of the terminal faces or beyond them; whereas, for the attracting prism, if the point lies between the planes of its terminal faces, the attractions of the parts of the body above and below the point are opposed.

For the latter body, whatever be the position of the point P, the longitudinal force is

$$\frac{V_1 - V_2}{h},$$

where V_1 is the potential produced at P by one terminal plate of very small thickness, h, and V_2 is the potential of an equally thick plate at the other end.

Inasmuch, then, as we have the means of measuring the potentials of the two end layers of any coil at any point in space, we have the value of the longitudinal force at the point.

Numerical Examples.

As an exercise for any reader who is interested in the subject, I append a few numerical examples of the application of our formulæ for rectangular circuits and coils.

1. Let there be a single flat coil whose windings are contained between the rectangles A B C D and A′ B′ C′ D′ in Fig. 3; let A′ B′ = 20cm., A′ D′ = 10cm., A B = 16cm., A D = 6cm., so that the breadth of the coil = 2cm., and the diameter of the wire = 1mm. Find the magnetic force intensity produced by a current i—

(a) at the centre, o;
(b) at q;
(c) at r,

where $p r$ and $s q$ are the principal axes of the rectangle.

Apply the formula (15), *The Electrician* for September 27th, we have $n = 20$, $b = 2$; hence

force at centre $= 22{\cdot}3 \times i$,
force at q $= 85{\cdot}6 \times i$,
force at r $= 82{\cdot}5 \times i$.

2. Let Fig. 3 represent a rectangular coil such that A′ B′ = 26cm., A′ D′ = 16, A′ F = 10, A B = 14, B C = 4, so that the windings occupy a breadth of 6cm., and let the diameter of the wire be 1mm.; find the value of the force at a point coincident with the corner C.

Here we have the potential, V_1, due to the upper layer $= 120\pi i$; and to find V_2, the potential at C due to the layer F G H K, we have $z = 10$, while the values of k corresponding to the angles ψ_{41}, ψ_{12}, ψ_{23}, ψ_{34} are 5, 2, 0, 7 respectively. Hence for the first of the corresponding four curves we have $X_1 = 9$, $X_2 = 15$, $\psi_1 = 17° 35' 27'' = 0{\cdot}307$ in circular measure; $\psi_2 = 39° 14' = 0{\cdot}6847$; so that $\psi_2 X_2 - \psi_1 X_1 = 7{\cdot}51$, and we find

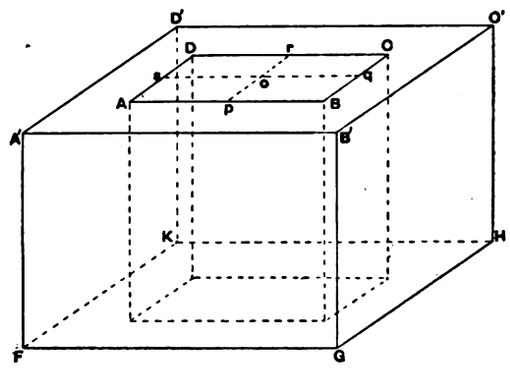

Fig. 3.

by measurement of the steps of the corresponding curve $\int X \, d\psi = 4{\cdot}575$; hence the contribution of this curve to the expression (9) is $2{\cdot}935 \times \frac{i}{h}$, or $29\,35 \times i$. In the same way the contributions of the other curves are $11{\cdot}95 \times i$, $6{\cdot}33 \times i$, and $14{\cdot}77 \times i$, so that $V_2 = 62{\cdot}4 \times i$ $\therefore V_1 - V_2 = 314{\cdot}6 \times i$, and the force at C due to the coil is $3146 \times i$ dynes per unit pole if i is taken in absolute electromagnetic units, or $314{\cdot}6 \times i$ if the current is in amperes.

Note.—In my letter to *The Electrician*, November 1st, on the magnetic force at any point in a plane circuit, for "and ω is the perpendicular from O on the first pedal of the circuit," read, "and ω is the perpendicular from O on the tangent to the first pedal at the point which corresponds to P."

THE MAGNETIC FORCE AT ANY POINT IN A PLANE DUE TO ELECTRIC CURRENTS.

BY ALEXANDER RUSSELL, M.A.

The correspondence which has appeared in your columns, due to Prof. Minchin's Papers on the above subject, has shown what an interesting problem it is when treated mathematically, but it is apt to make us lose sight of the fact that it is a very easy problem to solve practically. In a former Paper (*The Electrician*, Vol. XXXI., p. 284) I gave a method of finding the force inside a plane circuit by means of an ammeter and a small magnetic needle.

The method, briefly described, is as follows: Place the circuit with its plane vertical and at right angles to the

Digitized by Google

magnetic meridian. Send a current round it in such a direction that the magnetic force due to it opposes the earth's horizontal field inside the circuit. Increase the current until the horizontal magnetic field is neutral at the point under consideration. Suppose that when this is the case the current is A′ amperes. Then when the current is A amperes the strength of the field at the point due to the current is $H\frac{A}{A'}$ C.G.S. units, where H is the horizontal intensity of the earth's magnetic field. By this method a first-year student can easily map out the zones of equal magnetic force inside any closed electric circuit.

The problem of finding the magnetic force due to a portion of a wire is a more difficult one, but admits of several easy graphical and mechanical solutions. Ampère's method, suggested by Prof. Minchin in your last issue, namely, finding twice the area of the little triangle whose base is ds and vertex O, and dividing by r^3, is one which would give very unsatisfactory results, owing to the difficulty of finding the *small areas* with any accuracy.

The following graphical method is interesting, and is easily applied in practice with perfectly satisfactory results. Suppose that we have to find the force at O due to the current i in the portion A B of the wire C D.

With O for pole, construct a new curve $a\,p\,b$, such that

$$O\,p^2 = \frac{K^3}{O\,P}.$$

Then the force at O

$$= 2i \times \frac{\text{area } O\,a\,b}{K^3}, \quad . \quad . \quad . \quad . \quad . \quad (1)$$

i being the strength of the current in absolute measure.

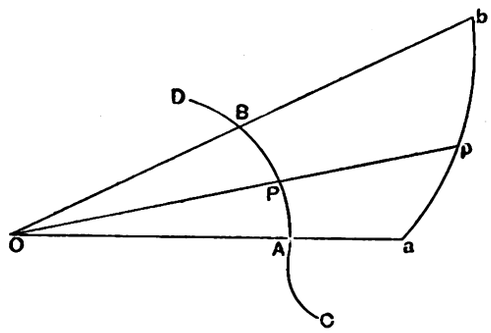

FIG. 1.

At first sight the calculations for drawing the new curve might be thought troublesome; but, by making K^3 some multiple of 10, and by having a table of reciprocals and square roots, the values of Op can be written down at once. We have only to find some six or seven positions of the point p, and draw a smooth curve through them freehand.

The proof of the formula (1) is not difficult. We know that

$$F = i\int\frac{d\theta}{r}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

where F, θ and r have their usual meanings. Now if (r', θ) be the polar co-ordinates of the inverse square curve ($r\,r'^2 = K^3$), then

$$F = \frac{i}{K^3}\int r'^2\,d\theta. \quad . \quad . \quad . \quad . \quad (3)$$

But $\int r'^2\,d\theta$ is twice the area $O\,a\,b$, hence (1) follows.

We shall apply this theorem to solve the following example, and will check the results obtained by those got by mathematical calculation, in order to obtain some idea of its accuracy.

To find the forces at P (Fig. 2) due to the portions A B and B C of the semicircular wire A B C in which a current of A amperes is flowing.

A C has been taken = 10cm., A P = 8cm., and P B is perpendicular to A C. To construct the inverse square curve for which $K^3 = 1{,}000$, we put r equal to 8, 7, . . . 2 successively and write down r' from the tables; we then, by means of compasses, find the points. It would have been easier if polar paper, similar to that recommended by *The Electrician*, had been available. As only one point has been found in $b\,c$, another was found by taking $r = 2{\cdot}4$. The curve $a\,b\,c$ was then drawn freehand, there being only two points marked between b and c, and the required areas were found by the planimeter.

The area $a\,P\,b = 128{\cdot}9$ sq. cms.

The area $b\,P\,c = 318{\cdot}1$ sq. cms.

Therefore the force at P due to the current in the portion A B is

$$F_1 = \frac{A}{10} \times 0\ 2578,$$

and the force due to the current in the portion B C is

$$F_2 = \frac{A}{10} \times 0\ 6362.$$

Now, by an approximate formula given in the Paper referred to above,

$$F_2 + F_1 = \frac{A}{10} \times 0{\cdot}8865,$$

and it can be proved by elementary mathematics that

$$F_2 - F_1 = \frac{A}{10} \times \frac{2\,O\,P}{P\,B^2}$$

$$= \frac{A}{10} \times 0{\cdot}3750.$$

Therefore $$F_1 = \frac{A}{10} \times 0{\cdot}2557,$$

and $$F_2 = \frac{A}{10} \times 0{\cdot}6307.$$

The forces F_1 and F_2 have therefore been found fairly accurately by the graphical method. The above example

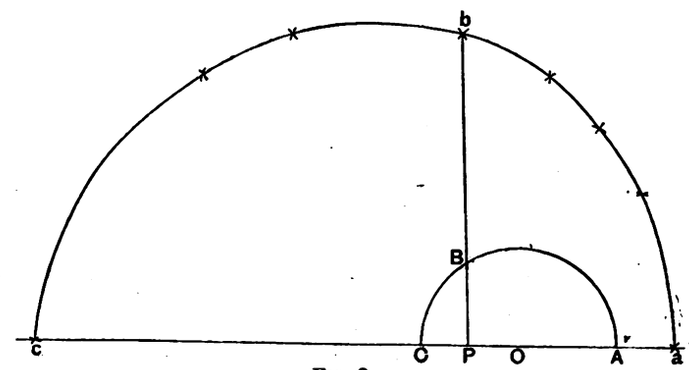

FIG. 2.

having been done very hurriedly is sufficient to prove that the method is capable of great accuracy.

An entirely mechanical method can also be used to solve the above problem. If we describe the inverse of the portion of the curve we are considering ($r\,r' = K^2$) by any simple mechanical arrangement, then

$$F = \frac{1}{K^2}\int r'\,d\theta. \quad . \quad . \quad . \quad . \quad . \quad (4)$$

From this, if we have an instrument that reads $\int r\,d\theta$, we can at once get F.

Mr. K. H. P. Powles has designed and made such an instrument. Its principle is that a little wheel always runs at right angles to r, and the distance of the wheel from the fixed origin is in a constant ratio to r. The instrument was invented to solve some integrals which occurred in certain problems we were considering; in fact, we could not solve them any other way. Applied to the particular case of a circle it calculates the value of elliptic integrals between any limits at once.* However, the former method is the one which will be found most generally useful, as no special instruments are required, it being easy to find the areas from the sectional paper used.

* The above problem is very easily solved by this integrator, for if we take $K^2 = 16$ the circle is its own inverse. Hence we have only to move the pointer over the portions B C and A B of the circle in Fig. 2, and divide the reading of the instrument by 16. The following values for F_1 and F_2 were obtained in this way:—

$$F_1 = \frac{A}{10} \times 0{\cdot}2556,$$

$$F_2 = \frac{A}{10} \times 0{\cdot}6313.$$

WATER-TUBE RESISTANCES.

Resistances, whether intended to be used "rheostatically," to reduce the current in a given circuit, or on the C^2R principle, to absorb power, have, in common with most other heavy electrical apparatus, undergone of late a very rapid

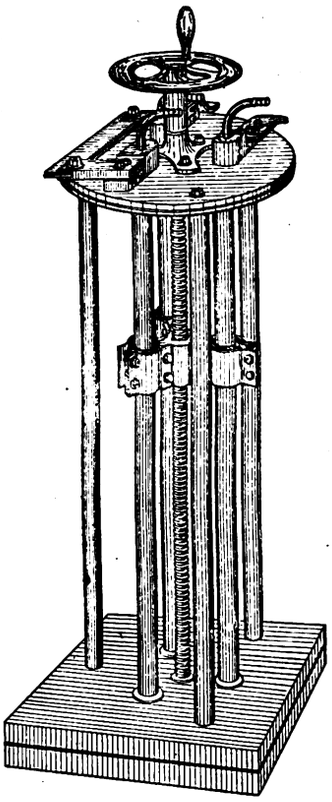

FIG. 1.—Perspective view of 5,000 ampere Water-Tube Resistance at the Board of Trade Standardising Laboratory.

process of evolution. In Fig. 1 we give a perspective view of a lineal descendant of that old and well-tried telegraph organism, the rheostat. The illustration shows a regulating resistance made by Mr. Crompton to Major Cardew's and Mr. Rennie's design, for use

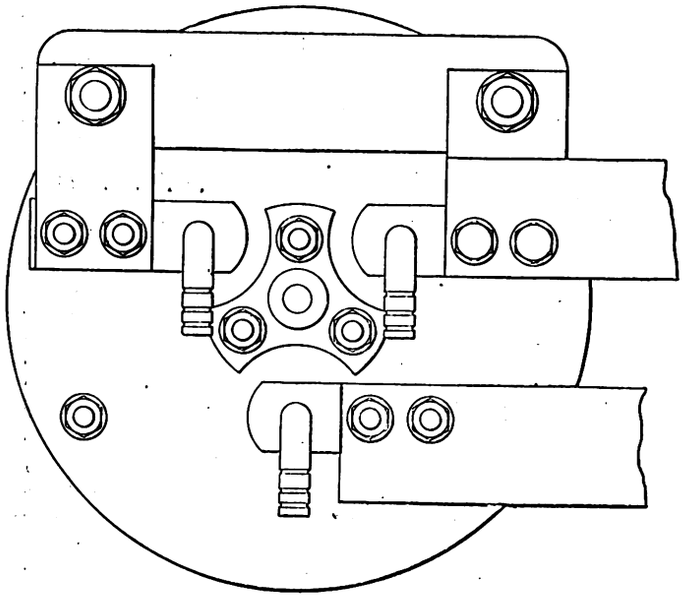

FIG. 2.—Plan of Top Connections of Board of Trade-Water Tube Resistance

in connection with the grand army of Kelvin balances quartered at the Board of Trade Standardising Laboratory. The overall dimensions of the apparatus are 3ft. 6in. high by 15in. × 15in., and its range is from 60 up to 5,000 amperes. It consists of three resistance tubes, 1 metre long, 35mm. in diameter, and 0·5mm. thick, two being of manganin (0·004 ohm) and one of copper. Through each current-carrying tube water is passed from bottom to top, carrying away the heat generated by the current, the density of which sometimes attains 30,000 amperes per square inch. These three tubes, as will be seen by the sketch, are arranged triangularly around the centre of the base. The three outer tubes are supports, and do not carry current. The current-carrying tubes are connected across by a travelling brush, adjustable by means of a screw and wheel. In Fig. 2 we give a plan of the top connections of the apparatus, as arranged at the Board of Trade Laboratory for regulating the current through the Kelvin balance circuit, the water-tube resistance being placed in series with the circuit containing the balances. The manganin tubes are placed in parallel with each other and in series with the copper tube. The whole

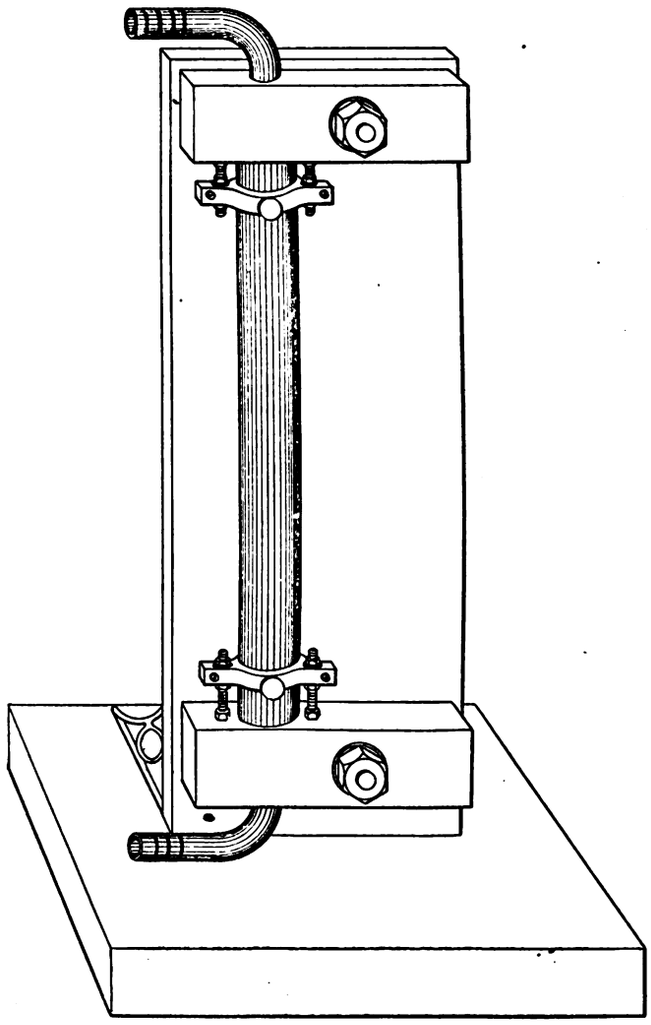

FIG. 3.—Perspective View of Standard Water Tube Resistance.

apparatus has been well thought out, and presents a very workmanlike appearance.

Mr. Crompton is also making for, anyone requiring them, a number of *standard* water tube manganin resistances. In Fig. 3 we give a perspective view of such a standard, shown us by Mr. Crompton's able assistant, Mr. W. C. Fisher; its resistance is a thousandth of an ohm, and it has therefore, with a current of 1,500 amperes, a potential difference of 1·5 volt between its terminals, the overall dimensions being base 11in. by 11in. and height 18in. In connection with potentiometer measurements of current a handy standard resistance of this type should prove invaluable. The water used in carrying off the heat generated by a current density of 15,000 to 20,000 amperes per square inch is obtained from the ordinary supply by means of a small rubber hose pipe.

WESTINGHOUSE ELECTROMAGNETIC RAILWAY AUTOMATIC SWITCH.

In our issue last week we commented on the system of electromagnetically-controlled contacts, for electric railway and tramway traction, which has recently been developed by the Westinghouse Electric Company. We are now able to give to our readers two illustrations of the details of the mechanism by which any section of the track is placed in and taken out of connection with the feeders on the passage of a car over the section. Figs. 1 and 2 show the details of this electromagnetic device, and comprise all the mechanism that is placed in each of the switch boxes along the track. One such switch box must be placed in every length of track somewhat less than the length of a car, in order that each section may come into action a moment or so before the lapse of the preceding section.

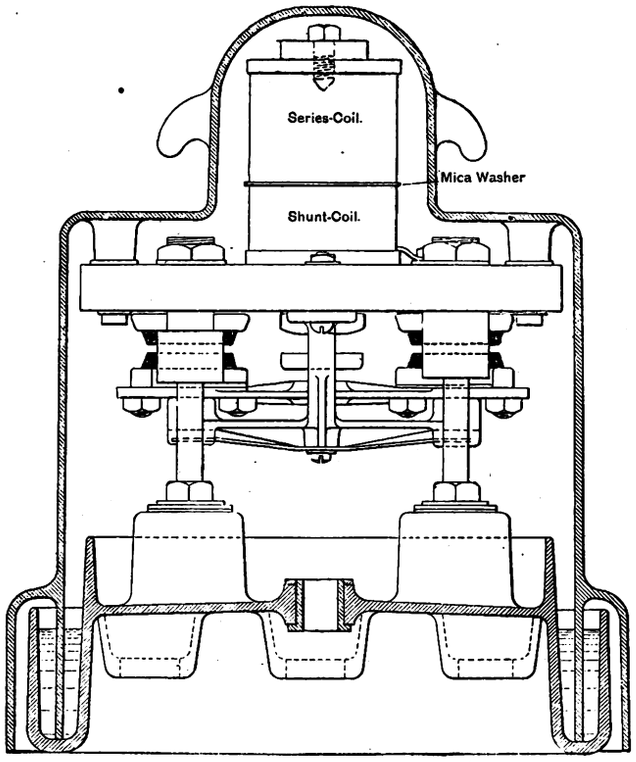

FIG. 1.

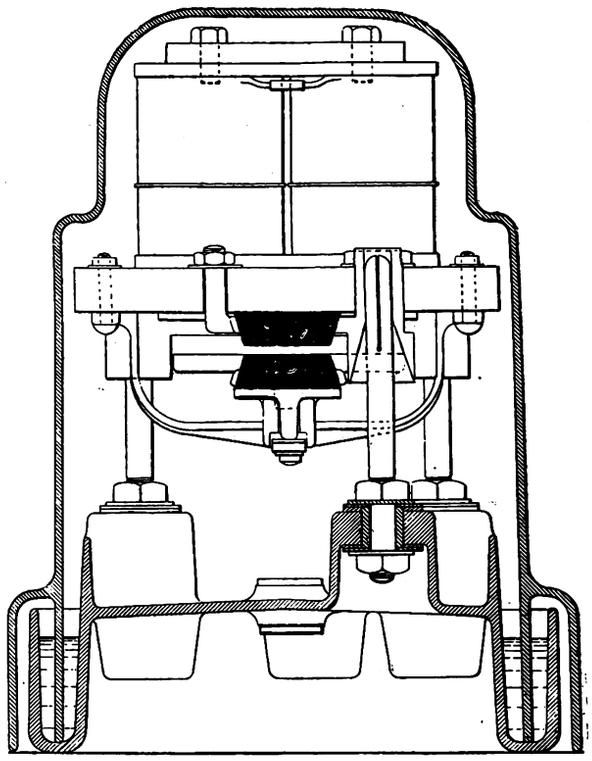

FIG. 2.

Where the cars are long, therefore, or where trailers or made-up trains will always be used, the sections may be of greater length, the number of switch boxes fewer, and the expense of these boxes less, than with small, short, single cars.

Each motor car is provided with a couple of small secondary cells; and when the car comes on to any given section of the track a current from these cells passes through a contact slider beneath the car, and through one of the two wrought-iron studs which project their well-rounded heads slightly above the ground between the two track rails; and goes to earth through a fine-wire coil wound on the electromagnet in the switch box which controls that section. Immediately, the electro-magnet is magnetised and lifts its armature, thereby bringing into contact the two pairs of carbon contact-pieces (which are shown black in the illustrations). One pair of these carbons is permanently connected to the feeder, and the other is continuously connected to the positive stud on the track, against which stud the positive collector bar of the car will by now have made contact. The negative collector bar under the car touches, at the same time, the other stud, which is connected to the return conductor. The lifting of the electro-magnet armature, and the consequent closing of the carbon contacts, therefore sends a current from the feeder through the car motors; and this current is also caused to pass through a short thick coil of few turns on the electro-magnet of the switch, thereby reinforcing the grip of the magnet upon its armature. Immediately the car passes off the particular section from which it has been deriving power, the opening of the contacts between the collector bars and the road studs will break both the power circuit and the auxiliary secondary cell circuit through the electro-magnet. At that instant, therefore, the magnet armature will fall, the carbon contacts will be separated, and the positive stud will no longer be in connection with the feeder. Thus all those road studs which are not in immediate use, and which are not by that fact lying directly beneath the cars, are not and in ordinary conditions cannot be at a dangerous electric potential, they being isolated from the live conductors of the system. The advantages of this, both from the standpoint of safety and of efficient insulation of the system, are sufficiently obvious.

The bare parts of the switch require to be maintained free from deposits of dust and moisture; and in order to ensure these conditions the whole of the mechanism is contained within a diving-bell shaped case, the lower edge of which dips into an annular oil seal. This construction is well shown in the illustrations, and it is one which very efficiently provides for the insulation of the mechanism.

THE BRIGHTON-ROTTINGDEAN ELECTRIC RAILWAY.

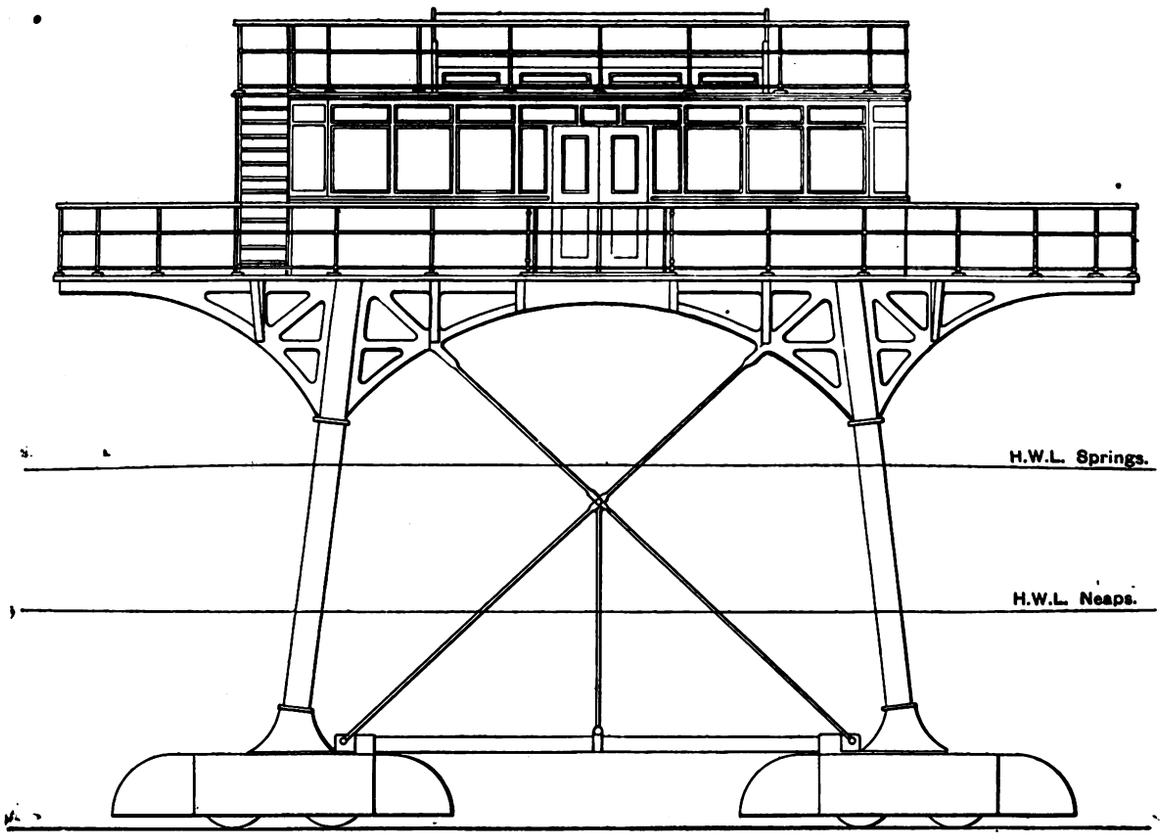
There is something almost morbid in the mania for novel sensations exhibited by seaside resorts, or rather by those who resort to the seaside. To be suspended from a steel hawser in a sort of basket and raced through the air just out of reach of the waves, a form of amusement much affected in America, is a tolerably novel experience. At Brighton, however, Mr. Magnus Volk, if he is allowed his way, proposes something scarcely less unconventional. Mr. Volk's idea is to run the steel structure shown in the illustration overleaf *through* the water from the far end of his well-known little electric tramway to Rottingdean, a total distance of exactly 3 miles; 4 furlongs 8 chains of which are within the jurisdiction of the Brighton Town Council. Hence the tears, to which reference is made in another column. The main object of the line is doubtless

Digitized by Google

to attract traffic by the novelty of running through the waves in a sort of hybrid tramcar-lifeboat conveyance. There is, however, no little justification for the tramway purely as a means of "rapid transit," as our American friends would term it, between Brighton and Rottingdean. The road is tortuous and uninteresting, and the "'bus" is slow; the proposed line is straight, and in the matter of speed and of interest should leave little to be desired. If the weather during the next six months is not altogether unpropitious, and the opposition of the Town Council is overcome without delay, it is expected that the line will be at work by June next; already all but a few hundred yards of the track has been laid.

The rails run along the foreshore at a distance of about 150 to 250 yards from the base of the cliff, slightly above low-water mark; at high tide they are covered by 14ft. of water. Instead of two rails connected by tie-rods, there are two *pairs* of 54lb. rails, a distance of 18ft. intervening between the two outers. Each pair of rails (2ft. 8½in. gauge) is laid separately, on concrete blocks mortised to the chalk below. In 1893, when the Act was obtained, the chalk was covered in some places by a layer of sand 3ft. thick. During the storms of last winter the sand was all swept away, to be subsequently slowly silted up again. The steepest gradient is 0·3 per cent.; the sharpest curve has a radius of half-a-mile.

The car, which was designed by Mr. St. George Moore, joint engineer to the Company with Mr. Volk, is being built by the Gloucester Waggon Company. It is supported by four splayed-out legs, each leg consisting of a 12in. steel tube, running on a four-wheel bogey. The wheel base is 28ft. Each of the two leading bogeys will be driven off vertical shafting inside the tube by a 30 H.P. vertical motor, to which current will be conveyed on the overhead trolley system at a pressure of 500 volts. The deck of the car will be 24ft. above the rails, and will measure 50ft. by 22ft.; it will carry a saloon 25ft. by 12ft. The structure by itself will weigh 40 tons, and, with motors, gearing, and 150 passengers, the total weight will be 60 tons. The speed expected to be realised is six miles an hour.



Elevation of Latest Pattern Car.

The Brighton-Rottingdean electric line presents several exceedingly interesting electrical and mechanical problems, and engineers will wish Mr. Volk every success in his new venture.

THE BRIGHTON TOWN COUNCIL AND THE ROTTINGDEAN ELECTRIC SEASHORE RAILWAY.

As the dispute between the Brighton Corporation and Mr. Magnus Volk is a matter of more than local and personal interest, involving as it does the important question of the relative merits of electric and gas motors for traction purposes, we give in full the reports on the subject presented at last week's meeting of the Town Council by the Borough Surveyor and the Borough Electrical Engineer, together with the comments of the Brighton and Rottingdean Seashore Electric Tramroad Company and the Report of their Engineer; we also append a brief abstract of the proceedings at the meeting of the Town Council on Thursday, October 31st:—

BOROUGH SURVEYOR'S REPORT.

In obedience to your command to place before you all the facts relating to the construction of this tramroad, I beg to say that when the promoters first submitted for your consideration the Bill by which they proposed to seek for Parliamentary powers to construct their tramroad, and the plans which are always deposited with such Bills, your Committee were distinctly informed:—

1. That there would only be two lines of rails, about 26ft. apart.
2. That these rails would only project 4in. above the surface of the chalk, or sand, forming the foreshore or beach.
3. That the line would not interfere in the least degree with the construction of any new groynes, as it could easily be carried over any such groyne, or round the south end of it at any point.
4. That the car would be of light construction.
5. That the car would be easily driven by electricity from accumulators carried on the car.

If these arrangements had been adhered to there would have been—

(*a*) Practically no risk to bathers or boats.

(*b*) The groyne at Black Rock would have been constructed as originally designed and approved by the Town Council solely as the best method of protecting the eastern foreshore.

(*c*) There would have been no obstruction to the free use of the sea, nor anything visible above the water.

Digitized by Google

The original proposals have been departed from in the following particulars:—

1. There are four lines of rails about 18ft. wide between the outside rails.

2. Without having first obtained the sanction of the Town Council, the minimum projection of the rails above the chalk has been raised from 4in. to 18in., and rises from this to 2ft. 3in. at Paston-place groyne; but the consent of the Council has been obtained, on the recommendation of your Committee, to raise the line to 3ft. above the chalk at Black Rock groyne.

3. By the special request of the Company, and on the recommendation of your Committee, the Town Council has agreed that the concrete groyne at Black Rock shall be reduced from 7ft. 6in. to 3ft. solely for the accommodation of the Company, to enable them to carry their line over the groyne, instead of constructing it in low water beyond the south end of the groyne.

4. The car and the gantry on which it is carried, as it is now being constructed, is designed to carry 150 persons, and is estimated to weigh when finished upwards of 40 tons, exclusive of the weight of the motors and driving gear, and of the weight of the passengers. The total weight of the car and passengers will therefore probably be little short of 60 tons.

5. It is the intention of the Company to abandon the use of accumulators, and to drive the car by overhead wires carried on poles, a method know as the "trolley system," if the Council will give their assent to the proposal.

The effects of these deviations from the original proposals are—

(*a*) The lateral obstruction caused by the rails is doubled.

(*b*) The additional height of the rails is likely to be a source of danger to bathers and to boats, when hidden from view by shallow water only.

(*c*) The reduction of the height of the groyne at Black Rock as originally designed, although perhaps unimportant at the present time, may in future years seriously detract from its usefulness.

(*d*) The increased weight of the car and its gantry will make it of such unwieldy and ponderous proportions that it will have a very different appearance to that of the little elegant toy car at first proposed to be used by the Company, and of which a model was submitted to you. You will gather some idea of the proposed car if you will realise that it will be equal to the weight of five or six steam road rollers or of an ordinary railway steam locomotive.

(*e*) The proposed poles and overhead cables are likely to be an obstruction to the sailing craft at high water, in rough weather and at night, owing to the poles and wires being invisible.

With regard to the application of the Company for your permission to erect within the borough thirteen cast-iron poles 21ft. above the high water line, with arms 4ft. long, to carry two lines of cable, or overhead wires, for the purpose of driving the car by what is known as the "trolley system," you instructed me to confer with the Corporation Electrical Engineer, and to call in other expert assistance if we required it, to consider whether the overhead wire system is the only one that can be adopted by the Company. I beg to say that we have conferred together as directed, and your Electrical Engineer will send in his special report upon the subject of electric traction, and its method of application; also as to the practicability of adopting a motive power other than electricity, in order to avoid the use of overhead wires; therefore I need not refer to that part of the subject.

It is, however, within my province to report to you that, in considering the subject from a broad or general engineering point of view, it was necessary that we should be supplied with further information respecting the scheme than that which had already been furnished. I therefore put the following questions in writing to the Engineer of the Company, but I have not yet received any written replies thereto:—

1. What is the weight of the proposed car?

2. At what speed will it be driven?

3. What is the maximum horse-power required to drive it at any part of the line at the time of high tide?

4. On what data is this power estimated?

5. Send a detailed drawing of the car, with the motors and trolley attached.

The Company's Engineer and their Electrical Engineer, however, afterwards called together to see your Electrical Engineer and myself. They courteously offered to give us all the information they could, and we elicited from them at the interview that it was impossible for them to give us definite information in reply to the questions I had put to them, because, as the project is entirely a new departure in engineering, there is no known data or formula on which they could base their calculations. They assured us they had done their best to arrive at correct conclusions from their own experience, and such other information they possessed as could be applied; but, at the same time, frankly confessed that their conclusions are, to a great extent, problematical, and that it is by experience only, after actual experiments made on the line, that more reliable information can be obtained or given.

I quite believe this to be the true state of the case, and in view of the facts that the Company have found it necessary to depart entirely from the first arrangements—that they have no reliable knowledge that the present proposals are workable—that they need knowledge which can be gained only by actual experiments—that your Electrical Engineer is of opinion that a motive power other than electricity may, in practice, be found better and cheaper than electricity—and having been informed by the Company's Engineers that neither the engines, dynamos, poles or wires have yet been ordered, I recommend your Committee to endeavour to make an arrangement with the Company for them to complete so much of their line as is outside the borough, and to make their experiments thereon. This line is 2 miles 2 furlongs 2 chains in length, and, therefore, affords sufficient scope for the purpose. The line within the borough is only 4 furlongs 8 chains in length, and could be easily finished when the Company had ascertained all the necessary particulars for working it successfully. These experiments and their results would afford your Committee and the public an opportunity of forming a correct opinion as to whether the project is likely to be beneficial or prejudicial to the interests of Brighton.

COMPANY'S NOTES *RE* SURVEYOR'S REPORT.

2. This was an impossible condition imposed in the Corporation Protection Clauses, owing to the undulating surface of the chalk and the shifting sand, and was not in our original Bill at all.

(*a*) The line as constructed does not cause any additional risk either to bathers or boats.

(*b*) The following letters will show the site of the line was moved to allow the new groyne as originally designed to be constructed, and the line as now laid is 100ft. from the timber groyne, and that it was an amended proposal, of which we had no notification for twelve months afterwards, that caused all the difficulty.

(*c*) The poles would be a distinct advantage as indicating the position of the line.

1. The total width of the line is now only about 16ft., instead of 24ft. as originally intended.

2. The words "or sand" which are in our Act have been omitted after the word "chalk." The line was laid to conform to these conditions as far as possible; but the sand was withdrawn by gales when the Surveyor measured the work. Since then, on two occasions, the rails have been covered with sand. A photo, showing the sand level with the rails, will, if possible, be in the Council Chamber.

(*a*) The rails being at one level, the lateral obstruction is the same whether two, four, six, or any other number be laid.

(*e*) With regard to this matter, the wires would be erected high enough to clear all small sailing craft. The submerged ends of the groynes, which project considerably further to sea than the line of rails, would cause all vessels to keep a course far outside them; whilst in stormy weather, when the whole shore is covered with breakers, a vessel getting within their influence would be wrecked any way, and the poles and wire would offer no obstruction to her coming ashore, and as at such times no current would be in the wire, no inconvenience could arise from this cause.

BOROUGH ELECTRICAL ENGINEER'S REPORT.

As requested by your Committee, the Borough Surveyor and myself have carefully considered the new proposal of the Rottingdean Tramway Company for driving their car, and we agreed that it would be well for us to put our views in the form of two separate reports.

I therefore beg to state that, judging as best I can from the unfortunately very scanty information obtainable from the Engineers of the Company as to the horse-power required by a car running under such novel and difficult conditions, I am of opinion that, as steam power is considered by the Corporation to be inadvisable, the only two remaining systems known to me, by which there is any probability that such a line could be worked so as to be a mechanical and, possibly, a commercial success, are:—

First, the ordinary trolley overhead wire electric traction system, as used in America, Bristol, and other places.

This method, although it involves the use of overhead wires, has the advantage of great flexibility, in that an almost unlimited amount of power can be conveyed to the motors on the car. I consider this, under the circumstances, a great advantage, as it appears that only the most hazy ideas are obtainable as to the horse-power required to drive the tramcar through the water at anything like a reasonable speed. Other advantages are that the trolley system has been well tried and worked out, and is very cheap to instal.

Second, the compressed gas-motor system, as about to be used at Blackpool and in use on the Continent, in which the necessary gas is carried in tubes under the car in a compressed state.

This method has the great advantage over the first of being practically self-contained. Theoretically, it certainly ought to be cheaper in initial cost and maintenance than the other system, and, considering the particular line of route, I am not aware of any feature which would render it unsuitable for the tramway in question.

In my opinion it is quite possible to drive the car by the ordinary electric accumulators, but I consider this system to be unsuitable by reason of its much greater expense, both initial and maintenance, than either of the other two systems, and I do not consider that any combination of the electric accumulator and trolley systems could be satisfactorily worked in practice, as there are serious technical difficulties involved in the suggestion of working the car by accumulators while in the Brighton Borough, and the trolley system when beyond it.

Owing to the impossibility of ascertaining the horse-power required to drive the car with its full complement of passengers, as neither the weight to be moved nor the amount of resistance due to wind and water or other friction appear to have been ascertained, and as no drawings have been submitted to me showing the proposed method of driving the wheels from the motors, I am quite unable to express a more definite opinion as to the practicability of the project beyond stating that I think it would be quite as possible to drive the car by compressed gas as by the overhead wire trolley system, especially as I understand it is only intended to run one or, at the most, two cars.

The Committee report that they have also received communications from Sir Albert Sassoon and Colonel Wilson, stating that they have no objection to the carrying out of the proposal, and from Mr. Mellor, on behalf of the Kemp Town Enclosure Committee, objecting to the erection of the poles.

The Committee submit the application of the Company for the decision of the Council,

REPORT OF THE ENGINEER TO THE BRIGHTON AND ROTTINGDEAN SEASHORE ELECTRIC TRAMROAD COMPANY.

GENTLEMEN: In accordance with your instructions, I herewith beg to report on the subject matter of the report of the Works Committee to the Town Council as follows:—

With reference to the gauge of the rails being altered from 24ft. to 18ft., and the number of lines of rails being increased from two to four, I beg to point out that these alterations were sanctioned by the Corporation prior to the commencement of the work.

The alteration in the level of the rails was rendered necessary by the height of the sand while the works were being carried out. The Borough Engineer stated to the Works Committee on their visit to our works that, judged from an engineer's point of view, he did not consider the rails had been laid one inch higher than was necessary to enable the line to be worked.

I beg to enclose with this report two drawings to the same scale, A being the "model car" referred to by the Borough Engineer, and B the car as now being constructed.

I beg further to report that on the 15th inst. I received a letter from Mr. May, asking for certain information as regards the car, and in order to save time I went to Brighton on the 15th inst., saw Mr. May and Mr. Wright early on the 16th inst., and gave them the following replies to their questions:—

Q.—What is the weight of the proposed car? *A.*—The weight of the structure would be about 40 tons, and the weight of the electric machinery and people would bring it up to from 55 to 60 tons.

Q.—At what speed would it be driven? *A.*—We expected that the power we proposed putting on board would enable us to travel at an average speed of six miles per hour.

Q.—What is the maximum horse-power required to drive it at any part of the line at the time of high tide? *A.*—That we proposed putting two 30 H.P. motors on the car, which in our opinion would suffice.

Q.—On what data is this power estimated? *A.*—On the resistance (1) due to traction on the level, (2) due to the greatest incline, (3) due to the curve, (4) due to the wind, (5) due to the water, (6) due to the skin friction.

Copies of the drawings sanctioned by the Board of Trade were handed to them the same day. Pending the settlement of the question now before the Corporation, detail drawings of the electrical arrangement have not as yet been made, so I was unable to supply them with these, but at the same time explained that the trolley pole would be as sanctioned by the Board of Trade for the Bristol Tramways.

I did not understand from Mr. May that he wished me to repeat this information in writing.

I cannot understand what experiments Mr. May desires should be made outside the Borough boundary, and what object would be gained by the stoppage of the works within the same.

In reference to this I must point out to you that owing to the short time the work within the borough boundary is uncovered by the tide, we have only been able to complete 50 yards of the line between September 5th and October 21st, so that any further stoppage of this portion of the works would render it impossible to complete the same within the time allowed by the Act of Parliament which expires in July next

The only point which now remains to be determined is what speed will the car travel at with a certain amount of power.

The great flexibility of the overhead wire system (as stated by Mr. Wright, the Electrical Engineer to the Corporation) in that an almost unlimited amount of power can be conveyed to the cars, coupled with the following facts—

(*a*) The system has been well tried and worked,

(*b*) The large range of power that can be obtained from electric motors,

(*c*) That the motors can easily be changed,

are the reasons which had led the advisers to the Company to adopt this system, thereby ensuring that there will be sufficient power available to drive the car at a satisfactory speed.

With reference to Mr. Wright's (the Electrical Engineer to the Corporation) suggestion as to the adoption of gas engines, this method of driving was carefully considered prior to applying to the Corporation on May 14th for permission to temporarily use steam, and was abandoned for the following amongst other reasons:—

1st. No gas engines for traction purposes have been made approaching the power required.

2nd. The vibration in the compressed-gas motor cars to which Mr. Wright refers, although the motors are close to the ground, is considerable; therefore it is evident that if motors ten times the power of these were placed on our high car, the vibration would be so excessive that passengers would not travel on it.

3rd. The objectionable smell and noise.

4th. Serious mechanical difficulties in reversing and starting in the case of large powers, and where the inertia of our large car would have to be overcome.

5th. The manufacturers, although willing to make an engine of sufficient power, would not, on account of the above-mentioned difficulties, undertake any liability as to the effective working of the arrangement.—Yours obediently, (Signed) R. ST. GEO. MOORE,

Engineer to the Company.

MEETING OF THE BRIGHTON TOWN COUNCIL, OCTOBER 31ST.

Alderman BRIGDEN moved that the Report of the Works Committee on the application of the Brighton and Rottingdean Seashore Electric Tramway for leave to erect steel poles on the foreshore from Paston-place eastward be entered on the minutes. The Committee, he pointed out, made no recommendation, but left the matter entirely in the hands of the Council. He wished the Council, however, to understand that the Committee to a man had no hostility to the electric railway. It was a unique and novel venture, and they were all desirous of seeing it carried out satisfactorily.

The motion was put and carried.

Councillor BOOTH moved the following resolution: "That the application of the Brighton and Rottingdean Seashore Electric Tramroad Company, dated September 23rd, for permission to erect 13 tubular steel poles 80 yards apart on the foreshore between Paston-place jetty and the borough boundary at Black Rock, for the purpose of carrying the electric trolley line, be, and is hereby granted, provided that the Company pay a rental of £1 per annum, and enter into a covenant to remove the poles on receiving three months' notices." He contended that the railway would be of the utmost benefit to the town, and would bring people to Brighton from the ends of the earth. Only a sixth of the whole line was within the jurisdiction of the Council, and he maintained that as the Board of Trade had more knowledge and greater responsibility in the matter than the Council, they would have been the first to raise objections if there had been any of a substantial character. As to the changes that had been made in the plans, he contended that they were essential in any invention.

Alderman ABBEY urged that the present scheme was a complete departure on the part of the Railway Company from the old scheme that was partially assented to by the Town Council. It embraced all the objectionable parts of the old scheme, and now was added these poles and the overhead wires, the result of which would be that the inhabitants of Brighton would be deprived of a quarter of their foreshore. The foreshore of Brighton was nearly 4,000 yards in length, and it was proposed to destroy the use of it for about 1,000 yards. In granting this the Council should have some guarantee, some security in the way of a deposit, that in the event of a railway not being carried out the *débris* would not be left, probably for years, as a monument of their foolhardiness. His amendment was that the application be granted conditionally on £1,000 being deposited as a security for the whole of the *débris* being cleared away if the railway did not answer, and that the whole matter be referred to the Works Committee to carry out. After some little delay Alderman ABBEY put his amendment in this form: "That the motion be amended by adding the following words: Provided that the sum of £1,000 is deposited by the Company with the Corporation by way of security for the removal of the tramway in the event of its being abandoned at any time hereafter, and that the details as to the application of such security be embodied in an agreement to be approved by the Works Committee."

Councillor DANIEL said Councillor Booth entirely ignored the fact that the Surveyor had, at the request of the Committee, reported on this application, and had practically told them point blank that they would be doing a very foolish thing if they granted this application.

Councillor GEORGE pointed out that the Council had already granted the Company the power to raise their line 3ft. above the proposed groyne. That might be a very great obstacle to the boating interest, but it had been done.

Councillor SUTTON said he supported the application almost entirely on the two reports furnished by the Council's own officials. The reduction in the height of the groyne was a matter already settled by the Council; and, moreover, he thought it unfair to press for the Company being bound down to full details when the Surveyor admitted in his report that it was at present impossible to give them. But in the report of their own Electrical Engineer the Council would find all the justification necessary for granting the application. Mr. Wright said the trolley system was the best means to work the line to ensure financial success.

Councillor BLAKER said if the 13 poles had been in the original proposal, it would never have been listened to, and he considered the present scheme a violation of the rights of the people.

Councillor DUTTON BRIANT said he found in an inspired article on the railway that the sand had shifted very much since the commencement of the undertaking, from which one might fear alteration in the future that would seriously affect the railway. Then the lines, he understood, were placed on concrete blocks "mortised into the rock." But the only rock was chalk, and with the vibration of a 60-ton car going over them, was there any likelihood of the concrete blocks being able to hold on? He was anxious to see the railway a success, but these objections, in his mind, would have to be removed before he could support the proposal at all.

Alderman MOON said that Mr. Wright, instead of recommending the trolley system, really recommended the gas motor system. He reminded the Council that in the first instance the promoters said the car would be run by means of accumulators. This, it turned out, was not impossible, but would probably prevent the railway being a commercial success. This was not the fault of the Council, nor of the Works Committee. They naturally supposed that when gentlemen commenced an undertaking they counted the cost, and did not begin until they knew they could finish. It seemed to have dawned on the promoters in some way that the car, instead of a light thing, would have to be 40 tons in weight, or with passengers and motors 60 tons. That was not the fault of the Council or the Works Committee. Then the Company raised their rails from 4in. to 18in. without any notice to the Corporation, and now they asked for leave to erect thirteen steel pillars of a considerable height with brackets to carry a cable about ½in. diameter, probably with suspending cables. It was not only a question of the danger to boating and bathing, but of how far this was going to interfere with the beautiful view.

Alderman REEVES suggested for the consideration of the Council whether, at a private meeting of the Council in about a fortnight's time, with the Electrical Engineer, the Surveyor, and the Engineer to the Company present, they would not be able to arrive at a better understanding on the matter, and a more just conclusion than at present. After some hesitation, Councillor BOOTH accepted this proposition, and

Digitized by Google

amendment and resolution were withdrawn by leave of the Council. On the motion of Alderman REEVES, it was then formally decided that the debate be adjourned to a convenient time, about a fortnight after the election of the new Council, that the Company be invited to send their Engineer, and that the Borough Surveyor and Electrical Engineer attend.

THE ELECTRIC LIGHTING OF EDINBURGH.*

BY HENRY R. J. BURSTALL.

(Concluded from page 18.)

The arrangement of the switchboard and conductors is as follows: The feeders enter the building at a cellar under the pavement on the west side, and are brought along the wall under the platform in the form of heavy copper rods, which are carried on insulators, and pass up through the floor to their respective terminals at the back of the switchboard, and are attached to the terminals at the top of the board by cones and nuts. They are connected, through a duplex fuse and an ampere-meter, to heavy vertical copper bars on the front of the slates, each bar having three holes in it, through which plugs can be inserted. The leads from the dynamos are carried in the form of insulated cable to their respective terminals at the back of the board, near the bottom; and through fuses, automatic switches and ampere-meters are connected to vertical copper bars fixed to the front of the slates, similar and parallel to the feeder bars. The automatic switches are so constructed that the switch, after being closed by hand, is held in place as long as the current flowing through it exceeds from 15 to 20 amperes; should it fall below this, a trigger is released and the switch is automatically opened, thus breaking the circuit and preventing damage if a machine should fail from any cause. Three heavy copper "omnibus" bars are fixed horizontally at the back of the three outer slates on each side, and are capable of being connected to any of the feeder and dynamo bars of that side by means of heavy copper plugs, which are inserted through holes in the vertical bars and slates, and screw into the omnibus bars at the back, the contact being made on the front bars by a faced collar. The feeders under ordinary circumstances are all connected to the top omnibus bar, and are all in parallel. In order to connect any dynamo to the feeders, plugs are screwed into the top holes of the vertical bars corresponding with that dynamo, the brushes of the machine are put down upon the commutator, and the stop valve of the engine is fully opened so that the engine is running on its governor; the switchboard attendant regulates the electromotive force of the machine until it is equal to that shown on the voltmeter between the top bars, and then closes the automatic switch, putting load on the dynamo by taking resistance out of its field circuit. During the whole time the machine is on circuit it is regulated by the switchboard attendant, the engine running on its governor with the stop valve full open; the engine driver has to attend only to the running of the engines and dynamos. For the sake of economy, however, the engines are run somewhat slower at low loads than at full load; after about three-quarters of the full load has been reached, the setting of the governor is altered, and the engine run at full speed. In order to take the machine off circuit, resistance is put into the field circuit until the current falls so low that the automatic switch opens; the driver then lifts the brushes out of contact, and shuts down the engine.

Balancing Machines.—The foregoing description applies only to the high-volt machines; the connections for the balancing machines are somewhat different (Fig. 3). The leads for each of these dynamos are connected—through fuses, ampere-meters, and automatic switches, as for the high-volt machines—to two contacts of a double-pole switch on the centre panel; and can be connected alternatively with two of three contacts, one of which is connected to the middle wire and the other two to dynamo bars on the positive and negative sides of the switchboard respectively. Thus each balancing machine can be put between the middle wire and either the positive or the negative side of the switchboard. These machines are run in exactly the same manner as the high-volt machines, and the whole of their regulation is done from the switch platform.

In the circuit of each dynamo is a registering ampere-hour meter, from which are taken readings whenever the machine is started and stopped; and the station records of the units generated are made up from these readings. Voltmeters are provided, which can be connected to the terminals of each dynamo by means of multipolar switches; other voltmeters are also connected, so as to show the electromotive force between any of the omnibus bars on the positive and negative sides, and also between the omnibus bars and the middle wire. A pair of voltmeters are fixed on the upper part of the centre slate, and are connected through multipolar switches, so as to show the pressure between the middle wire and the positive and negative wires respectively at any feeding point on the system; and for this purpose light wires are brought back from the feeding points. The switchboard attendant is thus able to know directly the electromotive force on the distributing mains; and regulates the electromotive force at the switchboard so as to keep this constant.

The two lower horizontal omnibus bars can be connected by plugs to any feeder or any dynamo; by this means it is possible to run any feeder or feeders at a higher or lower electromotive force than the others, should occasion arise. The same two bars are also used for testing, and for the introduction of standard instruments into the circuit of any feeder, dynamo, or battery, for the purpose of checking or calibrating the switchboard instruments without breaking any permanent connections or running the circuit on temporary connections. The instrument or standard resistance, &c., is connected between two of the omnibus bars, and the dynamo or feeder, &c., is plugged on one of the lower omnibus bars; the current passes through the resistance, &c., to the top bar, which is on the outside circuit. In the actual running of the station considerable use is made of these spare omnibus bars.

Battery.—In ordinary circumstances the two outer ends of the batteries are plugged on to the top omnibus bar on the positive and negative sides of the switchboard; but can be disconnected either by removing the plugs or by the emergency switches. One of the cells near the inner end of each battery is connected with the middle wire through the regulating switch. Save under exceptional circumstances, however, the electromotive force of the whole battery in series would be much too high for the circuit; and therefore by means of a regulating switch any number up to twenty-six of the inner cells of each battery can be put in parallel with the inner cells of the other battery, thus keeping the electromotive force of the battery the same as that required at the omnibus bars to which the feeders are connected. When the dynamos are running, the battery-regulating switch can be set so that no current is passing into or out of the battery: putting more cells in parallel will lower the electromotive force of the battery, which will then be charged by the dynamos; while putting fewer in parallel will raise the electromotive force of the battery, and cause it to discharge and thus to help the dynamos. Under normal circumstances the battery is charged while the load is light, more or less current being put into the battery as the load on the external circuit varies so as to keep the engines running at that time as fully loaded as possible. During heavy load the battery is kept as far as possible with no current going either into or out of it; only after the dynamos are stopped is it discharged at all heavily, or when the load suddenly rises, and then only for short intervals. This method of regulating the battery by putting the centre cells in parallel, which is due to Mr. B. M. Jenkin, necessitates connecting up to the regulating switches more cells than the usual arrangement of regulating by cutting out cells on the outer ends of the batteries; but it renders the manipulation of the battery much more simple, and does away to a great extent with the somewhat troublesome charging of the back cells, that is to say, the cells at the outer end of the batteries, which also in the usual arrangement may be used for only a few hours or even only a few minutes in the day, while they have always to be charged and kept ready for work.

Battery Connections.—The connections to the battery may appear somewhat complicated, but in actual work the regulation of the battery is effected by moving only one wheel like a steering wheel, fixed on the middle slate of the switchboard. The switches themselves are placed in the battery room above, and are worked by wire ropes from the wheel below. A special circuit and switch is provided, by which the cells that are in parallel can be charged independently of the rest of the battery; but in actual work this is not regularly used. In this arrangement of battery regulation the whole of the cells in the battery are always used, but the centre cells are not charged or discharged to such an extent as those which constantly remain in series. By properly choosing the time of charging, the regulating cells can receive rather more charge than they discharge; and in order to enable the charging to go on at light load, when there is only a small drop on the feeders, the "hospital" or "milking" cells are connected up, as shown in the diagram, four on each side of the system, through two small switchboards on the switch platform. By suitably arranging the switches these cells can either be put in series with the main battery, or be put between the dynamo charging the battery and the feeders; in the latter case part of the current goes to the battery and part on to the circuit. The electromotive force of the dynamo charging the battery can thus be made higher than that required at the station end of the feeders; and the battery can be charged with more of the regulating cells in series than would be possible if it was in parallel with the circuit. This arrangement has the additional advantage that full use can be made of the hospital cells, which are usually standing idle unless any cell in the battery requires assisting. When used for this last purpose, the hospital cells are cut entirely off the circuit, and are put, two in series, in parallel with any cell which shows signs of weakness

* Paper read before the Institution of Mechanical Engineers.

Digitized by Google

during the discharge of the main battery; connections are made from the hospital-cell switchboards in the engine room to terminals in the battery room, and adjustable resistances and ampere-meters are put into each of these circuits, so that the current passing from the hospital cells to the weak cell can be regulated, and is always under control of the switchboard attendant.

Battery Room.—The battery room is directly over the west end of the low-tension engine room (Fig. 2), and is reached by a spiral staircase directly from the switch platform. It has a fire-proof floor covered with acid-resisting asphalt, and is well lighted and ventilated, having windows on both sides of the room, as well as a ventilator in the ceiling. The battery consists of 132 cells of the new Crompton-Howell 31-plate type. It is divided up into two half-batteries, positive and negative; and is arranged in two tiers on four rows of stands, which are of cast-iron, with wooden longitudinal bearers carrying the cells; the eight hospital cells are arranged on separate stands. All the cells are similar, and have each a nominal capacity of 1,000 ampere-hours, the normal rate of discharge being 200 amperes. They are contained in lead boxes, and stand on glass oil insulators upon the longitudinal wooden bearers. The 26 cells in each half nearest the middle wire are connected up by solid copper rods with the regulating switchboard, which stands directly over the main switchboard below. Provision is made for a second battery of similar size, should it be necessary in the future. In the battery circuit there is a registering ampere-hour meter between the outer end of the battery and the switchboard, so connected that its pointer goes backwards on the dial during the charging of the battery, and forwards during the discharge. The mechanism is such that the pointer is 10 per cent. slow on the charge; thus, if the pointer is always brought back to zero by charging the battery, 10 per cent. more current will be put into the battery than is taken out. This percentage can be altered from time to time, as may be judged necessary. The regulating switchboard is connected up to the battery bars on the main switchboard, which are similar to the dynamo bars, and is also connected up to the middle wire. These connections, as well as the special connections for charging the parallel cells and for the hospital cells, are carried in the form of bare copper rods by insulators on the engine-room wall to their respective terminals. The battery has ample capacity to meet the whole of the load of the station from daylight till the evening; thus during the summer time it can do the lighting during more than half the whole 24 hours.

High-tension Engine Room.—The high-tension portion of the station consists at present of only two engines and alternators with their switchboard (Figs. 2 and 3), and the rectifiers for arc lighting with their regulating arrangements and switchboard; but in the immediate future this plant will be considerably extended. Each of the alternators is driven direct by a Willans three-crank engine of 150 I.H.P. on the same bedplate. The alternators are of the "Portsmouth" type, with some modifications necessary owing to their increased speed of 450 revolutions per minute. Their armatures are stationary, and are of great strength; the core, consisting of sheet-iron segments, is solidly bolted into the framing of the machine, with the coils threaded through holes in the sheet iron, well insulated, and completely enclosed in brass boxes. The field-magnets revolve, and consist of two heavy cast-steel discs, having on their circumference claws projecting sideways alternately over the field winding, which is between the discs, and is well protected from injury. The exciting current is taken from the low-tension switchboard at 230 volts, and is only a few amperes. The alternators work at an electromotive force of between 2,000 and 2,200 volts, with a frequency of 52½ complete alternations per second. The main leads from the alternators, which are concentric, as well as the leads for the exciting current, are taken to the switchboard in chases similar to those in the low-tension engine room. The arrangement of steam, exhaust, and drain pipes is similar to that already described for the low-tension engine room.

Switchboard.—The switchboard stands on the switch gallery (Figs. 2 and 3), and is built up of slabs of slate, forming shelves projecting from the west wall of the engine room, and divided up into compartments for each alternator and circuit by slate partitions. The outer pole of each circuit and each alternator is connected to an earth plate at the station, the whole of the rest of the system being insulated from earth; owing to this arrangement all the switching can be done on the inner pole, which renders the switchboard and its manipulation very simple. The inner pole of each alternator and each circuit is connected to two similar switches through ampere-meters and fuses, and can by these switches be connected to either or both of two omnibus bars at the top of the switchboard. In this way any alternator and any circuit can be connected, and the system can be worked at two different electromotive forces if necessary. The primary object of this arrangement, however, is to enable a machine to be thrown into circuit rapidly, by running the machine up to full volts on one omnibus bar, and changing circuits over from the other omnibus bar, on which the other machine is running, without having to synchronise the second machine; the two omnibus bars can then be synchronised, the alternator and circuits changed over at leisure, and all the circuits and alternators run in parallel. In the outer circuit of each alternator is connected a registering watt-hour meter for measuring its output. Voltmeters are connected between both of the inner omnibus bars and the outer omnibus bar; and duplicate synchronising transformers with lamps and switches are provided between the two inner omnibus bars. In the exciting circuits are ampere-meters and regulating resistances, the switches of which are placed opposite the switches and ampere-meters of their respective machines. At present the switchboard is arranged for only two alternators and two circuits; but it can be readily extended when required, the gear for new circuits extending in one direction, and that for new alternators in the other. The two circuits are at present connected only to the rectifiers for arc lighting.

Rectifiers.—Opposite to the alternators, and standing on the same foundation block, are placed the Ferranti rectifiers for the series arc lighting (Fig. 3). These are three in number, one for each of the two circuits, and one to spare. They each consist of a self-regulating transformer, of which the primary winding is connected to the omnibus bars of the high-tension switchboard, and the secondary winding is connected through a commutator and distributing switchboard to the arc lamps. One winding is hung on knife edges in a frame, and is capable of movement nearer to and further from the other; this automatically keeps the current in the secondary winding constant at 12 amperes, varying the electromotive force to suit the number of lamps in circuit. The current from the secondary winding of the transformer is then changed, by a commutator driven by a synchronous motor, from an alternating current to a uni-directional pulsating current, which is distributed to the lamps. A small distributing switchboard is placed close to the rectifiers, by means of which any rectifier can be put on to either of the high-tension omnibus bars, and either circuit of arc lamps can be put on to any rectifier; and provision is made on this switchboard for extending the number of arc lamp circuits.

Schedule of Machinery and Plant in the Station.—In the boiler house (Figs. 1 and 3), six boilers of 10ft. 3in. mean diameter and 12ft. length, each estimated to evaporate actually 10,000lb. of water per hour; all fitted with superheaters and mechanical stokers; contractor, Mr. G. Sinclair, Leith. One duplex steam feed pump. Two electrically-driven feed pumps.

In the engine room (Figs. 2 and 3), the low-tension plant comprises eight Siemens dynamos; two have each an output of 450 amperes at 135 volts; two of 220 at 275: two of 600 at 260; and two of 865 amperes at 260 volts. The contractors for the engines, dynamos, steam and exhaust piping, feed-pumps, heaters, &c., were Messrs. Siemens Brothers and Co., who also supplied the switchboard and all connections.

The high-tension plant in the engine room consists of two alternators (Figs. 2 and 3), each having an output of 40 amperes at 2,100 volts; a high-tension switchboard; and three rectifiers for arc-lighting, with switchboard. The contractors for the whole were Messrs. S. Z. de Ferranti.

In the battery room (Figs. 2 and 3), 140 Crompton-Howell 31-plate cells, for which the contractors were the Crompton-Howell Electrical Power Storage Company.

Mains.—In the three-wire system of distribution for the northern and central districts, the electromotive force between the two outer conductors, positive and negative, is 230 volts, while that between the middle wire and the positive or negative is 115 volts. The latter is the electromotive force of the lamps on the consumers' premises, no trouble being now experienced in obtained glow lamps to work at this electromotive force, or even higher. Distributing mains are laid throughout the streets; all three wires are laid in those streets where the demand for current is large. In the other streets the positive and middle wires are laid on one side of the street, the negative and middle on the other; and a spare way is left on each side for a third conductor, should the demand require it. The distributing mains are all in parallel, and are connected up throughout the system; rings are completed wherever possible, so as to ensure equality of pressure, and to admit of disconnections being made without interrupting the supply.

Feeders.—The feeders from the station are connected to the distributing mains at 16 points. They consist of two conductors only, the positive and negative; the middle wire is interconnected throughout as much as possible, and is brought back from three districts on the system. The cables are put in parallel at the station, and one connection only is made to the switchboard. The positive and negative sides respectively of all the feeders are put in parallel at the switchboard, but any feeder or feeders can be put on a separate machine if required.

Balancing.—As far as possible consumers in each street and district are balanced against one another by connecting them alternately between positive and middle wires and between negative and middle wires; large consumers have all three wires taken into their premises, and their lights balanced against one another in a similar manner. But however carefully this balancing is done,

Digitized by Google

it is impossible to get a really accurate balance; the "out of balance" current varies from hour to hour, and even from minute to minute, and is different on different days of the week. The amount out of balance is compensated for at the station by means of the balancing machines, one of which can be put on either side of the system; the balancing during the light load is done from the battery alone. Light wires, forming potential leads or pilot wires, are brought back from all three conductors at each feeding point, and are connected to the feeder voltmeters on the switchboard; so that the pressure at the feeding points at any part of the system is directly known at the station, and the necessary regulation made for keeping the electromotive force constant. The distributing mains are brought back to the station, but are used only for the supply of light and power there; no regulation is done on the mains anywhere, except to the feeding points.

High Tension.—No high-tension feeders or distributing mains have yet been laid. They will be laid as concentric cables in ring circuits, and banked transformers in small sub-stations will be used wherever advisable, while houses in districts where the lighting is scattered will be served by isolated transformers. The concentric cables will be pulled into Doulton stoneware casings under the footways, and into cast-iron pipes under the roadways. The casings have already been laid in those streets which have been opened up for the low-tension mains, and the work of laying the high-tension mains in the southern and eastern districts is now being proceeded with.

ROADWORK.

Distributing Mains.—Practically the whole of the distributing mains are laid as cable insulated with india-rubber, heavily

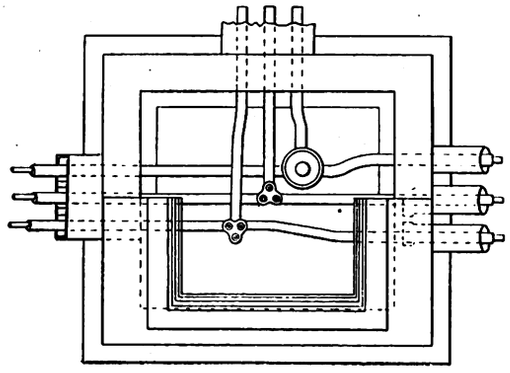

FIG. 4.

braided, drawn into Doulton stoneware casing under the footways, and into either Crompton-Davis cast-iron casing or cast-iron pipes under the roadways (Figs. 4 and 5). At all crossings, and at intermediate places on the footways, brick junction boxes are built for the purpose of drawing in, connecting and testing, and smaller brick boxes are provided at suitable intervals, where connections

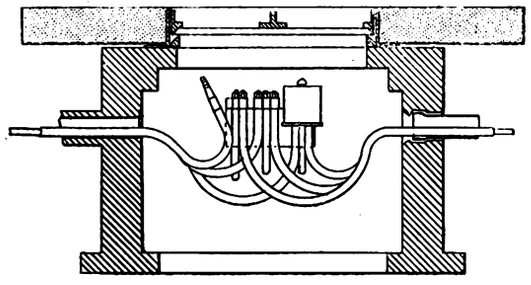

FIG. 5.

are made to consumers; but for this purpose, when space is limited, a special length of Doulton casing is provided, which is so made that it can be easily split longitudinally and removed; the house connection is then made with vulcanised joints, and the casing replaced and jointed up with a special collar and bitumen cement. The collar is provided with a socket, into which the pipe carrying the house connection can be jointed. A mark is made on the kerb to indicate the position of the service box; and the pavement is then replaced. These service boxes are found to be of great use, owing to the number of cellars under the pavement. The brick junction boxes are covered with a cast-iron frame, which is fitted with a cast-iron cover filled in with concrete, a water-tight joint being made with the frame. In most places the bottom of the box is filled in with dry rubble, so as to form a drain for any water which may find its way in; but where water has been found in the soil, the bottom of the box is concreted, and the whole made water-tight. Where it has been necessary in some places to put junction boxes in the road, they have been made as water-tight as possible, and covered with a double cover, the upper being a heavy cast-iron cover with wood blocks let into it. Boxes in the road have been avoided as much as possible, as it is found so difficult to make a satisfactory job of them. In a few places the distributing mains have been laid as bare copper strip, carried on stoneware insulators in concrete culverts.

Feeders.—Wherever sufficient space has been found under the footways, the feeders have been laid as bare copper strip, carried on stoneware insulators in concrete culverts. Across all roads, and where there has not been sufficient space for culvert, the feeders are laid in Siemens armoured cable, laid direct in the ground with a tarred board over them to act as a protection to them and as a warning to any workmen opening the ground. The cable has everywhere been laid of greater section than the copper strip in the rest of the feeder, so that the capacity of the feeder can be largely increased, and yet the resistance be kept right, by pulling in additional copper strip into the culverts, without bringing the current density up to any excessive amount in the portions laid in cable. Thus the feeders can be made to carry considerably more current than that for which they are now designed, with the same drop of electromotive force, and without either disturbing the streets or over-running any of the cables. All the feeders have been designed to have a total drop of 44 volts at full load. In the culvert the copper strip is laid in lengths of about 20 yards with a brick inspection box at each joint, so that the culvert can be easily seen by means of a lamp pushed into it, and the strip can be readily drawn out and in, as required. The joints are made by tinning the ends of all the strips, and clamping them together by a gunmetal grip box with two $\frac{3}{8}$in. bolts; at the feeding points the feeders are connected to the mains by short pieces of cable. Everywhere the culvert is kept quite straight in plan, but with a fall towards every junction box or inspection box. The strip is in no place lower than 2ft. below the level of the pavement, for it has been found elsewhere that it is impossible properly to inspect or do any work to culverts which are constructed at any great depth. There is nowhere any culvert under a roadway.

Potential Leads.—These lines, by which each feeding point is connected back to the station, consist each of three sets of wires, insulated with specially prepared paper, laid up together, and covered with the same material, a lead tube being drawn over the whole. These leads are drawn into special ways, either in Doulton stoneware casing or cast-iron pipe, laid alongside the culverts; and are joined up into one length back to the station. The joints are made in a brass tube, soldered on to the lead sheathing, and containing insulating oil; the wires are kept separate from one another by fibre discs.

Connections.—The whole of the cable connections are made by cone connectors, sweated on to the cables, and fitting into gunmetal connecting blocks (Fig. 5). The cones are all the same size for all sizes of cable, and are interchangeable; when the section of cable exceeds 0·7 sq. in., two cones are used; the taper employed is one in eleven, which makes a good fit and is yet readily disconnected. The cone connecting blocks are made in four sizes, having two, three, four, or five holes bored in them. The holes are bored conical to fit the cones on the cable connectors; and the blocks are interchangeable with one another. The armoured cables, which are all of large section, have special connectors sweated on to them, and these have either one or two of the standard conical holes bored in them; the connections to the distributing mains are then made by one or more short lengths of cable having cone connectors at each end. Enough slack is left in the boxes to allow the ends of the cables to be turned upwards; they are then connected together by slipping the connecting block on them, and the cones are drawn tight into the holes by means of a nut fitting upon a $\frac{3}{8}$in. screw on their ends. In order to obviate any trouble from end-leakage through water dripping on the bare terminals, and also to minimise the risk of short circuits through accidental contact between the blocks, stoneware caps are dropped over the connectors, and entirely cover all bare metal.

**Public Lighting.*—The streets in which there are low-tension mains are lit by electricity, by means of altogether 176 public arc lamps. The arc lamps are run four in series off the distributing mains; and each series of four is provided with a fuse, switch, and line resistance. Each lamp in the series is also provided with an automatic device, which, in the event of the lamp failing, cuts it out and introduces into the circuit a resistance equal to the lamp, so that the other lamps in that circuit are not affected. The lamps in Princes-street are constructed for a normal current of 15 amperes, and all the other low-tension lamps for 10 amperes.

In the streets, in which no low-tension mains are laid, the lamps are run on special high-tension series-circuits from the

*[Owing to some references to a coloured map, which it has been impossible to reproduce here, this paragraph has been slightly altered without, however, altering the sense conveyed by it.—ED. *E.*]

Digitized by Google

rectifiers at the station. There are at present two series-circuits, both of which are laid in all the streets lit by high-tension lamps, and the lamps are connected alternately to each circuit. The circuits are laid as concentric cable drawn into cast-iron pipes, the outer conductor of the cable being insulated. There are 24 lamps on each circuit, each provided with an automatic cut-out in case of its failing to act; and also with a switch in the pillar, by which it can be entirely disconnected from the circuit if necessary, while the switch is so made as to complete the circuit for the other lamps.

In arranging the circuits for the arc lamps, care has been taken to put alternate lamps on separate circuits in all streets, whether run from the distributing mains or from the series circuits. This minimises the risk of any street being left in darkness by the failure of any circuit, and also allows half the lamps to be switched off at or about midnight, still leaving the streets well lighted. The arc lamps are of Crompton-Pochin type, and are fitted with 18in. spherical globes. They hang from the bracket of a cast-iron pillar, the centre of the globes being 23ft. above the level of the pavement. In Princes-street the lamps are about 45 yards apart, and are on one side only of the street. In the other parts of the city the lamps are about 60 yards apart, and are placed alternately on the two sides of the street.

No contractor was employed for the roadwork or laying of the mains; the whole of this work, including the erection of the arc lamp posts, was carried out by the resident engineer, Mr. E. W. Monkhouse, with his own staff of workmen. The armoured cables were supplied by Messrs. Siemens Brothers and Co.; the unarmoured cables by the Henley's Telegraph Works Company and the India-Rubber, Gutta-Percha and Telegraph Works Company, Silvertown. The potential leads were supplied by the British Insulated Wire Company. The stoneware casing was manufactured by Messrs. Doulton and Co., and the cast-iron work by Messrs. Maclaren and Messrs. Shaw and Co. of Glasgow. The copper strip was supplied by Messrs. Bolton and Co., of Oakamoor Works. The posts for the arc lamps were designed by the Edinburgh School of Art, and the castings were made by Messrs. Mackenzie Brothers of Edinburgh. The whole of the arc lamps were supplied and fixed by Messrs. Crompton and Co., of Chelmsford, who also supplied the cable-cones and connectors.

In this account of the electric lighting of Edinburgh the author has endeavoured to describe the arrangement of the plant and mains, and any details in their design and construction which may be of interest without discussing general principles or the advantages or disadvantages of any individual system. Having himself had the good fortune to be connected with this particular work from its earliest stage to its opening, he desires to express his deep indebtedness to Prof. Kennedy for permission to prepare the present Paper and to use the drawings from which the diagrams have been enlarged, and also for his suggestions and assistance, without which it would have been impossible for this Paper to be laid before the Institution.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *October 26, 1895.*

Electrically Annealing Armour Plates.—At the meeting of American Institute of Electrical Engineers on Wednesday, one of the two Papers read was by Mr. Herman Lemp, junr., on a method of local annealing by means of the electric current which has been applied in United States naval work. The method consists in passing an alternating current, by means of two copper contacts kept cool by water circulation, through the portion of a Harveyised plate which it is desired to anneal in order that a hole may be pierced. The current employed is usually of 10,000 amperes, or equivalent to 40,000 amperes per square inch of surface; it is gradually increased and decreased, the operation generally taking seven minutes all told. An extension of the method has been applied to annealing gun shields in order that gun openings may be cut in them; in this case the copper contacts are moved along the line of the opening to be cut. The generator employed for this work is a separately-excited alternator with a maximum capacity of 100 amperes and 300 volts and a frequency of 50 $\sim$. A special converter is used, and a reactive regulator, which is made automatic in its action by a very simple method.

The Rating and Behaviour of Fuse Wires.—The second Paper read was by Prof. W. M. Stine and two of his students, giving the result of an elaborate series of experiments on fuse wires. The Paper severely condemned most of the commercial forms of porcelain fuse blocks, principally on account of the short lengths of fuses which their use involves. It was found that the rating of fuse wire is of little or no value unless lengths are also specified. The Paper speaks very favourably of the use of copper wire for fuses, and recommends that copper fuses in cylinders of insulating material be used on electric lighting and power circuits. The tests showed that copper fuses are much more reliable and sensitive than those of alloy, for the reason that after the copper has arrived at a certain temperature only a slight increase in current is required to render it fluid. The use of multiple fuses is advised, as the experiments showed that a fuse circuit of several fuses was much more reliable and sensitive than a single-fuse wire having an equal capacity.

Montreal Street Railway Convention.—The meeting last week at Montreal of the American Street Railway Association was the most successful in its existence, if judged by attendance, which numbered little less than 1,000. The commercial exhibits were also very creditable, notwithstanding the deterrent influence of the Customs. But few Papers were read, however, and these of little value. One of the Papers was a commercial one on air brakes, which argued very strongly for their adoption on American street railways, and incidentally impressed upon street railway men the absolute necessity of intelligence and skill on the part of the motorman operating them. Another Paper presented arguments in favour of creosoting street railway cross ties and line poles. It was claimed that this would result in increasing the life of the material usually employed from six or eight years to 24 years or more. It was the intention to take action at this meeting with a view to enlarging the scope of the Association; but the unexpected discovery of a deficit of about $4,000 in the Treasury resulted in deferring the matter until next year. The most notable discussion of the proceedings was on the report of the Executive Committee, recommending an amendment to the constitution of the Association whereby manufacturers and dealers in electric railway supplies could become associate members. Notwithstanding the fact that the recommendation was signed by every member of the Executive Committee, it was defeated after a spirited discussion by a vote of 87 to 11.

CORRESPONDENCE.

ALTERNATE CURRENT WAVE FORM DELINEATION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to the letter of Messrs. Barr, Burnie and Rodgers, published in *The Electrician* of October 18th, I think it right to say that in making my claim with regard to the method employed by these gentlemen I had not any intention of putting their good faith to question, nor of depreciating the merit due to them for the construction of their apparatus, which shows, I am glad to observe, a serious advance, from the point of view of insulation. I am very much obliged to these gentlemen for the good grace with which they have accepted my claim.

As to the remarks of Prof. Hicks in *The Electrician* of October 25th on this point, they would only be justified if Messrs. Barr, Burnie and Rodgers' apparatus enabled one to see the entire curve at a glance. But these gentlemen have taken pains to say that this is not the case, and that being so, it is as easy to follow the tracing with a pencil on a drum as on a screen. To see the entire curve it must be described in at least $\frac{1}{10}$th of a second, which could not give accurate results unless the galvanometer had a period of vibration equal at the utmost to $\frac{1}{200}$th of a second. Prof. Hicks, doubtlessly, did not think of this important condition, which led me to adopt a clockwork.

I may add, moreover, that if it is a question of projecting the periodic curve on a screen I can also claim priority, for I showed to the Académie des Sciences two years ago (March 6th and April 10th) the first instrument (the telephonic method

Digitized by Google

of Fröhlich being, as I have shown, quite erroneous) which enabled one to obtain this result with accuracy and without the aid of a "contact brush." This apparatus, called an "oscillograph," has worked in a most satisfactory manner for several months in a large factory at Paris, and I published, at the Chicago Congress, curves obtained by this device, of which few electricians seem even now to admit the possibility. It will, doubtless, be reinvented by other gentlemen in a short time, and it will then, we may be sure, be found excellent.—Yours, &c.,

A. BLONDEL.

MAGNETIC FORCE AT ANY POINT IN A PLANE CIRCUIT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The mistake in my second formula was really made, as it has been said by Mr. A. Russell. I am sincerely obliged to him, and to your other correspondents, for having detected it. I must say I do not regret it when I see the number of interesting letters it has suggested.—Yours, &c.,

Brussels, November 2, 1895. OSC. COLARD.

SHAPE OF E.M.F. CURVE AND IRON LOSSES OF TRANSFORMERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of October 25th a letter appeared from Mr. Alfred Hay, in which attention was drawn to an obvious error in Mr. C. P. Feldmann's article on the above subject, contributed to *The Electrician* of October 18th.

Perhaps I may be allowed to point out another mistake which proves equally disastrous to Mr. Feldmann's results. If reference is made to Figs. 4 and 5, it will be seen from a short study of the curves that Mr. Feldmann has *reversed the direction of the* B-H *cycle*. As a necessary consequence of this error it is evident that if "the curve of total E.M.F. E_1" (Fig. 1) represents the applied P.D. (as it assuredly does), then the current wave is about 180deg. out of phase.—Yours, &c.,

October 29, 1895. STANLEY BEETON.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I plainly admit the blunder attributed to me by Mr. Alfred Hay in your last issue, but am at a loss to understand how it could pass my attention. Mr. Evershed's valuable series of articles was well known to me, and I referred to it at several places of my book upon the calculation, testing and working of alternating-current transformers. The salient points of my article—*i.e.*, the splitting-up of the hysteresis curve into its components and the evaluation of the component idle currents and E.M.F.'s—remain intact, and are not affected by the error into which my mathematics have fallen.—Yours, &c.,

Cologne, October 27, 1895. C. P. FELDMANN.

LEGAL INTELLIGENCE.

Burne-Jones v. New and Mayne.

In the Chancery Division on Friday last, before Mr. Justice Kekewich, Mr. Renshaw, Q.C., said that he had a motion in an action in which Sir E. Burne-Jones, who was the plaintiff, moved for an injunction to restrain the defendants, Messrs. New and Mayne, from working electrical machinery at Rottingdean in such a manner as to cause a nuisance to the plaintiff by noise, vibration and smoke. The defendants had submitted to a perpetual injunction and to pay the costs. Operation of the injunction was ordered to be suspended in order to enable the defendants to carry out certain alterations with a view to abating the nuisance complained of.

Electric Traction in Switzerland.—A Syndicate, having its seat at Zurich, has applied to the local and federal authorities for the concessions of several electric metre-gauge road railways to be constructed in the cantons of Zurich, Argovie, and Zug, the plans and designs having been prepared by Dr. Du Riche Preller, M.I.E.E.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

SPECIAL NOTICE.—The 1895 (thirteenth) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is READY. In addition to the old well-known features of the book, which are brought up to date, a quantity of new and useful matter has been added, rendering the book more than ever indispensable to the Electrical, Engineering, and Allied Trades. Price 7s. 6d., post free 8s. 3d., abroad 9s.

The Edition for 1896 is in active preparation, and orders for Advertisements and Subscriptions (5s. 9d. post free, abroad 6s. 6d.) should now be sent in. The usual circulars, &c., will be sent out in a few days.

TENDERS INVITED.—The Corporation of Derby invite tenders for the wiring, fittings, &c., for the completed portion of the Derby Municipal Technical College, at Green Hill. Tenders to Mr. H. F. Gadsby, Town Clerk, by noon on Tuesday next.

——— The Metropolitan Asylums Board invite tenders for the execution of wiring and other work in connection with the electric light installation at the Brook Hospital and Ambulance Station, Shooter's Hill, S.E., from specification, drawings, &c., prepared by Prof. A. B. W. Kennedy, which can be obtained at the offices of the Board, Norfolk House, Norfolk-street, Strand, W.C. Tenders must be in by 11 a.m. of Monday, the 18th inst. Further particulars are given in our advertisement columns.

——— The Town Commissioners of Fermoy (co. Cork) invite tenders and schemes for the public and private lighting of the district by electricity. Some further particulars are given in our advertisement columns, to which particular attention is called. Tenders and schemes have to be sent in to Mr. P. J. Lane, Town clerk.

——— The Cheshire Lines Committee invite tenders for the supply of telegraph materials, instruments, wire, &c., galvanised and zinc sheets, pulleys, bolts, screws and various other stores for the year 1896. Tenders by the 30th inst. to the Secretary (Mr. Glegge Thomas), Central Station, Liverpool.

——— The Blackburn Corporation invite tenders for steam alternators and motor alternator, switchboard and engine room connections, street transformer chambers, transformers, &c. Tenders, addressed to the Town Clerk (Mr. Robert C. Fox), Town Hall, Blackburn, by the 30th inst.

——— Tenders are invited for the manufacture and laying of a submarine telegraph cable from Puerto Montt to Punta Arenas, Chili. Conditions and specifications may be consulted at the Chilian Legation, 36, Victoria-street, S.W., and tenders must be sent in by December 5th next.

ELECTRIC LIGHTING SCHEMES INVITED.—The Battersea Vestry offer premiums of £50, £30 and £15 for the best three schemes, reports, designs and estimates for a system of electric lighting for the parish. Schemes must be delivered to the Vestry Clerk (Mr. W. Marcus Wilkins) by December 12th next.

TENDERS ACCEPTED.—The Glasgow City Improvement Trustees received eight tenders for wiring and fitting up the New Family Home, in St. Andrew-street, for the electric light. The tenders varied from £540 to £312, and the lowest, that of Mr. R. Miller, of Glasgow, has been accepted.

——— The Board of Guardians of St. Saviour's, Southwark, London, S.E., have accepted the tender of Messrs. Morris and Son for wiring the Board room and offices for the electric light for the sum of £59. 10s.

——— The Asylums Committee of the London County Council have accepted the tender of Mr. Wm. Harbrow for the erection of temporary buildings at Banstead for the sum of £13,790. It will be remembered that this tender includes the installation of a complete system of fire alarms throughout the buildings. No tender has yet been accepted by the Committee for the buildings at Colney Hatch.

——— The Dewsbury Corporation received 13 tenders for wiring the Public Baths and Library for the electric light. The figures ranged from £284 to £895, and the lowest tender, that of Mr. G. A. Steinthal, of Bradford, has been accepted.

SALES BY AUCTION.—Messrs. Wheatley, Kirk, Price and Goulty issue a preliminary notice *re* the sale by auction, at an early date, of the entire contents of the works premises at 45, Broadway, Walham Green, S.W., now in the occupation of Messrs. Russell and Co., who, as announced in a previous issue, have decided to give up business. Further particulars are given in our advertisement columns.

——— Messrs. Wheatley Kirk, Price and Goulty make preliminary announcement of the piecemeal sale of the plant, machinery,

Digitized by Google

tools, &c., at Smithfield Works, New-road, Blackwall, E., recently in the occupation of D. W. Forbes, Limited (in liquidation). Some further particulars are given in our advertisement columns.

BUSINESS FOR SALE.—Electrical engineers can obtain particulars from Messrs. Wheatley Kirk, Price and Goulty of a small electrical business for disposal in London, which would well suit a person with a small connection to add to the present business.

APPOINTMENT.—Mr. J. McF. Smythe has been appointed assistant engineer at the Blackburn Corporation Electricity Works. Mr. Smythe was formerly with the Metropolitan Electric Supply Company.

BANKRUPTCY.—A receiving order has been made against Walter Raynes Smith, described as an electrical engineer, of St. Audries, Hitherfield-road, Streatham, London, S.W.

LIQUIDATIONS.—A meeting of the shareholders in the Swan United Electric Light Company (Limited) will be held at Ediswan-buildings, 36 and 37, Queen-street, London, E.C., on December 17th next, at 1 o'clock, to receive the liquidators' account of the voluntary winding up of the Company.

——— A meeting of the members of the Cadogan Electric Light Company (Limited) will be held at 3, Lothbury, London, E.C., on December 16th next, at 12 o'clock noon, for the purpose of receiving an account of the voluntary winding up of the Company.

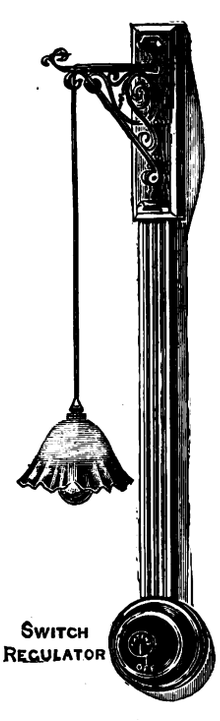
——— The public examination of J. Millington, J. Duce, J. H. Martin, R. J. Surman, and W. J. Hill, in connection with the liquidation of the New British Electric Installation Contractors (Limited) takes place at the Worcester County Court on the 20th inst., at 11 a.m.

——— It was resolved on October 14th that Hemming and Co. (Limited), electrical engineers, of Birmingham, be wound up voluntarily. Messrs. G. Thompson (Mayo and Co.) and G. W. Thompson (Flint and Thompson), of Birmingham, were appointed liquidators.

——— On the petition of the Hon. C. A. Parsons a compulsory order has been made for the winding-up of the British Steam Generator and Refuse Utilisation Company.

J. C. HOWELL (LIMITED).—It is stated that this Company is about to go into voluntary liquidation, but this step is to be taken only in order to effect a dissolution of partnership between the two Managing Directors of the Company, Mr. J. C. Howell and Mr. W. M. Meredith, in consequence of which Mr. Meredith retires from any share in the management of the business. The assets of the old Company will be taken over by a new Company of the same name, and the usual business will be continued without interruption on precisely the same lines as hitherto. The liabilities of the old Company will be discharged by the liquidator, Mr. S. F. Isitt, of 6, Old Jewry, E.C., in due course.

REGULATING SWITCH. — The accompanying illustration shows a suspended glow lamp fitted with a regulating switch on the choking coil principle. The apparatus can be mounted in place of an ordinary switch, and the current through the lamp diminished gradually by turning round the knob in the direction shown by the arrow on the switch, till the lamp filament is only a dull red. The effect of turning round the knob is to cut out windings round a ring core one by one without causing any breaks or jumps in the current, and without finally leaving the resistance of the wire itself in the circuit as when a movable core is used. These devices are very handy for persons who are in the habit of keeping a dim light burning all night in their bedrooms, but the economy of the arrangement is not, of course, very high. The makers are Messrs. Miller and Woods.



SWITCH REGULATOR

DR. LESSING'S DRY CELLS. — The St. Edmunds Electrical Engineering Works and Universal Agency, 100, Bedwin-street, Salisbury, have been appointed sole agents for the West of England for Dr. Lessing's dry cells.

ADVANCE IN PRICES.—The Telegraph Manufacturing Company (Limited) notify that in consequence of the heavy advance in the price of raw materials, discounts on electric light cables and wires have been reduced by 10 per cent. from the 4th inst. The Company also notify a revision of their arrangements as to carriage, packages, &c. A copy of the circular can be obtained from the Company's chief offices at Helsby, near Warrington, or at the branch offices in London, Liverpool, Manchester and Glasgow.

NEW WORKS.—The Coventry journals express their satisfaction at the town being selected by the Consolidated Telephone Construction and Manufacturing Company (Limited) as the centre of manufacture for their specialities. The freehold works in Bond-street, which have been purchased by the Company, are now being prepared for the special machinery and apparatus necessary for the Consolidated Company's manufactures.

LAMP CATALOGUE.—Messrs. G. Straus and Co. (Limited), of Queen Victoria-street, E.C., have sent us List "C" of incandescent lamps and accessories. The list is fully illustrated, and contains particulars of incandescents ranging from ¼ c.p. to 1,800 c.p., with voltages from 1 to 280, and from 1½ watts to 3½ watts per candle-power. A special classification is given of 3½, 2½ and 1½ watt lamps, for which long life and high efficiency are claimed. Particulars of low candle-power or battery lamps for small accumulators, for decoration, dental, surgical or microscopic purposes, of high candle-power lamps, high-voltage lamps from 8 c.p. upwards, of fancy, tubular, crinkled, and other ornamental lamps for all purposes, are also included. 34 different lamp sockets are illustrated. The accessories section includes current-measuring instruments, shades, lamp-holders, switches, carbons, &c.

CASSIER'S MAGAZINE.—We have received the copy of the November issue of this well printed and beautifully illustrated magazine. Throughout the 80 pages a large number of illustrations are given, produced in a style for which the magazine is famous. The principal articles deal with the "Burning of Anthracite Culm and other Low-Grade Fuels for Steam Raising," "Mill Equipment," "Cheap Gas Power," "Electric *v.* Steam Heat," "Gaseous Fuels," "Electric Power from the Coal Regions," and "Modern Coal Handling Machinery."

HORSELESS CARRIAGES.—Mr. H. J. Knight, well-known as the inventor of the Knight Oil Engine, doubtless to bring the matter prominently before the public, permitted himself to be summoned for allowing a locomotive to be worked without a licence, in contravention of the Surrey County Council's bye-laws. Mr. Knight was riding a tricycle propelled by an oil motor, and it was contended that this came under the definition of a locomotive according to the Act. The case was, however, not contested, Mr. Knight's legal adviser recommending him to plead liability.

BANGOR.—A special meeting of the City Council was held on Friday last for the purpose of considering certain correspondence which had passed between Mr. F. H. Medhurst (consulting electrical engineer to the Council for their contemplated electric lighting scheme) and the Parliamentary agents with reference to the question of applying for a Provisional Order. Dr. Grey Edwards said that at the last meeting of the Council a resolution was passed to apply for a licence from the Board of Trade, and also for a Provisional Order. Some of them thought that they might be within the limit of time to apply for a Provisional Order within a year or two, and he thought it was also suggested that they should defer applying for an Order until the question of an electric tramway could be discussed. It seemed, however, that they must apply for both licence and Provisional Order at the same time. Although by a resolution passed on August 30th the Electric Lighting Committee were empowered to proceed with the work at once, yet some members did not agree to go further for the licence. The reason they passed the resolution to go on with the work next year was because it was necessary to provide additional light for the town. A long discussion followed, and ultimately Dr. Edward's motion that Mr. Medhurst be instructed to prepare the necessary plans and specifications forthwith, in order that tenders might be invited, was adopted.

BEXHILL (SURREY).—The Clerk to the District Council has prepared a report on the scheme recently submitted for the electric lighting of this district, and at the last sitting of the Council the report was referred to the Lighting Committee for consideration.

BIRMINGHAM.—In our issue of October 25th we stated that the Public Works Committee of the Corporation had decided to recommend the City Council to allow the Birmingham Central Tramways Company to introduce the overhead system of electric traction on their Nechells route. Numerous letters have appeared in the local Press concerning this matter, and a meeting was held in the Duddeston Ward Hall on Monday last to protest against the proposal, and Mr. Ryder, in the course of a somewhat incoherent speech, said "three widows and 26 orphan children in the Walsall and Darlaston district owed their present unfortunate position to the electric tram system. The deaths had been caused through defective wires by the electric current." In reply to this statement a letter from Mr. Alfred Dickinson (manager of the Tramways Company) appeared in Wednesday's issue of the *Birmingham Daily Post*, from which we cull the extract below :—

"There has not been a serious accident of any kind, much less a fatal accident, through the electric cars or overhead wires in the Walsall district. That there is exceptional immunity from accident is proved by the fact that the insurance company have reduced their premium to 60 per cent.

Digitized by Google

less than was charged in the first instance, and also that amount less than is still charged for steam cars. I have received letters from the coroners for the South Staffordshire district and for the borough of Walsall. These two gentlemen cover the whole of the district traversed by the South Staffordshire electric tramways. One coroner says: 'I have never been called upon to hold an inquest on any person whose death was caused by an accident on the line of the electric trams. From my experience, I have no hesitation in saying that I consider the electric trams to be far safer than steam.' The other coroner says: 'I have never held an inquest in case of deaths through accidents caused by defective wires on the overhead electric system, nor has any fatal accident caused by such wires been reported to me.'"

BRIERLEY HILL (STAFFS.).—At the meeting of the District Council on Monday last the Lighting Committee reported that they had received several communications from electric lighting contractors relative to the lighting of the district, and the Clerk was instructed to write and obtain estimates of the cost of putting down an electric lighting plant.

BRIGHTON.—The Borough Accountant's office is to be wired and fitted up for the electric light. At a recent meeting of the Electric Lighting Committee, letters were read suggesting that Bond-street, Gardner-street, Kensington-gardens, Sidney-street, Upper-street, James's-street and Bristol-road be lighted electrically, but it was resolved to reply that, until the present street lighting works were completed, the Committee were unable to consider the question of extending the electric light mains. At the meeting of the Town Council last week the Electric Lighting Committee's report was adopted.——Col. Tester, Chairman of the Finance Committee of the Town Council, was able to make the satisfactory announcement that, owing to a contribution of £2,000 profit from the Corporation's electric light undertaking, upon which he cordially congratulated the Lighting Committee, and with other small increases in their income, for the coming year they would be able to continue the 1895 rate of 1s. 7d. in the £, which was 2d. less than in 1894. Mr. Stafford, Chairman of the Lighting Committee, said he particularly wanted to point out to the Council that they were not making large profits this year out of the electric light, but if they had not made the reductions recently announced they would in all probability have made from £4,000 to £5,000 more profit. Had it not been for the profit on the electric light the borough rate would have been a 1s. 8d. instead of a 1s. 7d.

BRISTOL.—In order to encourage the use of electricity as a motive power the Electric Light Committee have decided to make an all-round charge for the supply of electric current to motors of 4d. per unit, instead of 6d., as heretofore, provided that a separate motor is fixed and no lamps are connected to it. The Committee have recently received several important applications for the supply of current, including one from Messrs. Mardon, Son and Hall for an additional 1,000 lamps, and no fewer than 2,000 additional incandescents were connected during the month of October. The electrical department is described as "extremely busy."——The extension of the electric tramway beyond the Kingswood Church in the direction of the Warmley railway station will be completed this week. From accounts in the local papers it would appear that the residents of St. George, Kingswood, and the neighbourhood are highly pleased with the electric cars, more especially as to their frequency, regularity and speed. Already there is some talk of extensions to the present line.

CAIRO.—On Saturday evening, October 26th, the official test of the electric light at the Khedival Opera House, Cairo, took place. Messrs. Nahman and Co., electrical engineers, some time back entered into a contract with the Government to light the theatre for a period of 10 years. The installation has been carried out during the past summer under the personal supervision of Mr. A. E. Levin, A.I.E.E., superintending engineer to the contractors. The Opera Committee expressed themselves as very pleased with the effect of the lighting, which is an immense improvement on the old gas system. The installation consists of over 800 incandescent lamps and 4 arcs. The latter are arranged on the exterior of the building. The stage is lighted by 226 white, 44 red, and 44 blue lamps, and complete switching arrangements are provided for lowering the lamps by means of liquid resistances as may be required for the various scenic effects. The generating plant consists of two 22-kilowatt dynamos, by Brown, Boveri and Co., belt-driven from two Robey high-speed compound engines. A small battery of Tudor accumulators is also provided to furnish current during the day for rehearsals, &c. Either half of the generating plant is so arranged as to be capable of lighting two-thirds of the lamps if required.

CANCER HOSPITAL, BROMPTON (LONDON, W.).—The Committee of this Hospital have decided to introduce the electric light throughout the hospital premises, and have instructed Mr. Morgan Williams, C.E., to prepare specifications for the work.

CAPE COLONY.—It is intended to erect an electricity generating station at Table Bay breakwater.

CARDIFF EXHIBITION.—Arrangements have been made with Messrs. Strode and Co. for an electric light installation at Cathays Park during the period of this exhibition.

CHEDDLETON (STAFFS.).—The foundation stone of a County Asylum was laid last week by Lord Wrottesley. The amount of the building contract for this asylum is £175,000, and the question of lighting the building throughout by electricity is under consideration, and this method of illumination is most likely to be decided upon.

CLERKENWELL (LONDON, E.C.).—At the last meeting of the Clerkenwell Vestry the Works Committee reported that they had refused permission to the County of London and Brush Provincial Company to drain their transformer chambers into the gullies, and had informed the Company that the drains must be carried into the sewers in the usual way, it being the surveyor's expressed opinion that risk of explosion would by this means be minimised.

CLUB LIGHTING.—The new Conservative Club at Stroud (Gloucester) is to be lighted electrically, and the contract for wiring and fitting has been given to Mr. A. Sanders, of Cheltenham.

EAST GRINSTEAD (SUSSEX).—At the meeting of the District Council on Wednesday last a letter from Messrs. Owen Lucas and and Pyke explaining their proposals for the introduction of the electric light into East Grinstead was referred to the Lighting Committee for consideration and report.

ELECTRIC LIGHTING IN THE DUTCH EAST INDIES.—Concessions have recently been granted for the electric lighting of Solkaboemie, Padang, Soerakarta, Bandong, Poerworedje, Magelang and Djokjakarta, Java.

ELECTRIC TRACTION IN JAPAN.—It is stated that three petitions for permission to lay down electric tramways in the city of Tokyo have been received by the Japanese authorities.

EXHIBITION.—A National Industrial Trades' Exhibition was opened in the east end of Glasgow on Monday. The principal portions of the Exhibition are brilliantly lighted by electricity, the installation having been put down by the Scottish Electrical Engineering Company, under the direction of Mr. Gardiner. Twenty 2,000 c.p. arcs and about 400 16 c.p. incandescents are used. The engines are by the Acme Machine Company, Glasgow, and the dynamos by Messrs. Crompton and Co.

FAREHAM.—Major Cardew's report on the state of the local wires and poles of the Electric Lighting Company was discussed at the last meeting of the District Council. The report states that the wires and poles are in a satisfactory condition, and have suffered little from decay, although they have been erected a considerable time.

FLEETWOOD.—At a special meeting of the District Council last week Messrs. B. Sykes and Murray, representatives of the promoters of an electric tramway between Blackpool and Fleetwood, had an interview with the Council. Mr. Sykes explained the route of the tramway, and said that if the promoters could come to an agreement with the Blackpool Council they would construct the line to the borough boundary at Norbreck, which could be done without a Provisional Order or Act of Parliament. If the assistance of the Fleetwood Council and the large landowners *en route* could be obtained, they would introduce a Bill in the next session of Parliament to construct the tramway from Blackpool to Fleetwood. If not, the tramway would stop at Norbreck, and they would introduce a Bill in the following session to enable them to go through to Fleetwood. The matter was discussed at considerable length, but the Council finally adopted a resolution approving of the construction of the tramways, subject to the condition that the plans, &c., were approved by them when ready.

FULHAM (LONDON, S.W.).—The Vestry recently resolved to make some experiments with incandescent gas burners, with a view to employing same for the lighting of the main streets of the parish, but at the last sitting of the Vestry, on Mr. Sayer's motion, it was decided to rescind this resolution. Mr. Sayer stated it was unwise to incur any expense in connection with improvements in gas lighting until they had come to a decision as to the adoption of an electric lighting scheme.

HAMPSTEAD (LONDON, N.W.).—At the last meeting of the Vestry the question of lighting High-street, Rosslyn-hill and Haverstock-hill, by means of arc lamps, was referred to the Lighting Committee for consideration and report. The Finance Committee reported that they had considered the question of raising a further loan for electric lighting purposes, and recommended that application be made to the London County Council for sanction to borrow a further sum of £30,000 at the lowest possible rate of interest. The engineer reported that fresh applications for current were coming in in a most satisfactory manner.

HUYTON-WITH-ROBY.—At the last meeting of the District Council it was decided to oppose the application of an electric lighting company for a Provisional Order.

ISLINGTON (LONDON, N.).—The Electric Lighting Committee recently invited the Prince of Wales to formally open their electricity generating station, but at the last sitting of the Vestry it was stated that His Royal Highness would be unable to perform the ceremony.

Digitized by Google

LIGHT RAILWAYS.—Mr. C. T. Ritchie, President of the Board of Trade, Earl Dudley, and Sir Courtenay Boyle are making a tour of inspection of the various light railways in Belgium, with a view to obtaining information to be laid before Parliament at an early date on the subject of the construction of light railways in this country.——The Denbigh Town Council and the Merionethshire and Carnarvon County Councils are considering the question of constructing a light railway on the Holyhead-road from Corwen to Bettwycoed.

LLANDUDNO.—At a meeting of shareholders in the Great Orme's Head Marine Drive Company on Tuesday it was resolved to sell the Company's rights in the Marine Drive to the Manchester Edison-Swan Company, at a price to be agreed upon, for laying an electric tramway round the Great Orme. It is stated that the Company intend applying to the District Council for sanction to make a connecting line along Gloddaeth-street and North-parade past the Happy Valley, so as to make a circular tour of about seven miles in length.

LONDON COUNTY COUNCIL.—At the weekly meeting on Tuesday several notices under the Electric Lighting Acts and Orders were agreed to. A notice from the St. James's and Pall Mall Company for sanction to lay mains across Carnaby-street, in Ganton-street, King-street West and Argyll-place, W.—the Highways Committee stated that, according to plan, the Company proposed to cross Regent-street, which is outside the Company's area of supply. It was, therefore, agreed to give the required sanction on condition that it shall apply only to those works which are within the Company's area of supply.

LONDONDERRY.—The Corporation have approved the report of the Lighting Committee, recommending that the erection of electric lamps for the Harbour Commissioners for cattle inspection purposes be proceeded with.

MILL LIGHTING IN INDIA.—The *Indian Textile Journal* states that during the year ended September 30th electric lighting has made considerable progress in Indian mills, but not in the manner at first anticipated. Overtime and night and day working have made very little progress among cotton mills, but as certain parts of many mills are imperfectly lighted in the morning and evening, a small electrical installation has proved of value in ensuring adequate light during the whole of the working day. Among jute mills the high price of the gas and the conditions of insurance renders the electric the only suitable method of lighting.

NEWPORT (MON.).—The local gas company are in high dudgeon at a notification received from the Corporation intimating that it is the latter's wish to dispense with 50 or 60 gas lamps in the area now supplied with electric light. The gas company call upon the Corporation to light up certain waste spaces in order to bring up the consumption of gas to a standard quantity. The Corporation are seriously considering the desirability of dispensing with gas altogether for public lighting.——At the last meeting of the Governors of the Intermediate and Technical Schools the recommendation of the Building Committee that the whole of the schools should be lighted electrically was agreed to.

NOTTINGHAM.—At the County Court on Tuesday last Mr. Joseph Blackburn, electrical engineer, of Gresham Works, Nottingham, was successful in an action claiming from a late employé named Slack the sum of £5. 16s. 2d. for "overpaid wages."

PETERBOROUGH.—The Lighting Committee of the Town Council recently presented a report on the lighting of the town by electricity. The report recommended the adoption of a scheme which would involve an initial expenditure of £20,000. At the last meeting of the Council the report was, after discussion, referred back to the Committee for further consideration and report.

PRESENTATION.—The employés at Messrs. Crompton and Co.'s Lillie-road works, on October 31st, presented Mr. D. Heap with a handsome set of carvers on his vacating the position of works manager to take up another appointment. The presentation was made in feeling terms by a member of the staff, and Mr. Heap expressed his sincere appreciation of the gift.

REIGATE.—Mr. F. H. Medhurst has been appointed consulting electrical engineer to the Town Council.

SALE.—At the meeting of the District Council on Tuesday it was decided to apply for a Provisional Order.

STAFFORD.—The new County Council buildings are lighted throughout by the electric light, current being obtained from the mains of the Corporation. The wiring and fitting up has been carried out by Mr. W. O. Rooper, of Stafford.

ST. PANCRAS (LONDON, N.W.).—At the meeting of the Vestry last week the Electrical Engineer, Mr. S. W. Baynes, presented a report in defence of his high-voltage theory. "At this present date," he says, "the old 50-volt lamp is obsolete, and a number of first-class lampmakers are producing lamps of 8 c.p., 16 c.p., and 32 c.p. and upwards at various voltages up to 250. When commencing my duties in St. Pancras, I found that a number of premises had been wired ready for connection to the mains from the King's-road station; and I learned that no instructions had been issued to the wiring contractors as to the subdivision of the circuits so as to enable a supply to be given on a five-wire system. Experience elsewhere has shown that no service line should carry more than from 10 to 15 amperes; and it has become the rule to run the five services into the majority of the houses. In this way a potential difference of 440 volts frequently exists in the buildings; but, so far, no trouble has been experienced by the consumer from this cause. Our customers, having their premises already wired, could not readily comply with the requirements of the five-wire system, neither could we call upon them to re-arrange their wiring; but we could supply them with increased voltage, which would only need two service lines, and suit the arrangements already made." Mr. Baynes claims that his recent circular has saved the Vestry something like £5,000, inasmuch as the Westinghouse Company claim a royalty on Hopkinson's patent, and the money paid on the Stanhope-street mains did not cover the use of a five-wire system over the area supplied by the existing mains. Mr. Baynes gives the text of the Provisional Order, to prove that a pressure of 300 volts is authorised by the Board of Trade, and adds that, as required by Section 27 (*d*), the standard pressure on the mains is unaltered, and will remain so.

SWANSEA.—In December last the County Council appointed a Sub-committee to consider the question of the purchase of the local tramways. This Committee have just presented their report, which is to be discussed at the meeting of the Council to-morrow (Saturday). The report states that it is desirable that the control of the tramway system should be in the hands of the Council, who need not, however, work the tramways, but could lease the system to a company. The Committee state that one of the principal factors which has occupied their attention, and which has influenced them in their decision, is the question of introducing a system of electric traction on the lines. This is rendered desirable on account of the heavy gradients in many parts of the road. The Committee think it is the most suitable substitute for horses, and are of opinion that if this can be arranged, the success of the scheme for the electric lighting of the borough, which has recently been adopted by the Town Council, will be fully assured. The provision of a day load by keeping the machinery employed at a time when there is no demand for lighting would effect a very material reduction in the cost of electricity all round, and the working of the cars by electric traction would at once provide such a day load. The report states that sufficient electric current could be provided for working the cars at a cost which would reduce to almost one-half the amount proposed to be expended on their electric lighting scheme, and if these results are attained, electric current might be provided within the borough at a cost below that now charged for gas. There would also, it is urged, be a great saving of cost in the wear and tear of the roads. The following is an abstract of the provisional arrangements which the Committee have made with the Tramways Company:—

(1) The Corporation to purchase the tram lines, depots, &c., of the Company (exclusive of rolling stock) for £32,000, £10,400 of this sum to be used in discharging the Company's existing mortgage debt, and the balance to be expended by the Company in the purchase of motor cars for working the tramway system. (2) The Corporation to double the lines as far as possible, and to put in the necessary posts, wires, and bends, so as to make the lines suitable for electric traction. (3) The tramways to be leased to the Company for a term of 21 years on the following terms: Payment of the interest annually paid by the Corporation on the total money borrowed, with an additional ½ per cent.; provision for a sinking fund on tramway expenditure, for reconstruction and additions at 3 per cent., and 21 years; and a sinking fund on the balance, being purchase money for tramways, roadways, costs, &c., at 3 per cent., and 30 years. (4) The Corporation to supply electric current at a price to be agreed upon; and (5) the lines to be kept in repair by the Corporation at cost price, but no charge to be made for renewals.

The Committee also recommends that the Town Clerk be authorised to take the necessary steps for the promotion of a Bill in the next Session of Parliament to enable the Corporation to carry out the foregoing recommendations.

THE PACIFIC CABLE SCHEME.—It is stated that the South Australian, the West Australian, and the Tasmanian Governments have all declined to cooperate in pushing forward the Pacific cable scheme. With regard to the deputation which is to be received by Mr. Chamberlain on the subject no date has yet been fixed.

THE BERNE VOCABULARY.—*The Times* of the 5th inst. contains a long epistle from "Codex," in which is given, with the utmost possible brevity that so difficult a question will permit, the case on behalf of the official vocabulary from a purely mercantile point of view. On the subject of code telegraphy, an interesting article by Mr. F. Jones appears in the *London and China Telegraph* of September 30th last. Mr. Jones calls attention to the small use made of letter variations in coding, and recommends that its adoption would promote economy and give wider direct ranges and greater facility than figure variations. Mr. Jones recommends

Digitized by Google

the teaching of mercantile telegraphy, and the cultivation of a systematic knowledge of the subject in commercial schools and colleges, as if the sympathies of influential commercial firms could be secured "it would not be difficult to devise text books so graduated and illustrated that its principles could be easily grasped and adapted to any one of the manifold purposes to which it is applied, thus improving a mechanism to which recourse is daily becoming most necessary."

WAKEFIELD.—The Board of Guardians have decided to erect a new Workhouse Infirmary at a cost of £25,000. The building is to be lighted electrically.

WHITECHAPEL (LONDON, E.).—The Board of Works have appointed a committee to attend the forthcoming conference on the proposed regulations by the Board of Trade as to the supply of electric current.

WIMBLEDON.—Major-Gen. Carey held a Local Government Board inquiry at Wimbledon on Friday last into the application of the District Council to borrow £32,000 for the purpose of lighting the district electrically. There was some opposition to the application from the Ratepayers' Association, who were represented at the inquiry by Mr. E. J. Castle, Q.C., and Mr. Fordham Spence. Evidence in support of the proposed scheme was given by the Chairman of the Council (Mr. A. Holland), Messrs. A. H. Preece (the consulting engineer to the Council), W. H. Preece, C.B., and some ratepayers. In reply to Mr. J. Fletcher Moulton, who appeared for the District Council, the Chairman of the Ratepayers' Association (a Mr. Cooke) admitted that the local gas company had contributed towards defraying their expenses in connection with the opposition to the scheme. Mr. Preece said that for street lighting electricity was cheaper than either gas or oil. Several ratepayers present demanded a poll of the parish on the matter, to which the Council decline to concede.

WOLVERHAMPTON.—At the last meeting of the School Board, the Cookery Committee recommended the purchase of an electric cooking stove for the Walsall-street Girls' School at a cost not exceeding ten guineas, but after some discussion the Committee's recommendation was rejected.

COMPANIES' MEETINGS AND REPORTS.

Victoria (British Columbia) Electric Railway and Lighting Company (Limited).

An extraordinary general meeting of the shareholders in this Company was held on Wednesday at 8, Austin Friars, London, E.C., Mr. R. M. Horne-Payne presiding.

The CHAIRMAN said: The Trustees having, in accord with the trust deed, appointed me to act as Chairman of this meeting, I have, in the first place, to inform you that the annual drawing of bonds took place this morning, when £1,000 worth of bonds were drawn for redemption at 105 per cent. Shortly after the result of last year's working became known, and after the last coupon was paid, we immediately paid out such moneys as we were authorised to pay under the prospectus—namely, £43,000 for liabilities. Not long after doing so it came to our knowledge that a further debt of $9,000 was claimed by Mr. Dunsmuir in respect of coal delivered to the Company. This debt was not scheduled in the list of liabilities, and therefore we declined to pay it. We further declined to expend any money in betterments or part with any of the bondholders' money in any way until this had been explained. The Trustees sent a representative to British Columbia to make inquiries, and as a consequence they learnt that there existed between £8,000 and £10,000 additional liabilities which had not been disclosed in the Directors' schedule. We have refused to part with any money beyond the original amount, and the action we have taken has brought the Company to what may be described as a deadlock. Mr. Dunsmuir applied to the Court to appoint a Receiver in respect of his $9,000, and this the Court granted, but with the distinct understanding that every penny taken by the Receiver should be held in trust for the benefit of our bonds, and that all bonds and mortgages and encumbrances should be amply protected. The Court at the same time admitted that we had the right, if we so desired, to enter into possession of the property. It thereupon became the Trustees' duty to consider how best to protect your property and work the road in your interest. Preliminary negotiations have been entered into with the Consolidated Railway of British Columbia to guarantee your bonds in consideration of their receiving the surplus profits of the Company. We have asked you to assemble here to-day to give us your permission to carry such an arrangement into effect. The Consolidated Company owns bonds and debentures which were issued in England about two years ago, bearing interest at the rate of 4½ per cent., and they consequently will only guarantee our debentures to the same rate of interest. In order, however, to make up the interest to what you have been receiving, 5 per cent., it is proposed to give a quarter of a $100 Ordinary share for every £100 you have in the Company. For the purpose of effecting these arrangements, the Trustees ask your consent to the resolutions, copies of which you have received. The solicitors to the Trustees and myself are going out to British Columbia, to endeavour to carry through the arrangements set out in the resolutions as speedily as possible. I think you will agree with me that by what is proposed you are giving up nothing, but that you will be put in a better position than you are in at present. Although the first accounts are not yet to hand for the year, I may say that the receipts of the Company, notwithstanding the receivership, shows an increase of between 10 and 12 per cent. over those in the previous year.

Mr. J. HORNE-PAYNE, Q.C., pointed out that if the proposed amalgamation of the Victoria Company with the Consolidated Railway and Light Company were carried out the bondholders in the former undertaking would have not only an improved security, but a debenture which would be more marketable than now held by them.

In reply to Mr. Tremlett and Col. Mitchell, the CHAIRMAN said that if they agreed to have their bonds guaranteed by the Consolidated Company, he presumed that that Company's debentures would rank first and their own bonds next, before the share capital of the Consolidated Company. If, however, the two concerns were consolidated, the bonds or debentures of both Companies would be on the same footing in all respects. The share capital of the Victoria Company might be regarded as lost.

The resolutions were carried unanimously, and the proceedings terminated.

West India and Panama Telegraph Company (Limited).

The following report is issued by the Directors of this Company for the half-year ended June 30th last, and will be submitted to the thirty-seventh ordinary general meeting, to be held at Winchester House, London, E.C., on Wednesday next, at 12 noon:—

The amount to credit of revenue is £39,849. 18s. 6d., against £40,598. 1s. 2d. for the corresponding half-year of 1894, and the expenses have been £21,848. 19s. 8d. against £24,488. 17s. 5d., leaving a balance of £18,000. 18s. 10d., which, with £710. 1s. 7d. brought from last account, makes a total of £18,711. 0s. 5d., with which it is proposed to deal as follows:—

First Preference Shares—			
Dividend, six months to June 30th, 6s. per share..	£10,368	18	0
Second Preference Shares—			
Dividend, six months to June 30th, 6s. per share	1,400	14	0
Ordinary Shares—			
1s. 3d. per share (free of income tax).....	5,520	1	3
Balance to current half-year's account.....	1,421	7	2
	£18,711	0	5

The traffic receipts for the six months show a decrease of £241. 18s. 4d., as compared with the corresponding period.

The expenses of repairing cables during the half-year amounted to £8,849. 5s. 11d., being £2,524. 14s. less than those for the corresponding period. This decrease is due to the smaller quantity of cable used, and to the Company's s.s. "Grappler" not having been occupied so many days in effecting repairs. The "Grappler" came home in August last for the purpose of shipping a cargo of 203 knots of new cable, and has since returned to the West Indies. The "Duchess of Marlborough" still continues to lie up in London, out of commission.

The Right Hon. G. W. Balfour, M.P., resigns his seat on the Board on accepting the office of Chief Secretary to the Lord Lieutenant of Ireland, and it is not proposed to fill up the vacancy at present.

Western and Brazilian Telegraph Company (Limited).

The following is the report of the Directors of this Company for the half-year ended June 30th last, to be presented at the thirtieth ordinary general meeting of the Company to be held at Winchester House, E.C., on Thursday next, at 12 o'clock:—

The total earnings for the half-year amount to £84,936. 16s. 11d., against £77,603. 3s. 6d., or an increase of £7,333. 13s. 5d. compared with the corresponding half-year of 1894. The working expenses amount to £37,891. 9s. 6d., as against £37,953. 0s. 2d., a decrease of £61. 10s. 8d. Including the amount brought forward from 1894 (£2,846. 1s. 9d.), the balance to the credit of the revenue account is £49,891. 9s. 2d., from which has to be deducted £11,223. 10s. for debenture interest, £7,876. 10s. for the debenture redemption fund, £1,729. 18s. for income tax, and £5,000 placed to reserve fund. The Directors now recommend the payment of a dividend, free of income tax, for the half-year, at the rate of £2. 10s. per cent. per annum, as against £2 per cent. per annum for the corresponding period, carrying forward £5,803. 7s. 5d. This dividend will be payable as follows, viz., 3s. 9d. per share to the Ordinary shares, and 3s. 9d. per share to the Preferred Ordinary shares.

The position of affairs between the Government of Brazil and the Company as to the acquisition of the cables remains the same as at the date of the last general meeting. The Government, however, are taking authority to continue the authorisation for the purchase of the Company's system.

The shareholders are aware that the Amazon Telegraph Company (Limited) has recently been formed for the purpose of laying a system of cables up the River Amazon and connecting many important places on that river with Para, the northern terminus of this Company's system. The Directors anticipate that when this line is opened, in or before March, 1896, it will prove a valuable feeder to this Company.

The Directors notify that the conversion of Ordinary shares into Preferred Ordinary and Deferred Ordinary shares will be suspended on and after January 1, 1896, until further notice. The dividend warrants will be posted on the 15th inst.

Western Union Telegraph Company.

The following is the annual report of the President of the Company for the year ended June 30th, and which has been approved by the Executive Committee and ordered to be issued to the stockholders :—

The capital stock outstanding is $95,370,000.00, of which $28,850.35 belongs to and is in the treasury of the Company. During the year the capital stock outstanding was increased $550,000.00 for the purchase of telegraph lines and property of the American Rapid Telegraph Company. The bonded debt at the close of the year was as follows :—

6 per cent. bonds due March 1, 1900	$800,928 00
7 per cent. bonds due May 1, 1900	4,920,000 00
7 per cent. bonds due May 1, 1902	1,163,000 00
5 per cent. bonds due January 1, 1938	8,397,000 00
	$15,280,928 00
Less balance of sinking funds appropriations not yet used for redemption of bonds	428,720 74
	$14,852,207 26

During the year £2,100 sterling bonds, due March 1, 1900, and $14,000 building bonds, due May 1, 1902, were redeemed by the sinking fund trustees and $44,000 of 5 per cent. collateral trust bonds, due January 1, 1938, were issued in exchange for a corresponding amount of capital stock of the New York Mutual (formerly Mutual Union), International Ocean, and Gold and Stock Telegraph Companies, upon which, under leases of those companies' lines, interest was being paid at the rate of 6 per cent. per annum.

The business of the past year is set out as under :—

Surplus July 1, 1894		$7,007,633 54
The net revenues, expenses and profits of the year ended June 30, 1895, were as follows :—		
Revenues	$22,218,019 18	
Expenses	16,076,629 97	
Showing total net profits		$6,141,389 21
		$13,149,022 75
From which there was applied—		
For dividends	$4,767,733 75	
„ interest on bonds	893,821 65	
„ sinking funds appropriations	39,991 00	
		$5,701,546 40
Deducting which left surplus, June 30, 1895, of...		$7,447,476 35
The expenses of the year were—		
For operating and general expenses.....		$11,667,413 70
„ rentals of leased lines		1,578,584 64
„ maintenance and reconstruction of lines		2,202,378 66
„ taxes		429,361 53
„ equipment of offices and wires		198,891 44
Total expenses.....		$16,076,629 97

The following table exhibits the mileage of lines operated, number of offices, number of messages sent, receipts, expenses, profits and average tolls and cost per message since 1866 in periods of five years :—

—	Offices	Messages.	Receipts.	Expenses.	Profits.	Av. toll per message.	Av. cost to Co. of message.
1866	2,250	...	...	...	...	...	...
1867	2,565	5,879,282	$6,568,925	$3,944,006	$2,624,920	...	...
1872	5,237	12,444,499	8,457,096	5,666,863	2,790,233	66·2	43·8
1877	7,500	21,148,941	9,812,352	6,672,225	3,140,128	43·6	29·8
1882	12,058	38,842,247	17,114,165	9,996,096	7,118,070	38 2	25·8
1887	15,658	47,394,530	17,191,910	13,154,628	4,037,281	30·4	23·0
1892	20,700	62,387,298	23,706,404	16,307,857	7,398,547	31·6	22·3
1895	21,360	58,307,315	22,218,019	16,076,630	6,141,389	30·7	23·3

The Company acquired during the year the property of the American Rapid Telegraph Company, and by this purchase the lease of that Company at a rental of $60,000 per year is cancelled. During the year 817 miles of new pole line have been constructed, and 15,748 miles of new wire, of which over 10,000 miles are of copper, in accordance with the policy of replacing the defective iron wires on the trunk routes with copper wires. By this means two-thirds of the weight of the iron wires of the larger gauges necessary for the longer circuits is saved, with the consequent relief of so much of the strain on the poles, thus increasing their carrying capacity and making their maintenance the more economical. Besides, the smaller copper wires are so superior electrically to the larger iron wires that they can be used continuously, especially along the seaboard, through atmospheric conditions that frequently disable the best-constructed lines of iron wires. The cost of construction of new property for the year was $574,639.58, and $16,000 was paid for patents. These items were provided for from the surplus.

There is a decrease of 324,922 messages transmitted, as compared with the previous year; but an analysis of the returns shows that the Company transmitted about 600,000 more full-rate messages, and that the falling off in the total number was principally in Press messages, the newspapers throughout the country having curtailed their special despatches as much as possible during the recent depression in business.

The total expenses are practically the same as for the previous year. The increase of $178,284.46 in maintenance and reconstruction of lines includes unusual payments for Atlantic cable repairs, and for work upon important lines.

The year's business, taken as a whole, added $439,842.81 to the surplus, and is, the President thinks, gratifying, especially when it is remembered that the Company has maintained the dividend of 5 per cent., and at the same time has continued to make great improvements in the working plant. With the steady revival of business which seems to have begun, and which is indicated by an improvement in the weekly test office receipts, President Eckert has every reason to believe that the current year will bring the Company a larger measure of prosperity.

A complete list of the securities held by the Company is given in an appendix.

NEW COMPANIES, STATUTORY RETURNS, &c.

AUTOMOTIVE SYNDICATE (LIMITED).—This Company was registered on October 29th, with a capital of £5,000, in £1 shares, to acquire, work, sell or otherwise deal with certain undescribed patent rights, and to carry on the business of makers of electric, steam, gas, oil or other motors, iron-founders, metal workers, metallurgists, &c. The first Directors are: Edward H. Preen, chartered accountant, Basing House, Basinghall-street, London, E.C.; M. Holroyd Smith, engineer, 161, Trinity-road, Upper Tooting, S.W., and George L. Lyons, 39, Great Tower-street, London, E.C.

ENGLISH AUTOMOBILE HORSELESS CARRIAGE SYNDICATE (LIMITED).—This Company was registered on October 29th, with a capital of £5,000, in £1 shares, to manufacture, adapt, design, purchase, sell, let on hire, or otherwise deal in locomotives, carriages and vehicles of every description, and in particular those wholly or partly propelled by oil, steam, electricity, compressed air, or other mechanical motive power, and carry on the business of mechanical engineers, carriage makers, wire drawers, metallurgists, &c.

HORSELESS CARRIAGE AND MOTOR CYCLE COMPANY (LIMITED).—This Company has been registered, with a capital of £100, in £1 shares, to carry on the business of cycle makers, engineers' machinists, &c.

IMPROVED ELECTRIC GLOW-LAMP SYNDICATE (LIMITED).—This Company was registered on October 30th, with a capital of £5,000, in £1 shares, to acquire the benefit of letters patent for "an improved form of globe for electric glow-lamps," and registered designs for same, upon the terms of an agreement dated October 25th, between Thomas H. Jones and Ferdinand Fanta (for the Company), and to carry on the business of manufacturers of, dealers in and agents for lamps, fittings, plant, outfits, tools and apparatus used in connection with the supply of electricity. The subscribers, with one share each, are: W. Ash, engineer; Leo Steinberg; William F. Smith, electrical engineer; George W. Puttnam, engineer; Ferdinand Leleux, Harold Bilberg, and George H. Taylor.

GENERAL ELECTROLYTIC PARENT COMPANY (LIMITED).—This Company has just raised its capital from £24,000 to £30,000, in £1 shares, by the creation of 6,000 new shares of £1 each.

GENERAL TRACTION COMPANY (LIMITED.)—The statutory return of this Company, made up to September 2nd, has just been filed. The nominal capital is £50,000, divided into 5,000 Ordinary and 5,000 Preference shares of £5 each. All the Ordinary and 804 Preference have been taken up, and all considered as fully paid.

MANCHESTER SUBURBAN ELECTRIC SUPPLY (LIMITED).—The statutory return to September 13th has been filed. Seven shares have been taken up out of a nominal capital of £25,000, in £1 shares, but no calls have as yet been made.

MILVER PORTABLE ELECTRIC BATTERY SYNDICATE (LIMITED).—The statutory return to September 16th has been filed. Out of a nominal capital of £20,000, in £5 shares, 3,980 have been taken up, and of these 3,020 have been issued as fully paid, while £4 per share has been called on the remaining 960 shares.

IMMISCH ELECTRIC LAUNCH COMPANY (LIMITED).—The annual return to October 12th has been filed. The nominal capital is £12,000, in 10,000 Ordinary and 2,000 Preference shares of £1 each; 8,965 of the former and 1,647 of the latter have been taken up, and all the Ordinary have been issued as fully paid. A call of 10s. per share has been made on the Preference shares.

CITY NOTES.

MEMORANDA.—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver, 30 7/16d. per oz. (Nov. 7th). Consols (2¾ per cent.) 106 3/16 – 105 15/16 for money, 106 1/16—107 1/16 for account; 2½ per cent. 104—104 1/16 (Nov. 7th). Stock Exchange Settling Days: Consols, Dec. 6th; Stocks and Shares Continuation Day, Nov. 12th; Ticket Day, Nov. 13th; Pay Day, Nov. 14th; Mining Share Carry-Over Day, Nov. 11th.

DOUGLAS SOUTHERN ELECTRIC TRAMWAYS (LIMITED).—Letters of allotment in the recent issue of capital in this Company have, we learn, been posted.

AERATED BREAD COMPANY (LIMITED).—At the general meeting of this Company last week, the Chairman (Major Bolton), in moving the adoption of the report and accounts, referred to the fact that the Company had

Digitized by Google

already installed the electric light in several of their depots, and said that, although the initial expense in comparison with gas was somewhat heavy, the electric light would undoubtedly prove cheaper in the end.

ALLGEMEINE ELEKTRICITATS-GESELLSCHAFT.—At a recent Directors' meeting of this Company the report for the business year ended July 1st last was accepted, and it was resolved to recommend at the general meeting of shareholders in December next a dividend at the rate of 11 per cent., against 9 per cent. for the preceding year. The Company report the trade outlook is very satisfactory.

ALUMINIUM COMPANY (LIMITED).—The report of the Directors of this Company for the twelve months ended June 30th, to be submitted at the ordinary general meeting to be held at the Cannon-street Hotel, E.C., on Monday next, at 3 p.m., states that their forecast as to the value of the new patents owned by the Company has been realised, and that the general business of the Company at Oldbury continues satisfactory. The accounts show a net profit of £5,376. The Directors recommend the payment of a dividend of 5 per cent. on the "A" shares, absorbing £3,000, leaving a balance of £2,376 to be carried forward. An agreement was entered into in January last with the Mathieson Alkali Company of America for the sale of the Electrolytic Alkali patents for the United States, and the Directors state that the plant has been completed and is being put into operation. The Company are to receive upon the satisfactory running of the plant the sum of £65,000 (£30,000 in cash and £35,000 in shares), besides substantial royalties calculated on the output, with a minimum sum guaranteed during the life of the patents. In October last the Company entered into an agreement with MM. Solvay et Cie., owners of the Kellner Alkali patents, for a combination of both the Castner and Kellner patents, for the mutual advantage of the Aluminium Company and MM. Solvay et Cie. Under this contract the Aluminium Company obtained the sole right to work the combined patents in England and the Colonies, while MM. Solvay et Cie. possess the sole right to work the same patents on the Continent, and the Aluminium Company receive £5,000 as an extra consideration for such agreement. The Directors have sold the Castner patents, together with the benefits of the agreement with MM. Solvay et Cie to the Castner-Kellner Alkali Company (Limited) for the sum of £125,000, payable as to £25,000 in cash and as to £100,000 in shares. It is decided to pay off the £12,000 10 per Cent. "B" Debentures, which fall due on January 1, 1896. The Directors are also making arrangements for reducing the present £6 per Cent. Debenture debt by paying off the present issue, and, if necessary, raising a smaller loan at a lower rate of interest. The Directors consider that the Company, in addition to its business at Oldbury will shortly be in possession of a large income from (1) dividends on the shares of the Castner-Kellner Alkali Company; (2) royalties to be paid by the Mathieson Alkali Company; (3) dividends on the share capital of the American Company now being formed to be allotted to this Company; and (4) from the sale of the British and Continental patents, in respect of which negotiations are now proceeding. The Directors also announce that in consequence of the important office in the Government which Mr. Gerald Balfour now occupies, he resigns his position of Chairman and Director of the Company. The retiring Directors, Lieut.-Gen. Sir Andrew Clarke, R.E., and Mr. Hamilton Y. Castner, offer themselves for re-election, as do the auditors, Messrs. Broads, Paterson and Co.

BRITISH ELECTRICAL MANUFACTURING COMPANY (LIMITED).—A prospectus is issued inviting subscriptions to a share capital of £20,000, in shares of £5 each, of which half are to be allotted as fully paid to the vendor. Payment is to be made: 10s. on application, £2. 10s. on allotment, and the balance one month after allotment, and as the necessary working capital has been guaranteed, the Directors proceed to allotment forthwith. We referred to this Company in our last issue, and it is only necessary to say that Mr. C. L. Baker, late of Cornbrook Telegraph Works, Manchester, has been appointed consulting engineer to the Company. The list of applications opens and closes this day (Friday).

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended November 3rd were £971, against £939 in the corresponding week of 1894, an increase of £32. The total receipts for the half-year amount to £15,649, against £15,750 for the corresponding period of 1894, a decrease of £101.

COMPAGNIE DE L'INDUSTRIE ELECTRIQUE GENEVE.—The report of this Company for the year 1894-1895 shows a loss of £7,680.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The estimated amount of the traffic receipts of this Company for the month of October is £2,520, against £2,101 in the corresponding period of last year.

EASTERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of October, amounted to £73,606, against £67,754 in the corresponding period of 1894, an increase of £5,854.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of October, amounted to £60,288, and to £42,584 in the corresponding period of 1894, being an increase of £17,704.

ELMORE'S PATENT COPPER DEPOSITING COMPANY (LIMITED).—The annual meeting of this Company was held at Leeds on Friday last. The Chairman (Mr. John North), in moving the adoption of the report, said that notwithstanding a drop in the average price of their finished manufactures of over £12 per ton, they had been able to wipe out the old sources of loss which were so serious during the two past years, and to make a net profit of £480. 6s. 4d. They had also to contend with determined competition, and the year had had to bear the burden of one or two low-priced contracts which had not been executed when the present Directors took office. He said that there had been a much larger turnover in the factory without any corresponding addition to the expenses, and they had also effected considerable economies. If their works had been engaged all through the year to their full capacity they would have presented a very different account. They had really made during the period under review a net profit of £1,236 on the proper basis of the Company's manufacturing operations, and they had now reached a point when it was practically impossible to do better than they had during the last six months, unless the Company had adequate capital at its command. They had no difficulty in securing very remunerative orders, and they expected to be appointed on the list of Admiralty contractors, which would greatly increase the amount of their business offered to them. They had already supplied tubes and cylinders to foreign navies, though they had not yet been directly appointed contractors to the British Navy. Referring to the method of raising further capital, the Chairman said it was proposed to extend the Company's borrowing powers. Substantial offers of assistance in the debenture issue had already been received, but the offer would in the first instance be made to the shareholders, and the Directors hoped they would respond now that the Company had passed through its difficulties, and had been established on a paying basis. The Chairman said if they could raise £30,000 they would be in a position to do a much larger business. The Chairman then referred to the proposal as to the reduction in the Ordinary share capital of the Company, and said the principal advantage to be derived would be the wiping out of the old loss, and they would then be in a position to divide at once any profits that might be made. Several shareholders criticised the report, and one of the speakers moved an amendment in favour of the appointment of a committee of inspection. The amendment, however, was lost, and the original resolution was adopted, with the suggestion (accepted by the Chairman) that the Directors be authorised to write of £11,012 standing to the credit of the reserve account by reducing assets to that extent. Special meetings were afterwards held, when resolutions in favour of raising additional capital were adopted.

GREAT NORTHERN TELEGRAPH COMPANY (LIMITED).—The traffic returns of this Company in October, 1895, were £30,400, and the total receipts from January 1st to October 31st £261,600, against £226,800 and £234,600 respectively in the corresponding months of 1893 and 1894.

LIVERPOOL OVERHEAD RAILWAY COMPANY (LIMITED).—The traffic receipts of this railway for the week ended 3rd inst. amounted to £1,046. The amount for the corresponding week last year was £884; increase £162.

METROPOLITAN ELECTRIC SUPPLY COMPANY (LIMITED).—The Directors of this Company announce the payment of an interim dividend at the rate of 3s per share for the half-year ended June 30th last.

MONTE VIDEO TELEPHONE COMPANY (LIMITED).—Warrants for the 4 per cent. dividend on the Preference shares of this Company have been posted.

SOUTH AUSTRALIAN ELECTRIC LIGHT AND MOTIVE POWER COMPANY (LIMITED).—At a meeting held at Adelaide on September 7th the shareholders authorised the Directors to present a Bill to Parliament authorising the Company "to generate, accummulate and supply electricity for lighting and motive purposes in Adelaide and other municipalities in the colony."

STOCK EXCHANGE NOTICES.—Application has been made to the Stock Exchange Committee to allow 6,000 Six per Cent. Preference shares (Nos. 14,001 to 20,000) and a further issue of 3,723 Ordinary shares of the Chelsea Electricity Supply Company (Limited) to be quoted in the Official List.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the half-month ended October 31st are £2,163, as compared with £2,171 in the corresponding period of 1894.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The transfer books of this Company are closed from the 4th to the 14th inst. inclusive. The ordinary general meeting of the Company will be held at Winchester House, E.C., on Thursday next, the 14th inst., at 12 noon. The Company's traffic receipts for the week ended November 1st, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,965.

WOODHOUSE AND RAWSON UNITED (LIMITED).—A meeting of the debenture-holders in this concern was held on Tuesday at the Cannon-street Hotel under the presidency of Mr. C. J. Stewart (the Official Receiver), who stated that the meeting was called in consequence of an order of the Court, and in accordance with the decision of the meeting in June last. At that meeting it was decided that the debenture-holders were averse to the funds realised in the debenture action being appropriated for the purpose of taking proceedings against the Directors, auditors and officers of the Company under Section 10 of the Act of Parliament. This application against the Directors originally came before the Court as the result of the public examination. A case was prepared by the solicitors who were acting for the Official Receiver and liquidator, which was submitted to the solicitors representing the Receiver, and approved by them, and was then submitted to counsel, who gave his opinion that proceedings would be successful with respect to dividends paid by the Company during certain years. The matter subsequently came before Mr. Vaughan Williams, who directed that two meetings of the debenture-holders should be held for the purpose of obtaining their votes for or against proceedings being taken against the Directors and auditors. The debenture-holders who had sent in proxies against the proceedings, and who were willing to abandon their rights, numbered 16, and represented £8,826; those proxies sent in against the proceedings, and who were not willing to abandon their rights, numbered 21, and represented £9,054; and the proxies sent in in favour of continuing the proceedings numbered 54, and represented £33,254. After some discussion the debenture-holders were requested to sign and hand in the voting papers, and the Chairman stated that the result should be reported to the Court in due course.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861—1878.

No. 913. [Vol. No. 3. XXXVI.] FRIDAY, NOVEMBER 15, 1895. PRICE SIXPENCE.

NOTES.

THE Institution of Electrical Engineers will, in all probability, shortly be tossed on the waves of a storm aroused by a singular lack of foresight on the part of the Council. Up to within the last few days, the *impasse* into which the Institution has been brought by the Council's policy of drift might have been avoided by the exercise of ordinary diplomacy. To force upon the Institution a President unacceptable to a large proportion, if not to a large majority of the members, cannot but seriously weaken the Institution. At the present moment there would seem to be nothing before us but an unedifying public washing of dirty linen; an open squabble painful to all concerned—and not least so, we feel sure, to the principal person around whom the storm will rage.

WHETHER the malcontents prove victorious or no, the Institution itself is sure to suffer, may be irreparably. Even if it be true that the *active* opponents of the Council's nominee are few in number, there is undoubtedly a widespread and exceedingly strong latent opposition to the proposed President which the Council must be sadly out of touch with their constituents not to be aware of. Of two evils choose the less, and if the great body of members decide that quiet submission to the Council's choice is the lesser evil, they will not be blameworthy. But members will have only themselves to thank for future incidents of the kind, if they do not straightway insist upon radical reform in the election of Council and increased stringency with regard to the admission of members and associates; at present both methods are farcical. The Institution would, we think, suffer a grave loss, if it were composed exclusively of *bonâ-fide* electrical engineers; nevertheless, no institution that wishes to be taken seriously ought to allow itself to be represented by mere amateurs. Let all such who take an interest in electrical science and electrical engineering take part in the discussions—preferably as honorary members—but let only those who actually belong to the profession represent it on the Council. The Council, we fully admit, have had a very hard nut to crack; but for that they are alone responsible; and it is perhaps too much to expect that one to whom they have rendered such a disservice will rescue them by gracefully retiring from the untenable position to which they have permitted him to aspire.

FOLLOWING up the admirable policy which led to the Round-Table Conference on the subject of the regulations proposed by the Board of Trade in connection with electric traction, a similar Conference on the revised electric light rules will be held at the Westminster Town Hall on Tuesday, under the chairmanship of Sir COURTENAY BOYLE. Those who are to take part in the Conference are, no doubt to a large degree, indebted for their invitation to the fact that they have presented objections to the proposed rules. But the fact that the meeting is a Conference gives to these—delegates shall we call them—a position of much greater importance than that of mere objectors. We do not exaggerate their status in any degree by calling them delegates—representatives of the electrical industry in all its departments—who have been requested to aid in the preparation of those rules and regulations which, for the sake of public safety and the good repute of the industry, should be loyally conformed to by all.

IT is evident that if the result of this Round Table Conference is a set of regulations to which all present have practically agreed, then such regulations will issue with an added weight. If, on the other hand, there should emerge a difference of opinion upon any important point between the members of the Conference and the Department, that particular regulation will require to be supported by practical and convincing reasons before the bar of public opinion. Each delegate will, in a sense, be witness as well as juryman. He has, therefore, laid upon him the difficult duty of appraising the value of his own evidence as against that of others, and in this connection it will be well for the delegate to remember that his opinion—his evidence—though largely based on experiment, it is true, really depends on an investigation often limited in character and duration, and his experimental basis may not, therefore, justify as emphatically as he is inclined to think it does, the conclusions he has reached. In other words, it does not follow that when he differs with the Board of Trade, the Board of Trade is wrong, although in forcing forward any particular regulation against the unanimous voice of practical men, that Department naturally takes a step involving grave responsibility. There is, however, every reason to anticipate that, as in the case of the Traction Conference, the meeting next week between regulation makers and regulation objectors will dissipate many erroneous notions entertained by the latter as to the wilful obstinacy of the former, and will result in a workable set of rules being imposed upon the industry.

The manufacture of carborundum, an interesting account of which is given in another column, affords a typical instance of the best class of work to which the electric furnace can be put. In this material—the very existence of which was unknown a few years ago—we have a substance that appears to be capable of formation only at an extremely high temperature, and therefore not susceptible of industrial preparation without the aid of electrical energy. The temperature which can be obtained by purely chemical means—*e.g.*, by combustion—is always limited by the impending dissociation of the products of reaction; that which can be reached by electrical methods is limited solely by the degree of refractoriness of the materials of the furnace. It may be noted that the very localisation of the heat generated by an electric furnace, which has proved an obstacle to some industrial applications, is here the very essence of the process, in that it connotes the attainment of an extremely high temperature. A point of some scientific interest is that raised by the colour of the carborundum crystals, which are said to vary from yellow to blue. This may be due to the presence of small quantities of impurities such as are believed to control the hue of many coloured gems. Synthetic experiments with small known quantities of colour-producing oxides would go far to settle the question.

Though it may be an obvious platitude to say that the chief troubles with boiler feed water arise from hardness and the tendency to incrustation on the heating surfaces, it is by no means so obvious how to soften the water and prevent the objectionable "scruff." The difficulty arises largely from the composite character of the hardness of most waters, and from the necessity for dealing with the various kinds of hardness in a different manner. Temporary hardness arises from carbonates of the alkaline earths, permanent hardness mainly from their sulphates. But, though the one will be deposited before boiling, while the other will not, they both combine to harden on the boiler plates if the feed water is not properly treated before evaporation. We confess to a rooted dislike to anti-incrustation processes which are intended to take place in the boiler itself; the practice of dosing the boiler with nostrums designed to have this effect is a half-measure at the best, and in the majority of cases it is no remedy whatever. In our opinion the mineral matter should be extracted from the water before the water enters the boiler. There is not the same objection to the use of anti-incrustation compounds in the feed-heater or the economiser, provided always that the degree of hardness is not great, and that the compound is introduced continuously and not in great gulps.

In cases where there is a large percentage of mineral matter in the water, however, it is imperative, and in most cases it is advisable, to treat the feed water in bulk before it is taken by the feed pumps. The only objection to this process has been its relatively large prime cost, owing to the necessity for capacious settling tanks; but it is evident that the magnitude of this item will depend upon the rapidity with which large volumes of water can be treated. On Wednesday last Messrs. Mather and Platt exhibited, at Adlington, a plant capable of softening water for boiler use at the rate of 8,000 gallons per hour. The apparatus is the invention of Messrs. Archbutt and Deeley; and, in its action, deals with the feed water in three stages, all of which take place in the same tank. The first stage consists in the chemical precipitation of the mineral matter—the carbonates by means of quicklime, the sulphates by means of soda ash. The admixed chemicals and hot water are well stirred into the feed water in a capacious tank, the precipitation being accelerated by rapid commotion. The second stage consists in mechanically stirring up the mud in the bottom of the tank, so as to coagulate or flake the precipitate, and thus to hasten its settling. In about an hour the solid matter will have sunk to the bottom, and the clear soft "mother liquor" may be drawn off at the surface.

For ordinary boiler work these two stages should generally suffice, as, if they are properly carried out, there can be only a trace of mineral matter remaining in solution. But where it is especially desired to prevent the deposit in pipes or feed apparatus of any slight amount of carbonate of lime which may remain in solution, the third stage may be adopted. This stage takes place while the liquid is being drawn off from the tank; and it consists in the conversion of the slightly-soluble carbonate of lime into the much more soluble bicarbonate, by the passage of gaseous carbon dioxide through the liquid. The gas is generated in a simple and cheap manner by forcing air through a coke furnace. This supercarbonation will not, of course, prevent the residual hardness from producing a proportionate and small incrustation in the boiler; but, as we have said, it may serve to prevent trouble arising in the pipes and passages leading to the boiler.

Some amusing expert evidence was given recently, during a case which came before the New Jersey Supreme Court, at Trenton. A citizen's horse had become unmanageable through receiving an electric shock while crossing the electric tramway; and it was alleged that the rails were badly bonded. Prof. Moore, of Princetown College, went forth and measured the rail resistance, on behalf of the tramway company. It worked out to 0·62 ohm per mile; which, no doubt because Prof. Moore's problems often work out to a great many ohms, he considered a very low figure indeed. It was naught to him that this resistance represented a drop of 250 volts per mile of track; it was a decimal quantity measured to two places, and that meant that it was not very big. But a Mr. Woodbridge had also measured the rail resistance, apparently on behalf of the citizen who owned the horse; and *his* answer worked out to 0·08 ohm, which in his opinion was much too high for a mile of bonded tramrail. Nothing daunted, Prof. Moore, of Princetown College, produced a model to prove "that it was easier to get a shock on a dry day than on a wet day." He had a tin pan connected to one pole of a hand dynamo, and a piece of iron, resting on some sand in the pan, connected to the other pole. When the luckless jurymen touched the pan and the iron they received a shock; but on wetting the sand the shock ceased. Notwithstanding Prof. Moore's system of experimental logic and his mathematics, the judgment was in favour of the citizen who owned the horse.

A little more than a century ago Dr. Galvani, of Bologna, convulsed the electrical world by his discovery of the convulsive twitching of a frog's leg when two dissimilar metals were placed in contact with a nerve and a muscle respectively, and then brought into contact with each other. An equally curious, and it may be an equally pregnant, observation has recently been placed to the credit of Dr. Waller. The tadpole, not the full-grown frog, has been the object of Dr. Waller's scientific attentions. "Taking a trough full of tadpoles, moving leisurely and jostling each other in all directions, and passing a moderate current, the commotion," says Dr. Waller, "is amazing; the tadpole community seems to have gone mad; a writhing mass is all that can be distinguished; but the disturbance does not take long to subside, and now all the tadpoles are fixed as if at attention, looking one way, heads to anode, so that they are traversed by a current from head to tail. . . ." A tadpolar effect is also observable with hay infusion. The "paramœcia," we are told, rudely turn their noses up at the cathode, but nevertheless swim towards it in converging lines; on reversing the current the fickle horde breaks up and goes over to the other pole. "Flagellata," on the other hand, affect the anode. "Start the current," says Dr. Waller, dramatically; "two armies assemble at the two banks—ciliata to the cathode, flagellata to the anode. . . .", cathode to right of them, anode to left of them. There is evidently more in the electrical behaviour of the lower organisms than has hitherto been dreamt of in our everyday philosophy.

Cable Interruption :—

	Date of Interruption.
Cadiz-Teneriffe	Sept. 25, 1895.

The Faure Patent in Germany.—The Faure accumulator patent in Germany expires in February next. It is expected that this will be the signal for keen competition in the accumulator trade in that country.

New Berlin-Vienna Telephone Trunk Line.—The Austrian Budget contains an item of £30,000 to be expended on a second telephone line between Berlin and Vienna, the erection of which is to commence next spring.

Electrical Treatment of Disease.—It is reported that a sum of £800 has been granted by the Paris Municipality to the Salpêtrière Hospital, for the erection of buildings in which to treat mental and nervous affections by electricity.

Institution of Electrical Engineers.—We are informed by the Secretary that the annual dinner, which was to have taken place on Friday, November 29th, has been postponed until Friday, December 13th, when H.R.H. the Duke of Cambridge will honour the Institution with his company. A circular to the above effect is being issued to the members.

City and Guilds of London Institute.—One of the most useful of the many useful functions of the City and Guilds of London Institute for the advancement of technical education is the annual examination in technology which it conducts throughout the United Kingdom. Recently we have received a copy of the report on the work of this department of the Institute during the 1894-5 session. No less than 10,293 candidates have been examined, an increase of 386 since last year; and of these, 5,824 succeeded in obtaining passes, an increase of 343 above the successes of the previous year.

Institution of Civil Engineers.—Sir Benjamin Baker, speaking recently at Leeds to a gathering of Yorkshire students connected with the Institution of Civil Engineers, advocated a modification of the charter in order that the sphere of its usefulness might be greatly extended. When the charter was first granted there were only 156 members, now they number nearly 7,000. He thought the Council should be so enlarged that the great manufacturing centres of Great Britain, the Indian Empire and the Colonies should be represented upon it.

Royal Institution.—The Christmas Course of Lectures, adapted to a juvenile auditory, will be delivered this year by Prof. John Gray McKendrick, F.R.S., Professor of Physiology in the University of Glasgow, and formerly Fullerian Professor of Physiology in the Royal Institution. The subject will be "Sound, Hearing and Speech," and the lectures will be experimentally illustrated. The first lecture will be delivered on Saturday, December 28th, at 3 o'clock, and the remaining lectures on December 31, 1895, and on January 2, 4, 7 and 9, 1896.

"The Engineer" One Thousand Guinea Road Carriage Competition.—The conditions of this competition are to be found in full in *The Engineer* of November 8th, p. 459. The judges will be Sir Frederick Bramwell, Mr. John Audley F. Aspinall, and Dr. John Hopkinson. The competing vehicles will be divided into four classes, receiving prizes of 350, 250, 250, and 150 guineas respectively. The trials are to consist of a 100-mile run out and home—200 miles in all. No speed of more than 10 miles an hour will be placed to the credit of any competitor. The limit of weight is two tons. The competition will probably take place about a year hence.

Royal Society.—The following is a list of those who have been recommended by the President and Council of the Royal Society for election into the Council for the year 1896 at the anniversary meeting on November 30th :—President, Sir Joseph Lister; Treasurer, Sir John Evans; Secretaries, Prof. Michael Foster, Lord Rayleigh; Foreign Secretary, Mr. Edward Frankland; Members of Council, Mr. William Crookes, Sir Joseph Fayrer, Mr. Lazarus Fletcher, Mr. Walter Holbrook Gaskell, Mr. William Huggins, Lord Kelvin, Prof. Alexander B. W. Kennedy, Prof. Horace Lamb, Prof. Edwin Ray Lankester, Prof. Charles Lapworth, Major Percy Alexander MacMahon, Prof. John Henry Poynting, Prof. Arthur William Rücker, Mr. Osbert Salvin, Prof. Harry Marshall Ward, Admiral William James Lloyd Wharton.

Electrical Tanning.—In the *Zeitschrift für Elektrochemie* Herr Folsing, writing on this subject, states that he has worked out an electrical method of tanning, which he considers is suitable for both thin skins and heavy hides, and only requires three to six days. The tanning pit contains 15,000 litres. Electrodes of nickelled copper are fixed to the walls of the pit, in which the hides are hung so that the current has to pass right through them. A current of 12 amperes with an E.M.F. of 12 volts is used. The colour of the leather is not quite satisfactory when commercial unpurified extract is used. The author lays stress on this, and he himself uses an oak extract (with a little hemlock extract added) which is cleared and decolorised by a special electrolytic process. When this is used he finds that the colour is exceedingly good and bright. Light cow-hides were found to require 72 hours, heavy cow-hides 5 days, and heavy ox-hides 6 days. The latter would require about a year by the old process.

Prize Offered for a Fuse Design.—The Verband Deutscher Elektrotechniker is offering a prize, consisting of a diploma and £15, for the best device by which mistakes, such as placing the wrong size fuse in fuse terminals and the interchanging of fuses except by authorised persons, shall be rendered impossible. The standard sizes of lead fuses adopted by the Verband at its last annual meeting are to be employed. These are :—

Amperes.	Distance between centres of fuse terminals in inches.	Diameter of terminal screw in inch.
50	2·8	$\frac{1}{4}$
100	3·2	$\frac{5}{16}$
400	3·8	$\frac{1}{2}$
1,000	4·4	$\frac{3}{4}$

The designs are to remain in every respect the property of the individual, and must be sent in not later than April 1, 1896, addressed to the Verband at 3, Monbijouplatz, Berlin, N., and marked with a motto. The result will be made public at the next annual meeting of the Verband.

Digitized by Google

"Chicago Times-Herald" Motor Cycle Race.—This race took place on November 2nd, but of the 90 vehicles entered only two were ready to put in an appearance, and as a delay of three weeks would enable most of the competitors to produce their machines, the race has been adjourned to November 28th. Although only two vehicles crossed the line on November 2nd, 150,000 persons turned out to see the start. By the terms of the competition the vehicles had to cover a course of 92 miles in a maximum period of 13 hours. Half-way over the course one vehicle was disabled, and the Benz motor had the race all to itself, and covered the ground in a gross time of 9 hours 30min. Its real running time, after deducting all time lost in stoppages, &c., was 8 hours 44min., averaging about 10 miles an hour gross and 12 miles an hour net. The victorious motor cycle was made in Germany. It is driven by gasolin, and when it started it contained four gallons; four additional gallons were taken in *en route*, but $2\frac{7}{8}$ths were not consumed—therefore it took $5\frac{1}{8}$ gallons to convey the machine with its four riders ninety-two miles, the total cost of fuel being less than 4s. On concluding the course, the judges carefully examined the machine, and announced that it was in excellent condition, and quite capable of repeating the journey at once. Ice was packed on the wagon to keep down the temperature, but the cylinder was not unduly heated, nor was there any perceptible heating of any of the bearings.

The Work of Technical Societies.—In a very interesting leading article on this subject in *Engineering* of November 8th, the following judicious remarks occur :—

"The stimulus of controversy and criticism is worth more than the sacrifice of the small amount of exclusive experience which is made to obtain it. Just as time judiciously spent in physical exercise is not lost, but brings its reward in heightened mental and physical activity, so the intellectual effort of unfolding and defending one's ideas finds its compensation in increased power of mind and will. The result of measuring oneself with others may not always be agreeable, but the very fact that it is not is the best proof of the necessity of the operation. To shun the trial is not only to acknowledge defeat, which may be inevitable, but also to abandon the struggle for improvement. Personal intercourse in connection with technical societies fosters the scrupulous etiquette which distinguishes the professional man from the trader. The general sense of the members is always opposed to unworthy methods of seeking and conducting business. It may be that under the stress of circumstances many would allow themselves some latitude in this respect; but the thought of the effect it will have on the estimation they will be held in by others, acts as a strong deterrent. The solitary worker has no such safeguard; he can easily present his conduct to himself in the best light, and there is no one else to be considered. The fear of public opinion may not lead to a very high type of morality, but it is world-wide and it is the basis of our civilisation. We judge our neighbours less leniently than we do ourselves, and we feel obliged to conform to the standard we set up for them, because we know they will apply it to us, and look down upon us if we fail to reach it. It is sometimes hard for beginners to be debarred from advertising themselves, but it is to their advantage in the long run that the honour of their profession should be maintained."

Electric Supply in Paris.—At a meeting of the Société Internationale des Electriciens on the 6th inst., MM. J. Laffargue and F. Meyer read a Paper dealing with the Paris central station and isolated electric plants. After a brief glance at the central stations of 1889 M. Laffargue gave a general description of the Paris central stations as they are to-day, and will be shortly. The Compagnie Edison are laying down at the Avenue Trudaine station a 900 H.P. direct-coupled Brown dynamo. The Société d'Eclairage are laying down a 600 H.P. Corliss engine driving a Desroziers dynamo, also a 300 H.P. Laval steam turbine. The Compagnie Parisienne d'Air Comprimé et d'Electricité are constructing a third station on the Quai Jemapes. The output of this additional generating centre will be 2,400 kilowatts to start with, and it will contain three 800-kilowatt 500-volt external-collector machines. The Company serving the Secteur des Champs Elysées is erecting a fourth 400-kilowatt 3,000-volt alternator, and the Company serving the left bank is at work on a 4,000-kilowatt station at Issy; distribution will be carried out by 3,000-volt alternate currents, and the plant will comprise ten 400-kilowatt alternators. M. Laffargue also showed several load curves, the total load curve of Paris showing a maximum output of 6,778 kilowatts, which takes place at about 6 o'clock. [For London, the maximum load, as given by Mr. Crompton in his Presidential Address to the Institution of Electrical Engineers in January last, was 11,600 kilowatts at 5:30 p.m. (December 24, 1894)]. During 1894 the total output of the Paris central stations amounted to 7,883,434 kilowatt-hours. According to M. Laffargue the horse-power of the isolated electric-lighting plants in Paris aggregates 25,760 H.P., including 700 gas engines of a total of 2,250 H.P. and some 500 H.P. of compressed-air motors.

Electricity in Berlin Suburbs.—There have been for some time past all manner of reports in the German Press with regard to the electrical plant about to be put down in the suburb of Berlin situated on the banks of the upper Spree. The fact of the matter, however, is that the Allgemeine Elektricitäts-Gesellschaft has already bought a large site at Wilhelminenhof for the erection of the generating plant, and acquired concessions from different authorities for the distribution of electric energy. It is first intended to run the wires out in the direction of the villages of Grünau and Köpenick, and the first portion of the machinery is already in course of construction. It is expected that by July 1st next the supply of current will be commenced. At present only two steam dynamos of 1,000 H.P. each are contemplated, but later machines of 3,000, 5,000 and 10,000 H.P. are expected to be laid down. The undertaking has in view the supply of current for power rather than for lighting purposes. There are already several industrial establishments in the district, and it is anticipated that many more will be erected when it is known how cheaply the current will be supplied. The charge for current is fixed so far as lighting is concerned at 6d. per unit, and for power purposes at 1·2d. per unit. These prices will be subject to a discount. Ignoring the discount the charge per brake horse-power-hour would then be from 1 to 1·1d., according to the efficiency of the motor. This figure compares favourably with those obtained from a large number of Berlin establishments where steam or other motive power is used, but the Allgemeine Elektricitäts-Gesellschaft hopes to still further reduce this price as the plant increases. The distribution will be overhead, and large girder poles will carry the conductors. The "drehstrom" system will be employed at a potential of 5,000 volts, and there will be transformer sub-stations in the different districts.

Current Electrical Science.—No. 10 of *Wiedemann's Annalen* contains the usual amount of interesting matter. F. Kohlrausch, than whom we could have no better authority, writes on several improvements in WHEATSTONE'S BRIDGE. He uses a long wire wound on a roller along a flat groove, the material of the roller being marble, or wood boiled in paraffin. To increase the accuracy of the readings resistances are introduced at each end of the wire, amounting to 4·5 times the resistance of the wire itself. When the inequality between the two resistances to be compared does not exceed 20 per cent., and the scale can be read to 1 in 10,000, the error of a determination does not exceed 1 in 25,000. A commutator with six blocks admits of putting in the additional resistances on one or both sides. In another Paper, which forms a continuation of previous researches, E. Wiedemann and G. C. Schmidt revel in their newly-explored field of CATHODIC LUMINESCENCE. This seems to be a most fruitful subject, and pregnant with future issues. The glowing of solids and "solid solutions" under the influence of cathode rays has, indeed, occupied considerable attention in England ever since Crookes propounded his "radiant matter" theory, but since the "luminescence lamp" has become an accomplished fact, the interest in this matter has considerably increased. The most beautiful colours observed are the red of mixed magnesium and manganese sulphates, the yellow of cadmium sulphate, the green of calcium fluoride and manganese, the dark blue of quinine bisulphate, the violet of lead sulphate, and the brilliant white of zinc sulphate, or sulphide, and cadmium iodide. The "solid solutions," in Van't Hoff's sense, containing traces of manganese sulphate in combination with other substances, vary in hue with different solvents, but not with different concentrations. Luminescence ranges over all temperatures from $-80°$C. to $+500°$C., but the intensity of the glow, and the duration of the after-glow, is greatest at the lowest temperatures. The sulphates of iron, nickel and copper extinguish the luminescence, even in small quantities. We cannot now pursue this fascinating subject any further, but hope to give the substance of other remarkable Papers on cathode rays, by Lenard and Lehmann respectively, in the next N te

THE INTEGRAL OF $r_n d\theta$.

BY W. A. PRICE, M.A.

In a Note from Mr. W. H. Everett, printed in your issue of October 4th, an expression $i\int\frac{d\theta}{r}$ was given for the magnetic force at any point in the plane of a plane circuit carrying

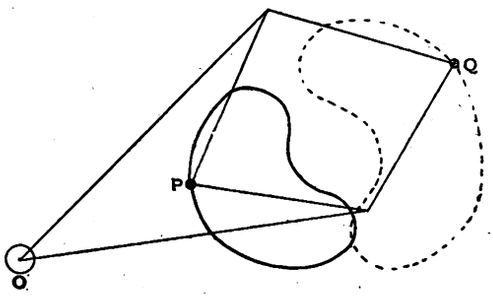

FIG. 1A.

a current of electricity i. This quantity can be measured for any point by an apparatus somewhat similar to Amsler's planimeter. Suppose, in Figs. 1A, 1B, that O is the point at which the force is to be determined, and that the full line represents

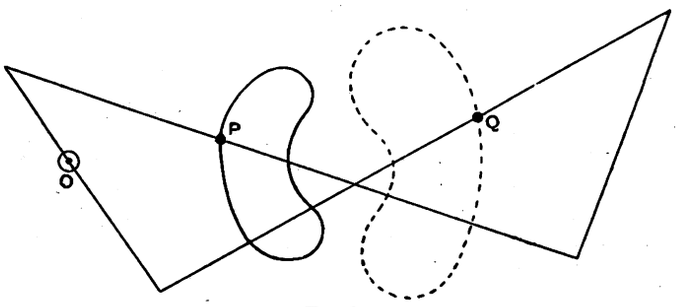

FIG. 1B.

the electric circuit. If P be carried round the full line curve, a pencil Q connected to P by Peaucellier's (Fig. 1A) or Hart's linkage (Fig. 1B) draws another curve, shown dotted, which is the inverse of the locus of P with respect to O. If $r\theta$ be the

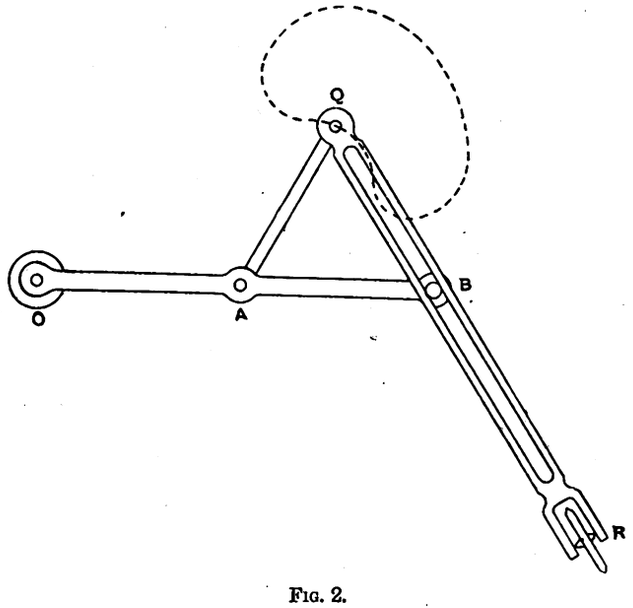

FIG. 2.

co-ordinates of P, and $\rho\phi$ those of Q with respect to O, then $\rho=\frac{a^2}{r}$, and $\phi=\theta$, and $\int\frac{1}{r}d\theta=\frac{1}{a^2}\int\rho\,d\phi$.

The value of $\int\rho\,d\phi$ can be found by an instrument constructed thus: O A B is a rigid link turning freely about the fixed point O. At A, the middle point of O B, is pivoted another link, A Q, equal in length to O A and A B; a third link, Q B R, pivoted at Q, moves so as always to pass through B, and carries a wheel at R rolling on the paper on which the

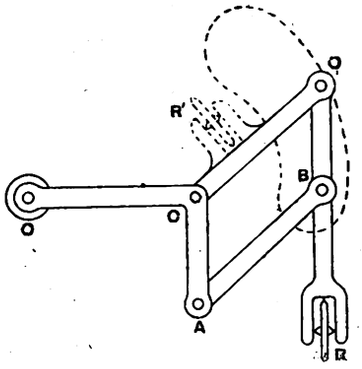

FIG. 3.

curve is drawn. The rotation of the wheel R as Q is carried completely round a closed curve measures $\int\rho\,d\phi$, and so $\int\frac{1}{r}d\theta$

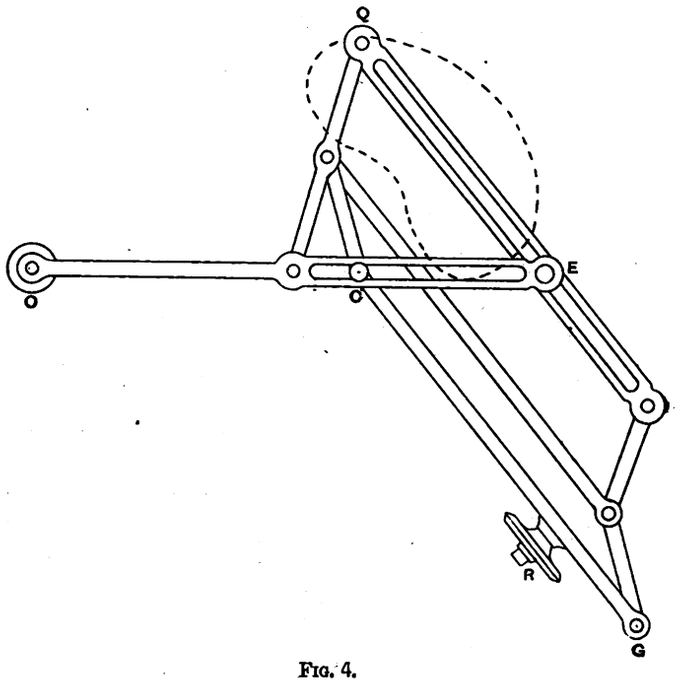

FIG. 4.

for the original curve. Other integrators performing similar operations are the following. In the one shown in Fig. 3 the

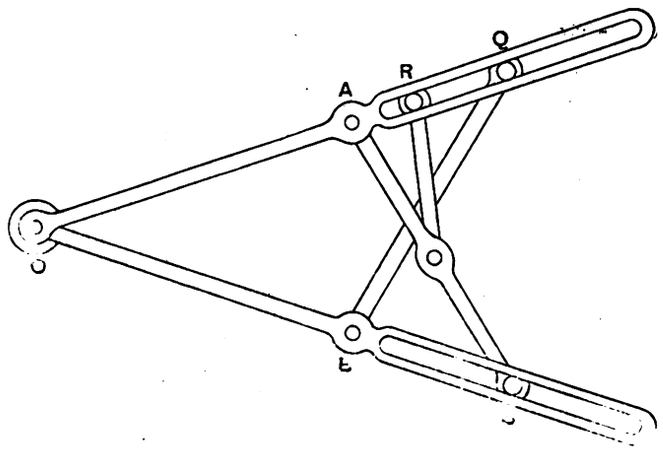

FIG. 5.

wheel at R measures $\int\rho^2\,d\phi$, $\rho\phi$ being the co-ordinates of Q with respect to O. This result is obtained much more simply by Amsler's machine, which omits the links A B and Q B B,

Digitized by Google

well as the projection C A, and places the wheel in the position shown dotted at R'.

The wheel of the machine shown in Fig. 4 gives the measure of $\int \rho^3 d\phi$. Here C is always the foot of the perpendicular dropped from Q upon O E, and C G is constrained to lie always parallel to Q E.

In Fig. 5, R is always the foot of the perpendicular drawn from S upon O Q. O S always = O Q, O A = O B = B Q = A S, and $2 . O A . O R = O Q^2$. If $\rho\phi$ are the co-ordinates of Q with respect to O, the co-ordinates R are $\frac{\rho^2}{2a}\phi$, and the curve described by a pencil at R, while Q travels round any curve, has a radius vector always proportional to the corresponding radius vector of the locus of Q.

By applying the instruments of Figs. 2, 3 and 4 to the original curve, or that derived from it by the operations of Figs. 1 and 5, the values of $\int r^{-6} d\theta$, $\int r^{-4} d\theta$, $\int r^{-3} d\theta$, $\int r^{-2} d\theta$, $\int r^{-1} d\theta$, $\int r\, d\theta$, $\int r^2 d\theta$, $\int r^3 d\theta$. $\int r^4 d\theta$, $\int r^6 d\theta$, are all obtained.

The geometrical proof of these constructions was given in *The Electrician*, page 612, Vol. XXXIII.

THE ELECTRIC EQUIPMENT OF MESSRS. SIEMENS' WORKS.*

BY ALBION T. SNELL, ASSOC.M.INST.C.E., M.I.E.E.

This is one of the largest installations in this country for supplying electric power for factory purposes, and is doubly important because tests have been made of the efficiency of the plant, and have been published in a very complete form. The area covered by the works is 6¼ acres, and of this approximately 5 acres are covered by shops and other buildings.

The author visited Messrs. Siemens Brothers' works in September, 1895, and was shown round the shops, the various points of special interest being explained to him. He is also indebted to a Paper by Mr. Alexander Siemens, read before the North of England Institute of Mining Engineers in December, 1894, for much of the information here.

Electrically, interest centres around this plant both on account of the use of continuous currents, and also because the pressure of supply is only 120 volts. This low pressure is to be explained to some extent, perhaps, because the firm's stock machines are wound for this pressure, and, therefore, it would have been inconvenient to select a higher one.

Scheme.—This plant has been designed to replace by gradual instalments 18 isolated steam engines, capable of indicating collectively 1,446 H.P., corresponding to about 1,150 B.H.P., available for driving the machinery. At the present time (October, 1895) five of the old engines are still in use; three in the gutta-percha department, one driving a portion of the cable-making machinery, and one in connection with some of the hydraulic pumps of the lead-covering presses.

The new central station has an output of about 1,200 I.H.P., which, at an efficiency of 86 per cent., as ascertained by test, gives 1,030 E.H.P. at the main switchboard. This corresponds roughly to 1,000 E.H.P. at the motor terminals, or about 900 B.H.P. on the motor shafts.

Boilers.—At the central station, shown at 12A in the plan (Fig. 1), there are five "Gunboat" type boilers, *i.e.*, double-flued multitubular boilers, each 18ft. long by 9ft. in diameter. They work at 140lb. pressure to the square inch, and have a total capacity of about 2,000 H.P. actual. They are fired by hand, and supply steam to the machinery of the central station, to the steam engines driving the gutta-percha shop, and also for heating purposes.

On the roof of the boiler house is placed a number of condensers, each capable of dealing with 25 I.H.P. These consist of two cylinders, one placed inside the other. In the annular space formed between them the steam passes from the engines, while cold water trickles down the outside of the larger and the inside of the smaller cylinder. The condensing water thus heated is used to feed the boilers and to supply the gutta-percha and india-rubber washing tanks, and the condensed steam is allowed to run to waste. This arrangement has been adopted in order to meet the special requirements of the works.

In the engine room at the back of the engines there are four sets of double-acting automatic steam pumps for supplying the circulating water, and for maintaining the necessary vacuum in the condensers. The feed pumps are placed above the boilers in the boiler house.

Engines and Dynamos.—The engine room is shown at 12 in Fig. 1. It measures 42ft. by 80ft., and contains four steam dynamos, each capable of giving a current of about 1,500 amperes at 120 volts pressure, when running at 350 revolutions per minute. The four dynamos are exactly alike, being two-pole drum armature machines of the Siemens H.B. 24/36 type, shunt-wound and fitted with switch and resistance for varying the exciting current by hand. Three of the dynamos are driven by Willans III. type compound-condensing single-acting engines and the fourth by a Belliss compound-condensing double-acting engine.

Main Switchboard.—The main switchboard is divided into two main panels, the right-hand one being coupled to dynamos Nos. 1 and 2, and the left-hand one to dynamos Nos. 3 and 4. In the centre is a commutating device by which the omnibus bars of the two panels can be put in series or in parallel, so that power may be supplied either at 120 volts to all the circuits, or to some at this pressure and to others at 240 volts, *vide* Fig. 2, in which the arrangement is shown in diagram.

The positive circuit from each dynamo passes through a main switch, fuse and ammeter, calibrated in kilo-amperes, before entering the positive 'bus bar. There is also a magnetic minimum-current cut-out, shown at E in Fig. 2, in the positive circuit of each dynamo, so that when the current from any machine falls below a certain value the circuit is opened automatically. The positive feeders are all connected through an ammeter, switch and fuse, and the returns pass through fuses before entering the negative 'bus bar. The return current is measured by three Aron meters between the dynamo negatives and the 'bus bars, and there is thus a complete record of the output of the station from day to day. Some of the departments are served with two or more positive mains on the same switch in the station, but subdivided at the shops by distributing boards.

The right-hand panel serves the lead-covering shop, fitters' shop, yarn-winding shed and dynamo shops, gutta-percha department, dynamo-testing shop, fire-engine plugs, submarine cable shop; and there is one spare circuit.

The left-hand panel serves the saw mill, office lights, india-rubber department, winding shop, stranding shop, cotton-covering shop, carbon department and instrument shop; and there is one spare circuit.

The whole of this work is remarkably solid. The 'bus bars have a cross-section of about 6 sq. in., and the several connections are of corresponding size. The main connections to the recording meters are made from copper bars 1 sq. in., one turn of which passes below the pendulum bob and forms the retarding field. The fuses are all made from flat strip white metal. Copper coupling pieces are used for making all other connections between the dynamos and the circuits.

It is interesting to notice that there are D.P. fuses on both mains, but switches on the main positives only. Also there are no switches at the distributing boards, but they are placed on the positive conductors at or near to the motors which they feed. Both arc and incandescent lamps are supplied from the same mains which supply the motors.

To prevent leakage from the conductors to the lead sheathing of the main cables, a tube of india-rubber is drawn over the ends for about 8in. or 10in. and lashed with wire to the conductor at one end, and to the lead at the other. This precaution entirely prevents surface leakage between the copper and the lead. The same plan is followed out at all the distribution boards.

Distribution System.—Each department has its distribution board, to which the current is brought from the central station by one or more cables, and is fitted with an Aron meter to record the current used, and in some cases with an

* From a forthcoming work entitled "Electric Motive Power in Practice." All rights reserved.

Digitized by Google

ammeter to enable the foreman to gauge the work being done. Each board has two 'bus bars, from which the several service circuits are taken to separate motors in the department through D.P. fuses, the switches being placed at the motors in the most convenient positions.

All the main cables are lead-covered, served with jute, and armoured with steel ribbon. The insulation between the copper conductor and the lead is desiccated jute, impregnated with bituminous compound. These cables are laid direct in the ground without any protection, and have given no trouble. The total length of wire between the switchboard and the distribution boards is a little over 6,000 yards, the area of the cross-section of the copper conductors varying from 0·25 to 1·5 sq. in. The service wires from the distribution boards to the motors are all insulated with vulcanised rubber and braided. They are carried in various ways according to the conditions, in most cases being cleated to boards run along the walls or ceilings. Casing is not generally used, except with the smaller sizes of wires.

Motors.—There are about 85 motors, varying in size from one-sixth of a B.H.P. up to 100 B.H.P., their total capacity being equivalent to about 1,500 B.H.P. The available output at the switchboard of the central station is 1,030 E.H.P., and it is estimated that nearly 900 B.H.P. could be taken from the motors at one time. But as the engines and dynamos are capable of exceeding the rated output by from 25 to 30 per cent. for short periods without any risk of injury, it is possible to increase this limit when necessary.

The motors are all of Messrs. Siemens' make, and are of various kinds to suit the requirements of the work. The majority are of the two-pole under-type, with drum armatures. The larger ones, which work under varying loads, are chiefly shunt wound. A few are compound wound for giving constant speed, but the majority are simple shunt machines. Those which run a fixed load are wound preferably in series.

All of the motors are either encased in sheet-iron boxes or are protected by iron framing covered with iron netting. This precaution serves to protect the motors from loose

pieces of iron which might be attracted by their magnets. It has the disadvantage of making the motors rather difficult of access for examination, &c.; but since they are dotted all over the works—in fact, just where they are of the most service—adequate guards are necessary under the Factory Acts to protect workmen from accidental injury.

Some of the larger motors are fitted with Meneely roller bearings, which have proved to be very efficient and economical as regards oil consumption. For example, a 40 B.H.P. Siemens 15/20 machine, running at 360 revolutions per minute, having two bearings $2\frac{3}{4}$in. in diameter by $7\frac{3}{16}$in. in length, and one $3\frac{1}{4}$in. in diameter by $6\frac{7}{16}$in. in length, requires one pint of oil per month for the three bearings. This roller bearing is shown in Fig. 3, as it is adapted to a cable stranding machine.

The starting resistances are made of German silver coils placed inside iron tubes packed up tight with fine sand, Sand is an excellent non-conductor of electricity and a good conductor of heat, so that ample radiating surface is provided, while the whole constitutes a sound mechanical device. The design is patented by the Company.

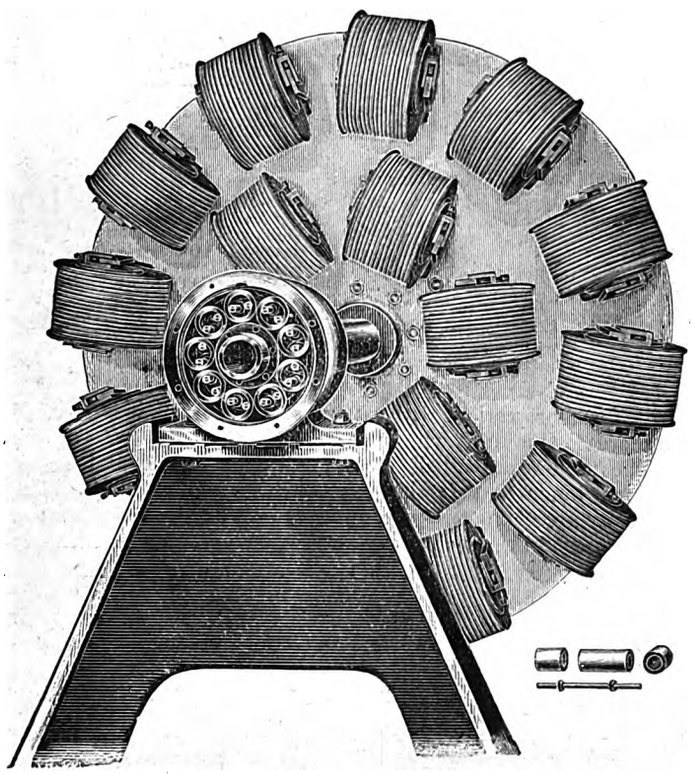

FIG. 3.—Meneely Roller Bearing, adapted to a Cable-Stranding Machine.

The motors are coupled to their work in a variety of ways, according to the position of the driven machine. In the majority of instances motors drive lengths of shafting by belting, and power is distributed by belts to several machines. This, for example, is the plan adopted in the dynamo erecting shop, where there are two motors, one of 40 B.H.P. and one of 20 B.H.P., each driving lengths of shafting. At one end of the main dynamo shop is a new vertical turning and boring machine (Fig. 4 on opposite page), built by Smith and Coventry, which will tool a circle 18ft. in diameter, with 6ft. between the bed plate and tool bridge. The table is 12ft. in diameter and revolves on an annular race in addition to its spindle; its motion is consequently very steady and free from vibration. An adjustable foot-step bearing is provided for raising the table from the annular race when it is desired to run the table at a quick speed. The table is driven by spur-gearing, the large wheel being cast with the table. The main driving gear consists of a 7-stepped pulley with back gear so arranged as to give 21 changes of speed to the table. The feed gears are driven by a friction gearing, by means of which any rate of feed can be given to the tools up to $\frac{5}{8}$ths of an inch. The massive cross slide is hung from screws in the main uprights, and can be raised or lowered by power. The tool-bars are counterbalanced so as to make them easily worked by hand. Both tools are under the control of the workman from either side of the machine. The total weight of the machine is 46 tons, the cross slide with tool-holders accounting for 12 tons. This tool is driven by a separate 5 H.P. motor, but in ordinary working it is found that about 4 H.P. is sufficient. The motor is coupled by belting to a countershaft, from which the various motions are derived by other belts. Two of the travelling cranes in this shop are each served by a single motor, from which the several motions are driven through gearing controlled by hand chains hanging from the bridge. The third travelling crane has three motors, one for each motion, the whole of the switching being controlled by chains.

In the fitters' shop there is a large shaft lathe, driven by a motor, which is coupled through a speed-reducing gear enclosed in an oil-tight box to a countershaft, whence the lathe is driven through belting and coned pulleys in the usual way, the motor being placed above the machine on an adjacent gallery. A vertical driller has the motor placed on top of the pillar, and is geared through spur gear and belting. A shaper has the motor laid on the ground behind the machine, and coupled through a box gear and belting. A portable emery wheel has the motor belted direct to the spindle of the bob. In the saw mills, the 40 H.P. motor which drives the main shaft by belting is erected on iron brackets fixed to the wall,

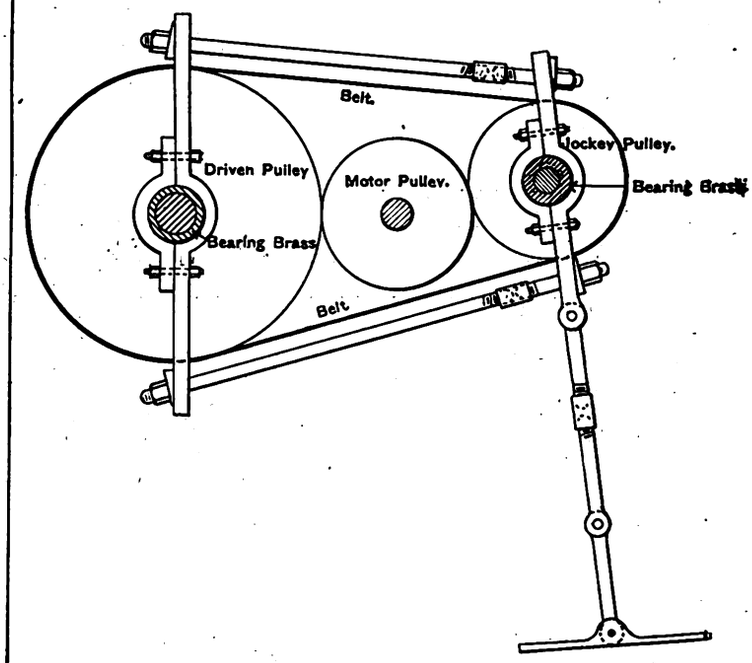

FIG. 5.—Friction Gear in use with Motors.

about 8ft. above the floor. A hoist, capable of carrying a load of two tons, used for serving the various floors of one of the main buildings, has the motor erected at the top of the well, and the switching gear is in the cage, connections being made by a flexible conductor. In the rubber department the incorporating rolls are driven in pairs by 40 H.P. motors through spur gear. Two callendering machines for rolling sheet rubber are each driven by a 15 H.P. motor through a double-threaded worm and wheel running in oil, while the raw rubber washing rolls are driven by a 40 H.P. motor through spur gear connected to a horizontal shaft coupled to each machine by means of a clutch gear. Two incorporating rolls, used for mixing the vulcanising and separating materials with the rubber, are driven by friction gear of special interest. The arrangement of the pulleys is shewn diagrammatically in Fig. 5. The motor pulley is built up from compressed paper, and both driven and jockey pulleys are well finished in cast iron. The belt serves to produce the pressure between the driver and driven pulleys, and to prevent the side thrust on the motor shaft. The device works very sweetly, and should find favour where motors are in use.

Looking at the motors and gearing as a whole, it is necessary to bear in mind that the alteration from scattered steam

Digitized by Google

engines to electric motors was made gradually, and that it was not possible to adopt some of the improvements which would be advisable in laying out new plant. It is possible, therefore, that in some cases it would be more economical to use separate motors for machines which are now driven off shafting. It must also be borne in mind that many of the motors have been taken from stock, and have not been specially designed for the work.

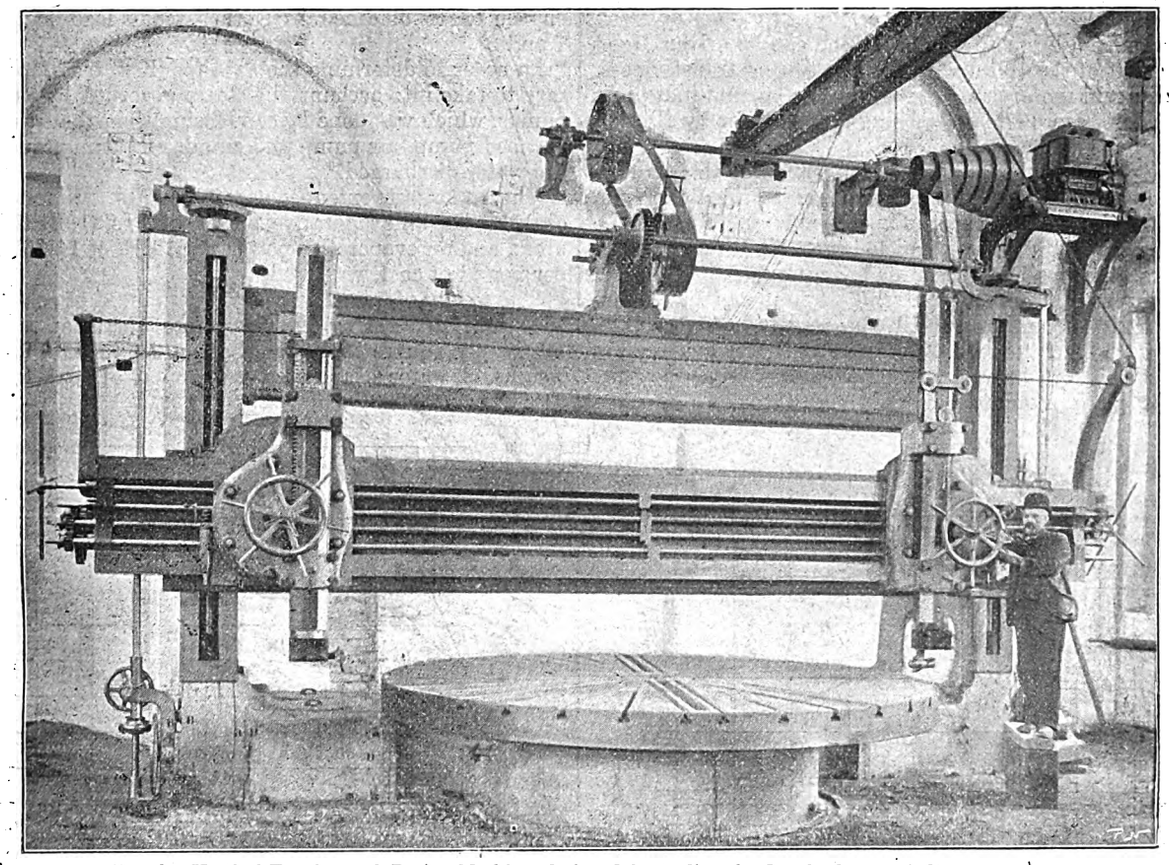

FIG. 4.—Vertical Turning and Boring Machine, designed for tooling the fly-wheel type of alternators, &c.

An interesting detail, showing the adaptability of electric power for factory work, is found in a series of plug contacts arranged about the buildings to serve a portable fire engine with electric pumps. This fire engine is built in the regular style as regards outer appearance (*see* Fig. 6), and is capable of throwing a 1in. jet of water 80ft. high, or two such jets about 65ft. The plugs are built in iron columns, and look like hydrants.

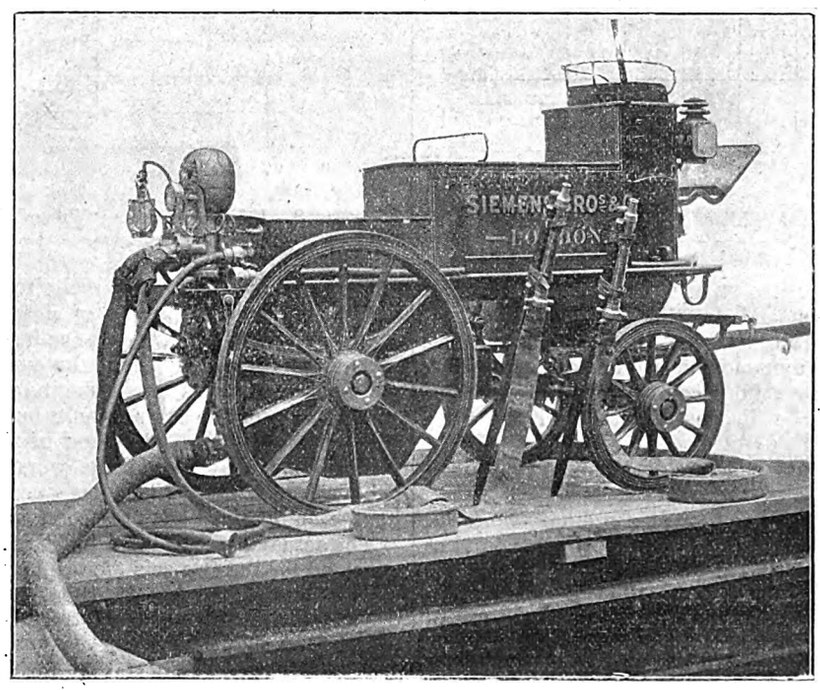

FIG. 6.—Electric Fire Engine.

The testing shop is a splendid example of how electrical testing should be carried out, and affords all the facilities for any class of testing. The plant comprises four motors, each of 75 B.H.P., belted to line shafting, one motor of 100 H.P., and four

Digitized by Google

of 85 H.P. each. It is therefore possible to get almost any combination of power for driving dynamos, and the speed can be adjusted to a nicety, and maintained constant for any required period. The author knows of no testing shop which presents quite the same facility in this respect.

There is also a large alternator, which can be driven direct from the shaft of the 100 H.P. motor, for testing transformers, alternate-current motors, and for calibrating current indicators and voltmeters, any periodicity being arranged for by altering the speed of the driving motor.

Working.—Owing to the gradual conversion of the plant to the central electric power station system, it is difficult to form a comparison between the cost of power now and that at the commencement of the change which began on June 20, 1892. But Messrs. Siemens Bros. have made very exhaustive tests of the cost of power supplied from the station, and have been public spirited enough to publish the results in a very complete form. It is interesting to notice that the old engines were served by ten stokers and nine engine drivers, whilst the electric plant requires now only eight stokers, of whom

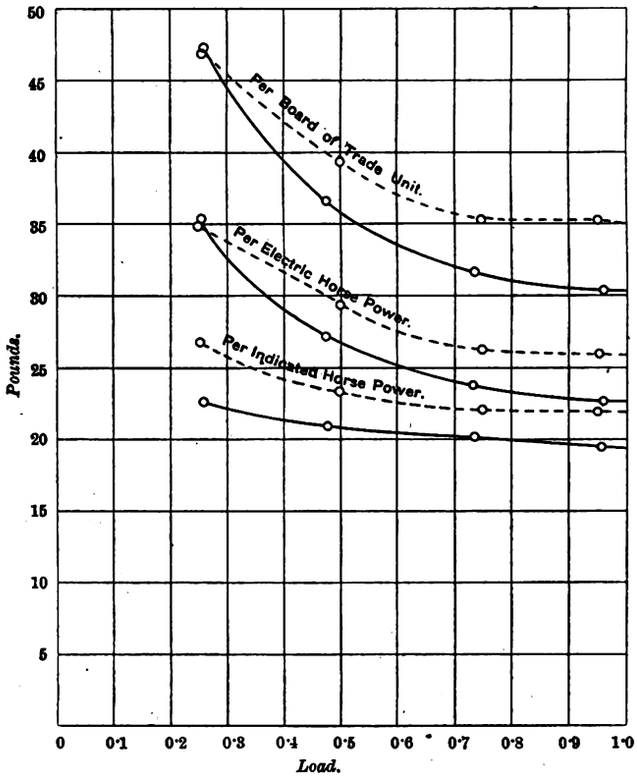

FIG. 7.—Steam Consumption. Willans' Set ————————.
Belliss' Set - - - - - - - - -.

three attend to the old boilers still in use, and five engine drivers, three of whom attend to the remaining isolated engines. The electrical part of the machinery is controlled by one electrician and one dynamo and switchboard attendant. When the arrangements are fully completed the remaining old auxiliary boilers will be dispensed with, and a further reduction in the staff will be effected.

The tests were carried out under the direction of Dr. Eugen Obach.

The boiler tests extended over a month of ordinary working. In the first place, the weight of steam generated per pound of fuel was ascertained, when the plant was supplying power both for driving the motor and for lighting the shops. Then the weight of the steam required per Board of Trade unit delivered to the distributing boards was found by exhausting the steam from each of two out of the four engines successively into the main condenser, and measuring the overflow from the air pump, care being taken that no water entered from other sources. This was determined for each engine under the conditions of quarter, half, three-quarter, and full load, and also when running on the ordinary day load. And further, a set of tests was made to see whether the steam consumption per Board of Trade unit was the same under a varying day-load as under a perfectly steady load giving the same average output. This was found to be the case, the point obtained from the day-load test falling exactly on the curve obtained from the steady load tests (*see* Figs. 7 and 8).

In order to determine the data for these tests, it was necessary to take into account the steam absorbed by the auxiliary pumps, which was done by condensing the exhaust steam from the feed pump, air pump and circulating pump, and weighing the water discharged.*

The boiler tests extended over 988 hours. Nixon navigation coal, having an evaporative power of 14,221 British thermal units, and an evaporative power at 212°F. of 14·65lb. of water per pound of coal, was used.

The weight of water evaporated per pound of coal (including coal used in lighting the fires) into steam at a pressure of 127lb. per square inch was ascertained to be 8·923lb. The weight of water evaporated per pound of coal from and at 212°F. was 10·083lb.

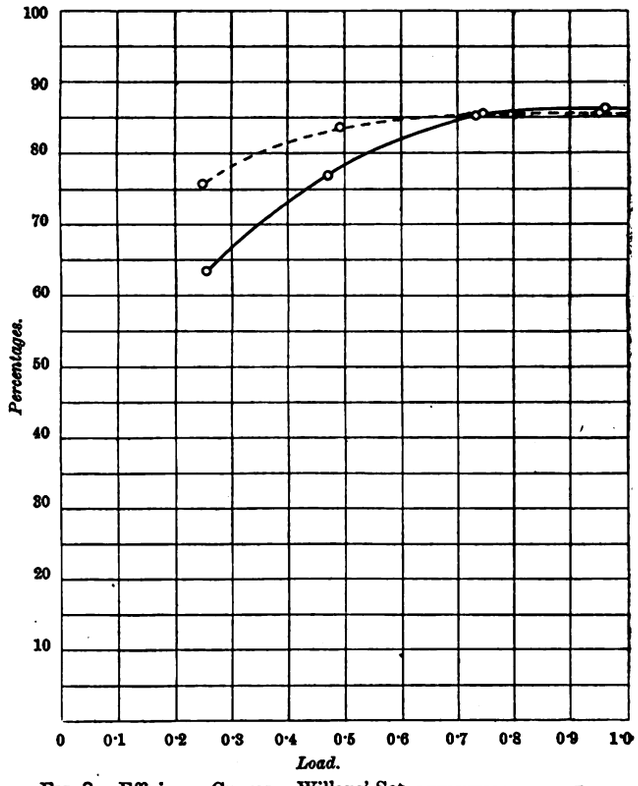

FIG. 8.—Efficiency Curves. Willans' Set ————————.
Belliss' Set - - - - - - - - -.

Experiments were also made to measure the steam consumption of the two types of steam dynamos when running on a steady load, viz., resistance frames.

The results are shown in the curves in Figs. 7 and 8. It will be seen that the Belliss engine consumed more steam than the Willans for the same output, but it must be borne in mind that this engine was the first of the type built by Messrs. Belliss, and that it had the worst position as regards the exhaust. Mr. A. Siemens has since stated that better results have been obtained with a second engine.

The actual cost of a Board of Trade unit has been carefully prepared for the two sets of steam dynamos for a period of six months ending October 31, 1894.

The figures on which the results are based are given in Table A on next page.

The output from the station during this period had been at the rate of 1,797,120 Board of Trade units per annum, which represented a load factor of 28·5 per cent. It must be noticed that the costs, severally 0·5893d. and 0·6429d. per B.T.U.,

* For a full description of the method of making these tests, reference should be made to the *Proceedings* of the North of England Institute of Mining and Mechanical Engineers, December 8, 1894.

were for power delivered at the main switchboard. The average loss of power in the cables is not more than 3 per cent., and the motors have an average efficiency of not less than 90 per cent., so that the net cost per brake horse-power at the motor shaft may be taken with considerable accuracy at 0·515d. per hour during this six months. The items upon which these figures are based are as follows:—

	Per Board of Trade unit.	
	Willans.	Belliss.
	d.	d.
Coal (including cost of delivery and removal of ash), 17s. 5d. per ton. Willans, 3·41lb.; Belliss, 3·95lb. per Board of Trade unit	0·3180	0·3680
Water (7½d. per 1,000 gallons)	0·0228	0·0264
Stores, oil, waste, boiler-fluid, &c. (taken from last six months' consumption)	0·0416	0·0416
Wages, stokers, trimmers, drivers, labourers, electrical assistant (half-time), and switch-board boy	0·0977	0·0977
Steam for auxiliary pumps, feed (only 0·7 taken), air and circulating, water 0·003d., coal 0·026d.	0·0290	0·0290
Repairs to central-station plant and motors	0·0802	0·0802
Total cost per Board of Trade unit	0·5893	0·6429

Messrs. Siemens have had the capital cost of the old isolated steam engine plant taken out and compared with that for the central station electric plant, and find that the capital outlay per brake horse-power was 30 per cent. higher in the first case than in the second.

Summarising the tests, it seems to be abundantly proved that power distributed from an electric central power station costs less than when derived from independent steam engines; but whether it will pay to convert an existing plant from the old to the new system depends upon local circumstances, and the question can only be determined after carefully weighing all the factors of each problem on their merits.

Electrical Engineering in Russia.—Large new iron and steel works are being established at Ekaterinoslav in the Donetz district of Russia by a recently-formed Russo-Belgian Company—the Société des Forges et Aciéries d'Ekaterinoslav. The new works will be interesting, as not only will they be lighted throughout by electricity, but it is also intended to operate the whole of the machinery electrically.

MUNICIPAL TELEPHONY.*

BY A. R. BENNETT.

In this country we have had no actual experience of municipal control of telephone systems, although Glasgow and several of the other Scottish towns are desirous of making a move in that direction; but abroad things have been different, especially in Norway, where, in one town of importance, the telephone system has been owned and managed for the last six years exclusively by the Town Council; while in Christiania the municipality has contributed largely to the capital of the local telephone company, and, being represented on its Board by three town councillors, exerts a powerful influence on its management. These experiments have been so decisively successful that municipalities in other countries are taking steps to imitate them. Thus we find that the Town Council of Rotterdam is actually engaged in the construction of a telephone system of its own. The Rotterdam Municipal Exchange is to be opened in October, 1896; it is to be metallic circuit throughout, and the annual subscription is to be £6. 3s. 5d. for distances of five kilometres. The Town Council of Amsterdam has also resolved to build a new exchange, but neither the date of opening nor the subscription has yet been fixed.

The author then proceeds to discuss the present position of telephony in the United Kingdom. After depicting the monopoly conferred upon the National Telephone Company, first by its ownership of the master telephone patents, and then by the refusal of the Post Office to grant further licences, the author deduces as a consequence that telephonic charges in the United Kingdom are greatly in excess of those which prevail in most other countries, and approximate to double the figure at which they would stand if the earning of a fair dividend on the amount of capital invested in the construction of the exchanges were the accepted principle of the Company's action.

Unfortunately, even by the admission of the Company itself, its capital consists to a large extent of "water" on which dividends have to be paid; consequently, the charges levied on the subscribers must be higher than would be the case if companies or other bodies unhampered by surplus capital were permitted to take a share in the supply of British exchange telephones. Before the late Select Committee the National Company admitted that its capital was watered to the extent of £1,292,000. This amount, in the opinion of some who have studied the subject, should be at least doubled; but, accepting the Company's own figures for the nonce, and likewise the statement that the Company's lines numbered 73,338, it appears that £17. 11s. of "water" exists for each line owned by the National Company. Well, the late Dundee and District Telephone Company's lines cost £15 each; the late Mutual Telephone Company's (double lines), £16. 16s. each; the Christiania Telephone Company's, £12 each; the Trondhjem Municipality's,

* Abstract of a Paper read before the Northern Society of Electrical Engineers, November 11th.

Digitized by Google

£10. 2s. 6d. each. It is plain, therefore, on the National Company's own showing, that the "water" which exists for each line erected by the Company *exceeds the proper cost of the line*, and that each line must stand in the Company's books at much more than twice its actual cost. Such a state of things cannot exist without inflicting grave injury on the telephone subscriber as an individual, and on the commercial interests of the country as a whole, yet it is a state of things that the Government, through its Postmaster-General, did its best to justify, support, and perpetuate.

Unquestionably, to whatever cause the fact may be ascribed, the development of telephony in the United Kingdom has lagged behind that attained in many other countries. In Germany, Belgium, Norway, Sweden, Denmark, and other countries we find a large proportion of the towns connected by trunk lines, so that the subscribers may call up their correspondents in all parts of the country. In many cases the trunk lines have now passed the boundaries of the different countries, and the merchants of several of the capitals and of the chief ports and centres of industry in different countries may communicate telephonically. I am, of course, aware that trunk lines exist in this country and that communication has been established between London and Paris; but there is this important difference. On the Continent the charges made for the use of the trunk lines are extremely reasonable: thus in Germany, one can telephone all over the country for the sum of 1s. per three minutes; and even lower rates prevail in other countries. In the United Kingdom the charges are so heavy (and after January 1st next, when the Post Office will assume control of the trunk lines now worked by the National Telephone Company, they will be still further, in many cases, increased) that trunk-line communication remains a luxury. No doubt the Post Office could point to a considerable telephonic traffic between London and Paris, and perhaps between London and Manchester, Liverpool and Glasgow. But an analysis of this traffic will show that the lines are not used as a rule by the commercial or manufacturing communities, but by stockbrokers for the purpose of buying and selling stocks. Communication between London and Paris is almost exclusively to this end, and, I believe, the same applies to the use which is made of the new trunk line between London and Glasgow.

It may be remembered that the late Postmaster-General stated in the House of Commons that telephones in this country must always remain a facility to be enjoyed by the rich, and that even if by low rates a very large circle of subscribers could be obtained, the technical and engineering obstacles in the way of connecting them to an effective exchange were insuperable. Of course no practical telephone man believes that, even in this country; and abroad the statement of Mr. Arnold Morley has created much amusement, for foreigners have in their own cities, and even in their own villages, proofs before their eyes that the statement is inaccurate.

I recently made a minute inspection of the telephone system of Trondhjem, which is the third town of Norway, and possesses about 30,000 inhabitants.

The original telephone exchange was commenced in 1882 by a Mr. L. Spörck, who had obtained a concession from the Town Council. Mr. Spörck secured a considerable number of subscribers. But the service given was not entirely satisfactory, and in 1889 the Town Council determined to purchase Mr. Spörck's system, and thereafter manage the telephone business itself. Mr. Spörck having been paid the sum of £1,833 for all his rights, the Town Council proceeded to reconstruct his system in the most substantial and modern manner. The capital expenditure, including the aforesaid purchase-money, now stands at £7,979, with which sum 780 exchange and eight private lines have been constructed. The total number of lines being thus 788, it follows that each line has cost the town on an average £10. 2s. 6d. The population of the town being 30,000, there is one exchange telephone to each 38 inhabitants. In the United Kingdom the proportion is one in 636.

The rates fixed by the Town Council are as follows:—

	Per annum.
For a telephone exchange line connecting a place of business not exceeding 1½ kilometres (about 1 mile) from the central station	£3 6 7½
For a second business connection for the same person or firm...	2 13 3
For a private house, not exceeding 1½ kilometres from the central station	1 13 4

Should lines exceed in length 1½ kilometres these charges are increased by 5s. 6d. per annum for each 100 metres in excess. These charges include all payments. The Town Council supplies all the lines and instruments and maintains them. It is necessary to take particular note of this fact, because in some places in Norway and other countries subscribers buy their own instruments and pay the cost of their lines, circumstances which have sometimes been put forward as applying universally to all cheap Continental rates, but they are the exception, not the rule. At the middle of last October the value of the subscriptions on the books averaged £2. 14s. 4d. per telephone per annum.

The telephone business is managed by a telephone committee composed of two aldermen, one member of the committee being always a practical engineer. The committeemen retain their position for four years, and are thus able to obtain a thorough grasp of the business. Acting under the committee is a manager and engineer who has qualified in the latter capacity in the Trondhjem Technical School, and acquired considerable telephonic experience in other Norwegian towns. The capital is provided out of the rates, but interest at the rate of 4½ per cent. per annum is charged against the telephone system, so that the ratepayers not only lose nothing by the concern but even make a good profit. It should here be mentioned that the tariff given above is subject to alteration by the Town Council if such a course should appear desirable, so that the income may be adjusted to the expenditure, and any increase of cost in working thrown upon the telephone subscribers and not upon the ratepayers. It is, however, satisfactory to note that the tariff has sufficed hitherto not only to cover the working expenses, to provide interest on the capital, to create a reserve fund of 5 per cent. per annum on the capital expended, to insure all the employés against death, accident, and sickness, but to leave a small surplus every year.

The author then goes into the accounts of the Trondhjem municipal exchange at some length. In 1894 the estimated receipts were 34,900kr., the actual receipts were 35,507kr., or an excess of actual over estimated revenue of 607kr. The actual expenditure, on the other hand (including interest on capital, depreciation, and insurance premiums), only exceeded the estimated expenditure by 10kr., the figure being 34,310kr. In the 1895 Budget a profit of 2,700kr., or £150, was anticipated [1 krone = 1s. 1¼d.; 18 krones = £1].

Having told you the terms on which the telephone is supplied in Trondhjem, I shall now proceed to let you know what the subscribers obtain for their money. The subscribers are connected to the exchange chiefly by single aerial wires of phosphor-bronze, but some have copper wire carried in suspended cables. Communication is obtainable at present only between the hours of 8 a.m. and 10 p.m., Sundays included, but the early establishment of an all-night service is contemplated. There are 11 towns in the neighbourhood of Trondhjem where exchanges exist and with which trunk lines afford communication. These outlying exchanges are owned by local companies, not by the Trondhjem Municipality. The charge for speaking to them is 2d. for 5min. for subscribers, and 3½d. for non-subscribers. It is possible to speak for 5min. over a trunk line 47½ miles long for 2d. The Norwegian Post Office is also constructing, for the use of the Trondhjem subscribers, and has nearly finished, two metallic-circuit trunk lines to the North. These lines are of 3mm. silicum bronze. A trunk line to Christiania (349¼ miles) is also to be commenced in 1896. There is not at present any communication between the telephone system and the telegraph office, so that the subscribers are not able to forward telegrams from their own houses, but this defect is also to be remedied very shortly, the Town Council having promised to connect with the telegraph office whenever the Government desire it.

Subscriptions are payable half-yearly in advance. The subscriber is only required to sign an agreement for six months, and can discontinue his line at any time by giving notice of that duration. When the subscriber shifts his office or his house the cost of the labour of reconnecting him at the new place is charged, but the necessary material is provided free.

It has sometimes been said in extenuation of the high charges in force in this country that the low rates on the Continent are possible because the construction work is badly done; that cheap material is used, and no efficient technical supervision provided. I have already had occasion to emphatically disagee with these assertions, as in my book on "The Telephone System of the Continent of Europe" I give several instances in which the cheapest rates coincide with the best workmanship and most modern material and apparatus. Trondhjem is another case of this nature. The rates are very low, as we have seen, and yet the workmanship and material is extremely good. The wire used is of phosphor-bronze, 1·25mm. in diameter, being the same as generally used by the National Telephone Company in this country. Not only is the wire of the same nature and of the same gauge, but it is procured from the same makers, Messrs. Felten and Guilleaume, of Mülheim-on-the-Rhine. As Trondhjem is about 830 miles north of London, it follows that the freight incurred on the wire is very considerably in excess of that paid in England, so that the low rates in Trondhjem are certainly not attributable to the excessive cheapness of the wire used. This wire is supported principally upon iron structures, most of which are fixed on the house-tops, although some, as will be seen from the figures, are planted in the ground.

Fig. 1 shows the roof of the Trondhjem Telephone Exchange, with the six iron structures provided to receive the subscribers' lines. In Fig. 2 we have a roof fixture, from which the members of this society will deduce that telephone house-fixtures are not necessarily ugly. This fixture is on the Trondhjem Museum. Fig. 3 shows a pole line along the Nordre Gade.

These photographs will show that the Trondhjem telephone fixtures are of a substantial nature. They are, in fact, made of

Digitized by Google

English angle iron, 2in. in the web by ¼in. thick. The cost of the iron alone, unpainted, in the larger ones is about £15. The preparation of the roof for fixing, and the labour, increases this cost materially. As English iron is employed, on which freight has to be paid to Trondhjem, these overhouse fixtures cannot be cheaper than those employed in this country.

The subscribers are supplied with the beautiful instruments manufactured by the Norske Elektrisk Bureau of Christiania.

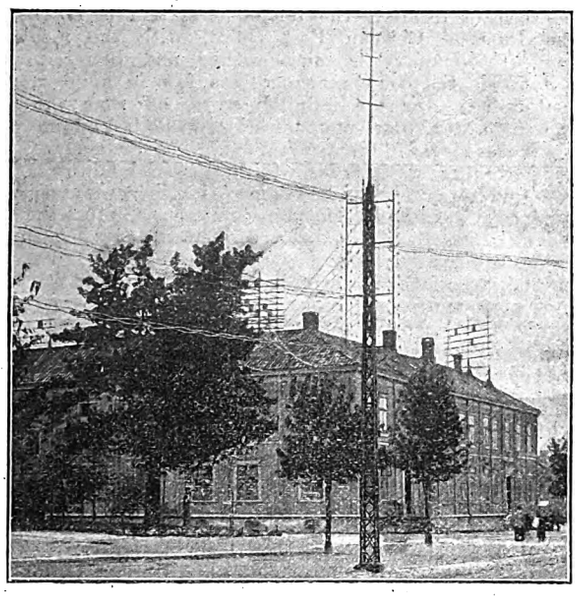

FIG. 1.—Trondhjem.—Iron Lattice Pole, with view of Central Exchange.

These cost £2. 12s. 2d. each, delivered free in Trondhjem, in lots of not less than 100, exclusive of battery. Such subscribers who desire it are supplied with instruments made by Messrs. L. M. Ericsson and Co., of Stockholm, the price of which is higher, viz, £2. 17s. 8d., in lots of 100, delivered in Trondhjem. The Trondhjem instruments, therefore, cost more than those supplied to telephone subscribers in this country, while their workmanship is superior.

The insulators used for supporting the wires are made at Porsgrund in Norway, and cost 2d. each without the bolt. They are of

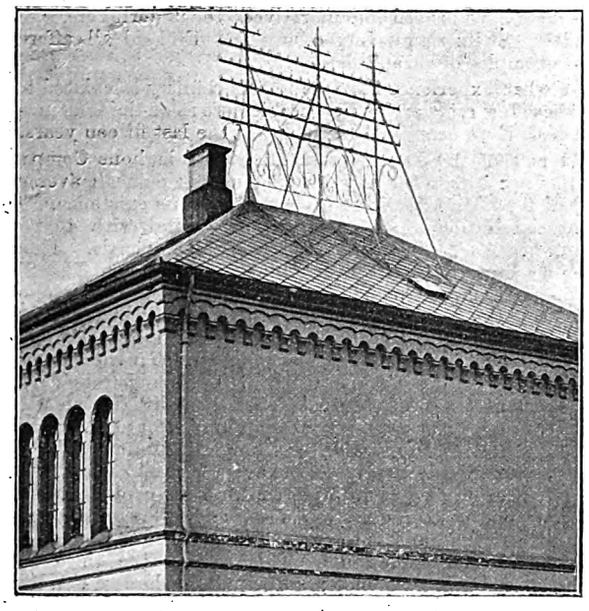

FIG. 2.—Trondhjem.—106-Wire Standard on the Museum.

a double-shed pattern. On some of the more crowded routes the subscribers' wires are led in suspended cables. Two of these cables contain 50 wires each, and are of the Pattinson type, that is to say, the wires are insulated with desiccated cotton saturated in paraffin wax, and protected by a heavy leaden tube. Others contain 25 wires and are insulated with india-rubber protected by lead in the sanie way. These last cables were supplied by Felten and Guilleaume

The working staff consists of five linemen, who work from 7 a.m. till 6 p.m., with one hour off for dinner. Their pay is £43. 6s. 8d. per annum, with an extra allowance of £6. 13s. 3d. to the oldest man, who acts as foreman. The Town Council insures each man for £111 against death, and also for allowances in case of accident or sickness, the premium paid being 9s. 11½d. for each £55 of wages. Although the pay of these men may appear low, it is extremely doubtful whether that of the telephone linemen in any town of equal size, 30,000 inhabitants, in the United Kingdom averages so much. The operating staff consists of young ladies, eight of whom, with the superintendent, are on duty at one time. At present their duties average a little less than 9½ hours per week day, but as this is considered too long three new operators are about to be appointed. Their pay at present varies from £2. 4s. 5d. to £2. 15s. 5½d. per month, but the scale of wages sanctioned by the Town Council provides for an ultimate increase to £3. 6s. 7½d. per month. The pay of the lady superintendent is at present £40 per annum. In addition, there is a staff of reserve operators, consisting of young girls who have learnt the business, but who, pending vacancies on the permanent staff, are only called in on emergencies. They receive a small retaining fee and are paid for work actually done at the rate of £2. 4s. 5d. per month. As each subscriber asks on the average from eight to nine connections per day, the girls have plenty to do during the busy hours. Each girl has 14 days' holiday per annum on full pay, and is insured against sickness. It will be seen that whatever may be thought of the workmen's wages, the lady operators receive considerably more than their English sisters. It is certainly a strange comment on

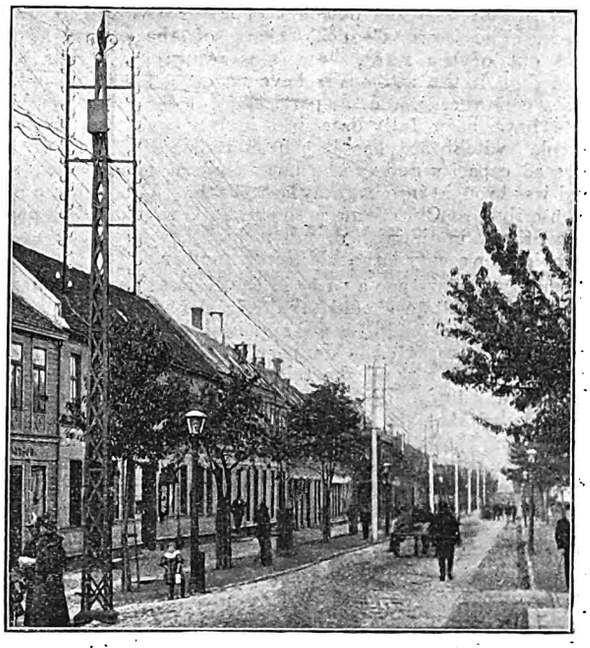

FIG. 3.—Trondhjem.—Route along the Nordre Gade.

the talk we have heard of the greater cost of telephonic work in this country to find that girl operators in Trondhjem are paid better than those of London, Manchester, or Glasgow.

In estimating the cost of working the Trondhjem exchange it is necessary to explain that the Town Council have no wayleave charges to bear. They use the townsmen's roofs by agreement, but in every case at present the proprietor is content with his roof being kept in repair, and exacts no annual payment. Of course it is a serious matter to keep so many roofs in good order, but certainly the Trondhjem Town Council is exceptionally fortunate in escaping money payments in addition.

In another respect the Trondhjem municipality is more fortunate than telephone undertakers in this country; the 10 per cent. royalty payable to Government on exchange telephone subscriptions has no existence in Norway. Not that 10 per cent. added to the Trondhjem tariff would make much difference. The average payment would then be £2. 19s. 9d. instead of £2. 14s. 4d. Even a 10 per cent. royalty only assumes alarming dimensions when the subscriptions on which it is levied are high.

The switching arrangements at Trondhjem at present consist of eight 100-line boards, by Ericsson and Co., Stockholm. There are no special features about them. The ring-off drops are connected in the cords in the usual way. This arrangement is somewhat antiquated, and will next year be superseded by a multiple board. A cross-connecting and lightning-guard board is also provided, the lightning guards being of carbon blocks lying on a

Digitized by Google

carbon plate in connection with the earth, and kept from contact with it by strips of mica. All the work in the exchange has been carried out with excessive neatness, and there is no suggestion of cheapness or neglect about the place.

The second instance of municipal control of telephone systems in Norway is that of Christiania. In my work on "The Telephone Systems of the Continent of Europe" I give full particulars of the Christiania Telephone Company, which has been a most successful concern. On an inclusive subscription of £4. 8s. 11d. it has for many years past paid a dividend of 5½ per cent. per annum on the capital invested, after putting aside large reserve funds, writing off values of buildings and system, and providing benevolent funds for its male and female employés. The accounts given in my book for the years 1893 and 1894 bring out these details very clearly. At the end of 1894 the Company possessed 4,627 exchange lines in Christiania and it simmediate suburbs, in addition to being owner of a large system of trunk lines connecting Christiania with the neighbouring towns in every direction. At the end of September, 1895, the number of exchange lines had increased to over 5,000. The management of the Company is invested in four directors, who meet every week, and a managing council consisting of fourteen shareholders, which meets every month. This council is elected by the general body of shareholders, and in its turn elects the four directors. The Town Council, which owns a proportion of the shares, is represented directly on the board of the Company by three town councillors, one of whom is a director, and the other two members of the managing council. The municipality consequently exerts a great influence on the Company's policy, which is to provide the best possible communication at the lowest rates commensurate with the payment of a fair dividend to the shareholders. The Town Council's share of the capital is contributed out of the rates, but as a return of 5½ per cent. is obtained on it the ratepayers have no cause for discontent. The outside construction and the particulars of the subscribers' instruments have been fully described in my book, but the original multiple switchboard has just been replaced by one of largely increased capacity and of the most modern type, which switchboard was brought into use only last month. Although the number of subscribers at Christiania is so great the rate at which new ones join continues undiminished, and it has therefore been necessary to provide for a very large additional number.

About two years ago a party in the Norwegian Parliament suggested that the State should take over the whole of the telephone companies, and a committee was appointed to examine the proposal. The committee reported in January, 1894, by a majority in favour of the State acquiring all the telephone exchanges as well as the existing trunk lines. But there was also a minority report which recommended that the State should only acquire the long trunk lines, leaving the local exchanges and the shorter trunk lines in the hands of the private companies and municipalities already working them. When the report of the committee was published, the Norwegian telephone companies and municipalities owning telephone systems formed themselves into a Defence Association. The Defence Association adopted the minority report. For two sessions no action was taken on the report of the Committee, the number of the advocates of State acquisition being estimated at only about 20 per cent. of the members of Parliament; but just before the conclusion of the last session, in July, 1895, the permanent Parliamentary Committee, which controls the posts, telegraphs and railways, recommended that the Government should adopt the minority report of the original Committee, and thereupon the Ministry decided that the Government should acquire the longer trunk lines only, leaving the local exchanges and shorter trunk lines, as they are at present, in the hands of municipalities and private companies. Private or municipal enterprise has, therefore, been definitely left in Norway to deal with the telephonic question, and from the energy and technical skill which the Norwegian telephone engineers have exhibited in the past there can be no doubt of the result; and it may be assumed that Norway will continue to develop her telephonic system to an extent of which most people in this country have no sort of conception.

There can be little doubt that State telegraph departments are not the best managers of telephonic facilities. In my Paper read before the British Association at their recent Ipswich meeting I gave many statistics and particulars on the progress of telephony in the chief European countries, from which it appeared that the greatest development and the lowest rates, together with the most liberal concessions to the public, are coincident not with Government control but with private enterprise. This view of the case has, since the meeting at Ipswich, been confirmed independently in a very singular manner.

Jutland is covered by telephone exchanges, there being scarcely a village not possessing one, while trunk lines connect all these together, and cover the country with a very network of wires. In Schleswig-Holstein there are scarcely more than half-a-dozen telephone exchanges. The Chamber of Commerce of Flensburg, one of the chief towns of Schleswig-Holstein, has recently forwarded copies of maps to the Imperial Government in Berlin pointing out to the Government what I am now pointing out to you, that in Jutland, where telephonic enterprise is entirely in the hands of private companies, the country is covered with telephonic exchanges and telephonic trunk lines; that subscribers there are never charged more than £4. 3s. 4d. per annum, while in the majority of cases the charges do not exceed from £2. 10s. to £3. 10s. per annum. But in Schleswig-Holstein, south of the Danish frontier, the telephone system is in the hands of the Imperial German Post Office, with the result that, although the country is much richer and better populated than Jutland, telephone exchanges are few in number, possess few subscribers, and are infinitely worse off than the Danish in respect to trunk-line communication, while the annual charges are never less than £7. 10s. per annum. The Flensburg Chamber of Commerce present these facts to the Imperial Government and petition that measures may be taken to improve the development of telephones in Schleswig-Holstein, and especially that the present excessive charges should be reduced, pointing out that the social conditions of Schleswig-Holstein are practically the same as those of Jutland, and if the rates of between £2. 10s. and £3. 10s. are remunerative in Jutland, they should be made equally so in Schleswig-Holstein. With the petition was forwarded a list of some of the Danish companies giving particulars of their capital, number of subscribers, and dividends, from which it appears that the last range from 5 per cent. to 16 per cent. A more apposite and striking example of the differences between the management of Government departments and the results which follow the application of local intelligence, skill, and the employment of local capital, it would scarcely be possible to find, for only a few years ago Schleswig-Holstein belonged to the kingdom of Denmark, and was politically what it still is geographically, a part of the peninsula of Jutland. Had it remained Danish, Schleswig-Holstein would doubtless be to-day as well telephoned as Jutland is, for private enterprise would not then have been killed by Government monopoly.

The German Telegraph Department is a highly organised concern, but it suffers from over-centralisation. The headquarters are in Berlin, and nothing can be done, however trivial, in any town or village in Schleswig-Holstein, or any other part of the vast territory controlled by the Department, without previous consultation with, and permission obtained from, Berlin. Local conditions are ignored, and the smaller towns and villages can only obtain telephonic facilities by guaranteeing the Post Office, over whose management they have no control, against loss.

It must not be supposed that low rates are peculiar to Norway. Of the 31 exchanges in Holland, all but three enjoy rates ranging from £4. 19s. 1½d. per annum down to £2. 9s. 7d. per annum, and these rates have proved remunerative to the undertakers. Sweden, Denmark, Switzerland, Luxemburg and Finland all afford additional examples of cheap telephony.

But what experience have we in this country calculated to show that these low rates are as practicable here as on the Continent? A good deal, if we examine the history of the last fifteen years.

The rate of the Dundee and District Telephone Company was £5. 10s. per annum for any distance, and it paid an average dividend of 9 per cent. during the 4¼ years of its existence. To buy it out the National had to return its capital with 40 per cent. added, besides paying bonuses to the chief officials. The cost of the lines erected by the Company was £15 each. The Sheffield Telephone Company paid good dividends for many years on a £7 rate. But the best and most recent example occurred in your own city of Manchester, where the Mutual Telephone Company constructed an exchange in 1891, at rates which varied from £5 for shareholders in the Company to £6 for non-shareholders. The cost of connecting the Mutual subscribers by double wires was £16. 16s. each; the average subscription, after deducting 10 per cent. for Post Office royalty, was only £4. 12s. per line, a figure which approximates closely to the average receipts in Christiania; and yet, after putting aside 5 per cent. on the capital expended for deterioration, paying directors' fees, and all working expenses, sufficient surplus was left to pay a dividend, had it been so desired, of 2·29 per cent. per annum. This was in the third half-year of the exchange's existence; subsequently the revenue increased rapidly, and with it the profit. At one time the Mutual Company had 1,389 lines working, but such a formidable rival could not be tolerated.

There is only one other aspect of the situation to which I will call attention before concluding; it is the woeful effect which the existing monopoly is having upon our electrical industry. Abroad, immense quantities of telephonic apparatus are required to meet the rush of subscribers, and everywhere—in France, Germany, Belgium, Switzerland, Sweden, Norway—we find extensive factories already in existence which are devoted entirely to the production of telephonic switchboards and apparatus, and more are continually coming into being. We have nothing of the kind in this country.

Digitized by Google

Why? Because all important orders for instruments and switching apparatus are, and always have been, placed abroad, principally in America, and, as a consequence, no development of a British telephonic instrument industry has been possible.

PHYSICAL SOCIETY.

At the ordinary meeting of this Society on November 8th, Prof. A. W. Rücker (Vice-President) in the chair, Mr. W. H. EVERETT read a Paper

"On the Magnetic Field of any Cylindrical Coil or Plane Circuit."

The method of treatment is based on the formula for the force due to an element of current. A single integration applied to one component of this force gives for any point in the field due to a plane circuit the force perpendicular to its plane, and a double integration gives the longitudinal force at any point due to a cylindrical coil of any cross-section, the depth of winding being supposed inconsiderable. For coils in which the latter condition does not hold, an approximate solution can readily be found. The force parallel to the plane of a circuit and the transverse force due to a coil are investigated in a similar manner. The general results are of a very simple form, and admit of easy approximate calculation. Special formulæ are deduced for coils of rectangular cross-section, the general expressions being in this case integrable. Appended to the Paper are some numerical results giving the values of the forces at different points, due to coils of various dimensions.

Prof. PERRY said he considered the Paper to be a valuable one, particularly as illustrating a practical mathematical method of integrating.

Mr. TROTTER said the Paper was of interest to him, as he considered that several of the author's results might be applied to the solution of problems on illumination—for example, of the illumination of a room by a circle of lamps.

Mr. RHODES regretted that it had not been possible to supply a proof of the Paper before the meeting. The method in which the author obtained the force outside a solenoid, as the difference of the forces due to two solenoids, reminded him of the method employed in calculating the attraction of, say, a truncated pyramid.

Prof. SILVANUS THOMPSON said the author had mentioned several previous Papers on the subject, but had not referred to one by Prof. Viriamu Jones, in which the force due to a solenoid is obtained in terms of elliptic integrals. Another method of attack was to calculate the work done when a unit pole is carried through the solenoid and back outside to the starting point.

Prof. AYRTON said he also regretted the absence of a proof of the Paper. He considered it of great importance to have exact and simple methods of calculating the forces due to a solenoid.

The CHAIRMAN (Prof. Rücker) said he had made a somewhat similar calculation in connection with the magnetic effect of sheets of basalt below the surface of the earth.

GAS ENGINE STATIONS FOR TRUNK LINE RAILWAYS.*

While on their annual tour of inspection last month the directors of the Pennsylvania Railroad were taken to the works of the Westinghouse Company, at Brinton, near Pittsburgh, and shown the latest advances in electric railway apparatus. At that place they were addressed by Mr. Westinghouse, who had on request prepared special data upon the operation of railways electrically by power stations employing gas engines. In the course of his remarks Mr. Westinghouse said:

"A strong argument heretofore used against the adoption of the electric system for main lines has been due to the fact that the investment required to make the change would be heavy, without materially decreasing the consumption of fuel and other costs of operation, an objection which it is believed can be met by the development and use of gas engines of large sizes instead of steam engines, for the generation of the electric current."

After presenting arguments to show that the gas engine would use but one-eighth the fuel of an ordinary locomotive to produce similar power, Mr. Westinghouse continued:

"The Pennsylvania railroad to-day, it is said, consumes about 5,000,000 tons of coal per annum on its lines east of Pittsburgh, taking, approximately, 20 loaded trains each day for its transportation, and consequently the return of 20 empty trains, and requiring for the service of the Company alone fully 3,000 cars and a proportionate number of locomotives. If this power were to be generated by gas engines, only about one-eighth, or 600,000 tons of coal per year would be required, effecting a saving of over 4,000,000 tons of coal, now costing the railway company above $5,000,000, a saving which would justify a large enough capital expenditure to cover the complete equipment of the railway. To carry out an arrangement of this character, stations having electric generating plants with gas engines and producers, could be located at intervals of from 10 to 12 miles, so that there would always be two or three stations furnishing current for any particular part of the line. The electric locomotive for hauling such trains would be entirely different from the present locomotive, and could obviously permit of changes in operation, for no electric locomotive need have a greater weight and capacity than needed to haul from 25 to 30 cars. It can be operated by one man and will be of such a shape that it can be conveniently used as a caboose car and for the carrying of tools and appliances for cases of emergency. Instead of putting the whole motive force in front, and thereby subjecting the road-bed, bridges and cars to excessive weights and strains, a second locomotive can be conveniently placed in the centre of long trains, thus subdividing the force applied for its propulsion, thereby reducing to convenient limits the quantity of current required for the operation of a train, though, as has already been demonstrated, electrical locomotives can be made which will have greater hauling capacity than any steam locomotive which has yet been produced. The electric operation of railways permits readily of a more frequent and rapid train service than is possible with steam locomotives, and it is not impracticable to attain, upon properly constructed and guarded tracks, very high speed, so that a very frequent service of very light trains between such cities as New York and Philadelphia, Baltimore and Washington could easily be provided, to the great advantage of the public and to the profit of the company undertaking such a plan of operation."

* From the *Electrical Engineer* of New York.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

TUESDAY, November 19th.

BOARD OF TRADE.

11 a.m. Conference at the Westminster Town Hall, between the Board of Trade and the objectors to the proposed revised electric light regulations.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be read: "The City and South London Railway: Subaqueous Tunnelling by Shield and Compressed Air," by James H. Greathead.

WEDNESDAY, Novmeber 20th.

ROYAL METEOROLOGICAL SOCIETY.

7:30 p.m. Ordinary Meeting at the Institution of Civil Engineers, 25, Great George-street, Westminster.

SOCIETY OF ARTS.

8 p.m. First Ordinary Meeting. Opening Address of the 142nd Session, by Major-General Sir John Donnelly.

ROYAL MICROSCOPICAL SOCIETY.

8 p.m. Meeting at 20, Hanover-square, W.

FRIDAY, November 22nd.

PHYSICAL SOCIETY.

5 p.m. Meeting at Burlington House. (1) "An Exhibition of Photographs of Spectra," by Dr. G. Johnstone Stoney. (2) "A Direct Reading Platinum Thermometer," by R. Appleyard. (3) "Historical Note on Resistance and its Change with Temperature," by R. Appleyard.

*** Particulars of Meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

Society of Arts.—The following are some of the arrangements for the ensuing Session:—The first meeting will be held on Wednesday evening, November 20th, when the opening address will be delivered by Major-General Sir John Donnelly, K.C.B. Previous to Christmas there will be four ordinary meetings, in addition to the opening meeting. On November 27th there will be a Paper on "Locomotive Carriages for Common Roads," by H. H. Cunyughame. After Christmas there will be Papers on "The Making of a Great University for London," by Prof. Silvanus Thompson, and on "Standards of Light," by W. J. Dibden. The following are some of the courses of Cantor lectures arranged for Monday evenings at eight o'clock: W. Worby Beaumont, M.Inst.C.E., "Mechanical Road Carriages," three lectures, December 2nd, 9th, 16th. Dr. J. A. Fleming, F.R.S., "Alternate Current Transformers," four lectures, January 20th, 27th, February 3rd, 10th. James Swinburne, "Applied Electro-Chemistry," four lectures, April 27th, May 4th, 11th, 18th.

The Electrician.

The Oldest Electrical Journal (1861—1878.)

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny.
Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 6949. *Telegrams:* "ELECTRICIAN NEWSPAPER LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The Rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	Year.	Half-Year.	Quarter.
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.

(Post free, payable in advance.)

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to* 4 *p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. *Vol. II. is in preparation.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free, 8s.
VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. 93 original illustrations, handsomely bound, price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. SNELL. 10s. 6d.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free 8s.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

"THE ELECTRICIAN" PRIMERS. In Two Volumes. Price: Stout paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

THE WORK OF HERTZ. By Dr. O. J. LODGE. Price 2s. 6d.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 2s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. *[In preparation.*

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. *[In preparation.*

NOW READY.—Vol. XXXV. of "THE ELECTRICIAN," bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

The published price of Volumes previous to Vol. XXXV. is 12s. 6d., post free 13s. 6d. Many of these Volumes are very scarce.

AMERICAN STREET RAILWAY FINANCE.

Americans are prone to statistics, which they mostly hurl at us "in the loomp," ill-digested and ill-arranged, without any attempt at elucidation or philosophical generalisation. For a little *brochure* recently published by the Street Railway Publishing Company of New York there can, however, be nothing but commendation. Into a little over one hundred well-printed pages Mr. EDWARD E. HIGGINS has succeeded in compressing a mass of statistical material relating to "Street Railway Investments" in a way which renders it well-nigh attractive and undoubtedly renders it instructive.

Before Mr. HIGGINS' figures and deductions can be strictly applied to this country, a coefficient should, perhaps, be applied to them. It is possible, however, that its non-application would not give rise to so grave an error, as might at first be thought probable. In changing over from horse to electric traction in England there would not in all probability be the undue inflation of capital resulting from the elegant financial process known as "watering," from gross extravagance in the matter of extensions and electrical equipment, and from the high cost and crude nature of the electrical equipment; causes which have been fruitful of grave overcapitalisation in America. On the other hand, with us the work would have to be far more solid, and the traffic, we are afraid, would not respond to the increased facilities offered to the same degree that it has in the United States. "The municipal transportation industry in the United States is intrinsically profitable;" says Mr. HIGGINS; it is not so here, at any rate so far as tramways are concerned. With us there has been up to the present no "national passion for rapid transit" such as exists in America. "The average American is careless of small economies. He has no time to 'split a nickel'; he despises a penny"; not so the average Englishman. Hence, while we are inclined to think that the net result to the

Digitized by Google

tramway investor in changing over from horse to electric traction in this country will be better than that which has obtained in America, it will not be markedly so. We may not so wantonly and extravagantly over-capitalise, but we shall not witness such an extraordinary, such a sudden, such a permanent upward bound in the traffic returns.

The world has probably seen nothing comparable to the sudden revolution in, and extension of, tramway traction which began in the United States in 1888, and in five years drove the horse nearly out of the business. Let us see by the light of Mr. HIGGINS' compilation how it has been done and how the revolution looks from the £ s. d. point of view. "It is safe to say," he remarks, "that the gross mortgage indebtedness of our street railways is to-day double what it was in 1888; that the capital stock has been increased in an even greater ratio, and that the gross capitalisation per mile of track is so far in excess of that of 1888 that the entire difference cannot be explained on the score of cost of reconstruction and change of motive power." This difference has mainly been caused by the purchase in the sanguine mood begotten of an electric traction "boom," of the old horse lines for far more than they were worth and their conversion at an extravagant price and in a crude and hasty manner into electric lines. Then there were too rapid extensions, and the gains of promoters. It is some satisfaction to learn that the bonds "have not yet found the ultimate investor," and are still held largely by bankers, brokers and syndicates.

The basis of the electric tramway "boom" in the United States was as follows. Cable and electric systems of motive power "were first introduced in the belief that the actual reduction in operating expenses would be sufficient to yield satisfactory returns on the additional investment required. This expectation has not been precisely realised. Total operating expenses have been somewhat greater than before, instead of less, because of the sudden and amazing increase in traffic. . . . But the operating expenses per car mile and per passenger carried, and the percentage of operating expenses to gross receipts, are, in general, sensibly reduced." And this "in spite of unexpectedly large repair accounts." Mr. HIGGINS' general conclusion is that American "street railways, as a whole, have been profitable even when operated by horses, and that the general adoption of electricity and the cable has invariably brought about a substantial increase in gross receipts and almost invariably an even greater proportional increase in net." As he quite rightly remarks, "the real question becomes, therefore, whether or not there has been serious over-capitalisation of the permanently safe net earnings." Some clue as to the proper answer to this important question and to another one—less important perhaps, but quite as interesting—is afforded by Mr. HIGGINS' statistics and comments relating to a batch of six electric railways serving, in 1892, "cities" of from 25,000 to 35,000 inhabitants, the six lines being in 1890 all run by horses.

It is decidedly interesting to learn exactly whence came all the money necessary for "power-houses," "car-barns," "welded-tracks," "radial-trucks," "vestibule-cars," and 25 H.P. "T.H.W.P. single-reduction" motors, not to mention trolley poles and wires, feeders and copper "earth-returns." On p. 28 of Mr. HIGGINS' excellent compilation we have it all in plain English. "In facing the problem of adopting electricity as a motive power the managers of horse railway properties, both in this and in other classes, soon learned that it was necessary to provide nearly enough money to entirely rebuild and re-equip their roads *de novo*. The actual selling value of their tangible assets shrank to insignificant proportions. Electric motors were too heavy for the old cars, and the latter had no selling value; the introduction of heavy electric cars made it necessary to reconstruct the road-bed and to sell the old rails at scrap prices; the old barns and car houses were usually sacrificed; and fortunate was the manager who could obtain for his horses even one-third of their original cost. Nevertheless, the old security holders had to be provided for, and, naturally enough, the new investment was added to the old, and the capital liabilities were made to represent what was really the cost of building duplicate roads plus the cost of extensions. If this had been all; if new securities could have been sold at par; if the prices for apparatus and construction work had been on an entirely cash basis; and if the promoters had not generally required large profits, the percentage returns on the new capitalisation, even with the duplication of investment account above described, would probably have been in nearly every case increased, particularly in the larger places. Unfortunately, however, there were many cases where these exceptionally favourable conditions did not obtain. The most common form of financing these enterprises was to issue mortgage bonds having a par value somewhat greater than the valuation placed upon the old properties, plus the estimated requirements for making extensions and equipping by electricity. Stock was then issued, frequently for about the same par value as the bonds, although the proportions varied according to the fancy of the promoters. The theory of the latter was that the sale of the bonds at a moderate discount would provide all the necessary money for the entire work, and that the net income would largely exceed the fixed charges, so that substantial dividends could be earned on the stock." Well, we are very desirous of seeing electric traction develop in this country, but not on these terms nor anything like them. Perhaps we in England have reason to be thankful that, owing to the municipal purchase clause, financial hocus-pocus of this order is out of the question, and that owing to the small mileage of our existing tramways the larger portion of our *in futuro* electric tramways will not be converted horse lines, but entirely new ones. But, even on American showing, the conversion of horse lines can be made to pay, if the change over be done with due care and caution, and by the light of the experience gratuitously accumulated for us by our good friends across the Atlantic. Let us examine the combined figures of the six systems just referred to. In 1890 the average capital liability per mile of track—not capital outlay, be it observed—was £2,780; in 1892 it was £8,740, or more than threefold. But the change from horse to electricity resulted in a great increase in net earnings. In 1890 the *total* net earnings of the six systems averaged £1,075, and in 1892 £3,246. The average mileage of the six systems had, however, increased nearly 50 per cent., so that the final outcome of the adoption of electric traction was that the percentage ratio of the net earnings to the total capital liabilities was in 1892 only 3·8 as against 5·2 in 1890.

Mr. HIGGINS' tables and statistics and comments, therefore, while they are in themselves exceedingly good, and while they throw invaluable and instructive side-lights on American electric tramway finance and its results up to date, need afford nothing but encouragement to investors and financiers at home. The particular case which we have investigated in some detail is not a favourable sample, even of American tramway management. Its moral is, it seems to us, that if you are content to change over from horse to electric traction in a reasonably careful, reasonably honest way, your net earnings per mile will increase at a greater rate than your capital expenditure per mile, provided you do not straightway add some 50 per cent. more miles to your system.

REVIEWS.

Elektrotechnisches Worterbuch. English-French-German. By J SACK and ARTHUR WILKE. (Leipzig: Oskar Leiner.)

There is a great need for a really reliable and fairly complete electrotechnical English-French-German dictionary. Electrical engineering is peculiarly international, and whilst few electrical engineers can be said to be conversant with French and German, most of them can by dint of heroic perseverance, frequent use of a dictionary, and unlimited guessing, make very tolerable sense out of even a German electrical article. The modest little dictionary before us bears evidence of considerable care in its compilation, and its authors have evidently followed the developments of electrotechnical language in England and America very closely. In the preface Herr Wilke, who took over the task on the death of Herr Sack, makes a plaintive appeal for forbearance on the part of those who seek and cannot find the particular word they want. He is inclined to lay the blame for any shortcomings in this respect upon us Anglo-Saxons, who are for ever word-coining, picking up handy expressive terms wherever we can find them, defying etymology, and puzzling poor Teutonic lexicographers. Herr Wilke's rule has been to omit all words which are printed in the technical journals in inverted commas; hence "booster" goes by the board. It does one good, however, to hear such adepts at the art, as Germans are, complaining of our *Wortbildungskraft*.

With a view to the improvement of the second edition and not in a spirit of captious criticism, we will point out one or two minor errors. Words such as "to condensate," "conductibility," do not strike us as exactly the best electrical English, although they are to be found in Webster. *Empfindlichkeit* would probably be better translated as "sensitiveness" than as "delicacy" or "sensibility." "Dissimulated electricity" for "bound electricity" is somewhat of a curio; as is also "far-leading dynamo" for "long-distance transmission dynamo." The intrinsic brilliancy of the, to us, new term "foot-candle" does appear very great.

Cours Élémentaires d'Électricité. By BERNARD BRUNHES. (Paris: Gauthier-Villars et Fils.)

This volume is a reprint of the course of lectures on theoretical electricity which is delivered by the author to the first-year civil engineering students of the Institut Industriel du Nord de la France. The subject is treated in an elementary manner, but lucidly and rigorously. The typography and illustrations are excellent. M. Brunhes' course of lectures should prove of considerable use to those who are desirous of acquiring a clear idea of the fundamental principles of electrical science.

Digest of British and Foreign Patent Laws. By ALFRED J. BOULT, M.I.Mech.E., Chartered Patent Agent. (London: Bemrose and Sons.)

This is a handy well-arranged little volume of some 400 pages, giving a very concise digest of the patent laws of Great Britain and other countries. English patent law is adequately summarised in 50 pages. As the author points out, it is inevitable that as years go on "the extent of patentable subject matter in any particular branch" should grow less, and however much patentees may dislike the whittling down of their epoch-making inventions, they will do well from a business point of view to restrict their claims within narrow limits on the well-know principle that half a loaf is better than none. Allusion is also made to the "waves of feeling" that sweep over the Bench; at one time claims are subjected to the severest scrutiny, at another time there is a mania for "benevolent" construction. To-day novelty is judged in some measure by commercial results; if the patented article is largely sold, the probability is that it will be held to have been patentable. The author is evidently somewhat sore at the Quixotic generosity with which England carries out the provisions of the International Convention. We certainly lose by the comparative savagery of foreign countries in the matter of the treatment they mete out to English inventors, but we should lose still more by reprisals. Those responsible would, however, do well to see to it that whenever any of the offending countries are anxious for some political or commercial concession from this country, the bringing of their patent laws into conformity with the spirit and letter of the International Convention is made a *sine qua non* of the concession. The complexities and perplexities which confront a patentee who wishes to obtain valid long-lasting foreign patents give a fund of meaning to that well-worn formula, "owing to considerations connected with foreign patents it would be unwise to supply the full particulars desired."

Étude sur le Transport de l'Energie à Grande Distance par l'Electricité, et sur les Transmissions Électriques par Courant Continu. By GEORGES DUMONT and GUSTAVE BAIGNÈRES. (Paris: A. Grélot.)

This is a reprint, with additions, of a Paper read by the authors in November, 1894, before the Société des Ingénieurs Civils. It is divided into three sections, dealing respectively with long-distance transmission, distribution for power purposes, and actual examples of electric plants. The subject is treated in a somewhat academic manner, but scattered up and down the hundred odd pages of the volume there are many useful data derived from actual tests.

Brush Arc Light System. By H. C. REAGAN, JR. (New York: N. W. Henley and Co.; London: E. and F. N. Spon.)

Mr. Reagan's little *brochure* is one of the best of the kind we have seen. It is intended, of course, for American readers, but its extremely clear explanation of the action of the Brush arc-light machine, and its equally clear diagrams, should render it of considerable educational value to dynamo men and assistant central station engineers wherever machines of the Brush type are used.

Electric Light for Country Houses. By JOHN HENRY KNIGHT. (London: Crosby, Lockwood and Son.)

This little book deals with the electric lighting of small country houses, not of ancestral halls. The way to set about a job of this kind is made plain and the probable cost of the work is given. To those contemplating lighting their houses by electricity and wishing to know "something about it" before entering into negociations with a firm of contractors, Mr. Knight's notes should prove of considerable use.

Leçons Elementaires de Télégraphie Électrique. By L. MICHAUT and M. GILLET. Second edition. Entirely recast. (Paris: Gauthier-Villars et Fils. 1895.)

This is intended as a manual for Morse operators, and should give them a clear insight into the scientific basis of land-line telegraphy.

THE CARBORUNDUM WORKS AT NIAGARA FALLS.

BY ORRIN E. DUNLAP.

Carborundum, the new abrasive, is now being turned out at a factory at Niagara Falls. Carborundum was discovered in 1891 by Mr. E. G. Acheson, President of the Carborundum Company. For several years Mr. Acheson had been on the look-out for some method of crystallising carbon, as he recognised that such a material would prove of great value as an abrasive. It was not, however, until the year 1890, when he became associated with an electric lighting company in Monongahela City, Pa., that he had an opportunity of carrying out experiments. In his first experiment he used an iron bowl lined with carbon and filled with a mixture of carbon and clay, into which a carbon rod was introduced. The bowl and carbon rod served as electrodes, by means of which a current sufficient to fuse the mixture was supplied, the object being to cause the carbon to be dissolved in the melted silicate of alumina, and, by cooling the same to the point of solidification, cause the contained carbon to crystallise. When the current was applied and the mixture heated up, a violent chemical reaction appeared to take place. When cooled down the mass was carefully examined, with the result that a few bright blue crystals were found. These crystals were carbide of silicon, or, as they are called commercially, carborundum. The latter name is made up from carbon and corundum, as it was supposed before a

Digitized by Google

chemical analysis was made that carborundum was a compound of carbon and alumina.

The manufacture of carborundum as now carried out at Niagara Falls is as follows:—The materials used are coke, sand (which is very rich in silicon), salt and sawdust, the two latter being used to facilitate the operation of the furnace. These are mixed in proper proportions and introduced into the furnaces (*see* Fig. 1), which are of brick built up into four walls so as to form a kind of rough brick box, no mortar or cement of any kind being employed. In the centre of each end wall of the furnace is a large bronze plate, to which are connected the cables carrying the current. When complete the internal

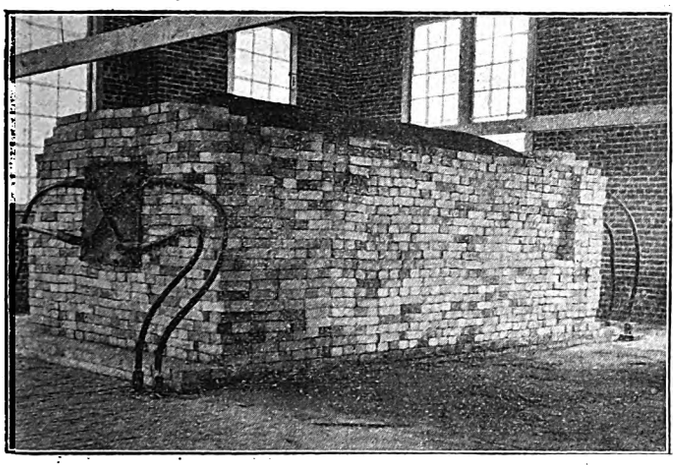

FIG. 1.—Carborundum Furnace at Niagara, before firing.

dimensions of the furnace are about 15ft. long, 6ft. wide and 5ft. high. Connecting with the inner surface of each plate are 60 carbon rods, each of which is about 30in. long and 3in. in diameter. The rods project through the walls of the furnace and form the terminals. When the furnace has been built up in this way the mixture is introduced, about ten tons making the charge. Through the centre of the mixture a core formed of small grains of coke is built, and this serves to form a continuous electrical connection between the terminals. When the current is turned on the core is soon raised to a high temperature. About an hour after the application of the current,

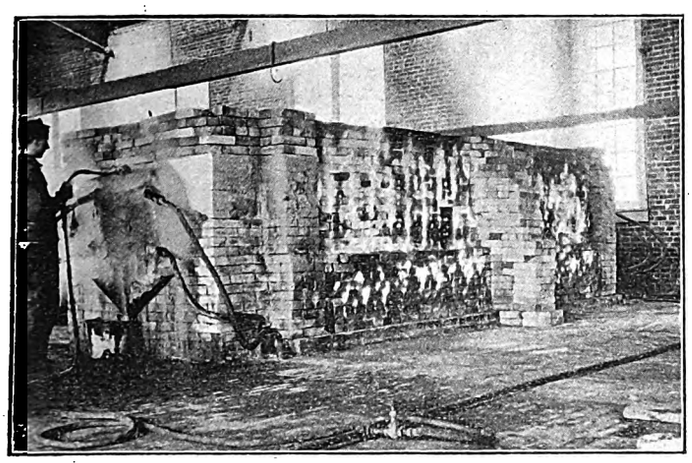

FIG. 2.—Carborundum Furnace in operation; flames on side; man keeping down temperature of terminals.

carbon monoxide gas is given off freely, and when a lighted match is applied this burns with the well-known lambent blue flame and envelops the whole furnace (Fig. 2). The current is kept on for about 24 hours, and then the furnace is allowed to cool down, after which it is opened. When this is done it presents an appearance beautiful in the extreme, the core (*see* Fig. 3) being surrounded by a cylinder of beautiful carborundum crystals varying in colour from yellow to violet. The crystals in immediate contact with the core are in one solid mass; as the distance from the core is increased, the size of the crystals rapidly diminishes, until at about 15in. all crystallisation ceases and an amorphous material is encountered of a whitish gray colour, for a distance of two inches, when suddenly a black mass composed of the original mixture, now held together in a cemented state by the fusion of the salt, is met with. The crystalline and amorphous material, lying between the core and the outer black mass, is carbide of silicon (C_2Si_2). About two tons of carborundum is produced in one run. It is at once noticed that the core is changed in appearance. It now has a somewhat metallic lustre, all impurities have been driven off and a very pure form of graphite remains. This may be an important by-product of these furnaces. The presence of graphite denotes that the temperature, when the current was on, must have been nearly 7,000°F., which is the point of graphite formation. The makers of carborundum, however, take pains to keep the temperature of their furnaces under 7,000°F., care being taken that it does not run too high, as carborundum is at its best when the furnace work is done between 6,000°F. and 7,000°F.

The product of the carborundum furnaces at Niagara have been a thorough surprise to the discoverer and all others interested in the plant. The yield of the furnaces has been most pleasing, and in some of them truly magnificent crystals three-quarters of an inch across have been found; the largest ever produced in the furnaces at Monongahela City never exceeded one-quarter of an inch.

To prepare the carborundum crystals for commercial use they are ground down in a mill, treated with sulphuric acid to

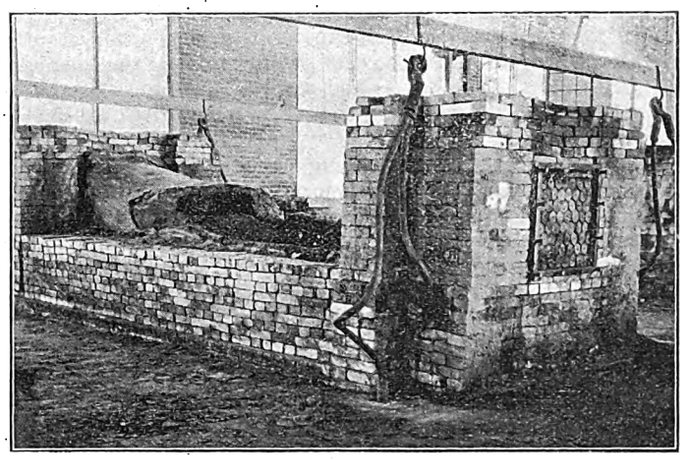

FIG. 3.—Carborundum Furnace, partly discharged, showing central core of carbon, with shell of carborundum crystals.

remove impurities, washed, sifted and stored away to be sold in the form of powder for diamond polishing, lens grinding, &c., or made up into various forms such as wheels, hones, slips, files, rub stones, knife sharpeners, scythe stones, and cloth.

The current for the furnaces at Niagara Falls is supplied from the Niagara Falls Power Company's dynamos, and comes to the factory by an underground cable at a potential of 2,200 volts. In the transformer room at the carborundum factory the potential is reduced to 185 volts. When the current is first turned on it is regulated to the full voltage. After about two hours the resistance of the furnace has become reduced sufficiently low to take a current of about 3,000 amperes at this voltage. When this point is reached the regulation is carried on carefully, so that as the resistance of the furnace decreases, the potential of the current is reduced sufficiently to keep the supply of energy to the furnace at about 746 kilowatts. The dimensions of the core of the furnace are so adjusted that when the current reaches about 7,000 amperes, and the regulation can be carried no further, the resistance of the furnace has become constant. This constant state is reached about four hours after starting, and for the remaining 20 hours the furnace is supplied with a current of about 7,000 amperes at a potential of 105 volts. Both the transformer and regulator were built by the General Electric Company. The former is the largest in the world, weighing 12 tons, and having a capacity of 830 kilowatts. The

Digitized by Google

regulator alters voltage by varying the inductance in the circuit. A small pump, run by an electric motor, keeps oil, which is cooled by a coil of pipe carrying water, constantly circulating through the transformer and regulator.

The extreme hardness of carborundum is very nicely illustrated by the story of an early experiment made by Mr. Acheson. Said he to your correspondent: "I made the first test in diamond cutting with carborundum myself. I mounted a disc of iron in a fast-running lathe and charged the surface with fine carborundum crystals. I then pressed a diamond ring against the revolving disc, and in four or five minutes the facet, which had been pressed against the disc, was found to be devoid of lustre, of a milky colour, and scored with lines. The second test was made in a diamond-polishing establishment in New York. This experiment was satisfactory in its way, but my diamond did not look nice, and I wanted it to be repolished. I therefore asked the proprietor of the works to polish the diamond, using carborundum powder instead of diamond dust. He consented to do this under certain conditions. A new lap was to be used, free from all diamond powder; my material would be tried first, and if successful I would have to pay nothing, while if unsuccessful diamond powder was to be substituted for the carborundum, and I would have to pay $5 for the work. The new lap was mounted and a workman commenced to polish the diamond with carborundum powder. Within 20 minutes all lines were removed from the facet, and it was restored to its former beauty. This was a surprise to the proprietor of the place, but none the less so to me."

On account of the remarkable hardness of carborundum, it is a more valuable material than either emery or corundum. Up to the present the Carborundum Company has been unable to manufacture sufficient of its product to meet the demand for large wheels. The buyers and users of these appear to be well satisfied with them, stating that their superiority over emery is very apparent.

Not long ago an interesting experiment of the grinding qualities of carborundum was made by a large iron firm in this country. A large roll of iron was nearly half an inch out of true, and under ordinary circumstances it would have been recast, as the labour of grinding it down by means of emery would have been too great. It was thought that it offered an excellent opportunity to put carborundum to a really severe test, so the mineral was used to turn up the roll. The result was highly satisfactory, for it was found that the work was done in just one-twelfth of the time that would have been required had emery been used.

It is interesting in this connection to note that while the primary value of carborundum is found in its industrial uses, it is none the less worthy to be placed among our jewels, for this beautiful application of electricity has resulted in developing a gem possessing the colours of all gems and the hardness and refractive powers of the diamond.

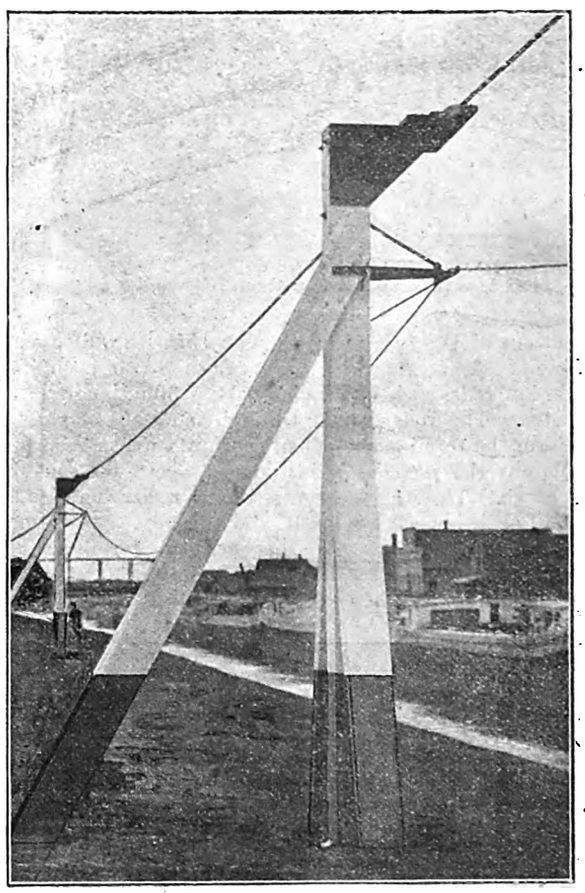
The carborundum furnaces as they stand at Niagara to-day are the greatest power consumers in the world. At a given signal 1,000 H.P. of electrical energy is turned into the granular core already referred to, and there, within a space 9ft. long and 21in. in diameter, which is the size of the core, it is converted or transformed from electrical to heat energy—a remarkable amount of work to be performed in so limited a space.

ELECTRIC PROPULSION OF CANAL BOATS.

BY ORRIN E. DUNLAP.

Considerable attention is now being given in the United States especially in New York State, to the electrical propulsion of canal boats. The device with which experiments were made on October 26th near Tonawanda is the invention of Mr. Richard Lamb. In the first test, which took place near Rochester, New York, on November 18, 1893, the "Frank W. Hawley," an ordinary canal boat, was equipped with a dish-pan screw, and was propelled by electricity by a motor on board, the current being conveyed from the central station by two wires suspended above the waterway, and was received by the motor on the deck of the boat through two underbearing trolley poles. While this test was a success in some ways, it was clear that for successful canal transportation the water in the canal must only be used for floating the boat, and the propelling device or application of power must be foreign to the water.

On the 26th ult. the experimental line was 1·21 miles long and erected along the south bank of the canal at a point where the water is 8ft. deep. The poles are set 125ft. apart. Upon the poles are brackets, as shown in the accompanying illustration, and upon them are saddles having insulating material between them. The saddles are designed to prevent short circuiting of the electric current by rain. A bracket is also provided to support the lower or traction cable. This is not insulated, but at intervals along the line some of these brackets are grounded. A 1¼in. cable of the hardest crucible steel, having a tensile strength of 132,000lb., and weighing 3·67lb. per foot, is supported upon the upper saddles and a ⅝in. steel cable upon the lower. The bearing cable is placed at an elevation of 16ft. from the ground, and the traction cable 3ft. below it. The motor truck is made with two deep-grooved wheels to run on a cable, having a horizontal



Lamb Electric Cable-Hauling Pole on the Erie Canal.

axle between them and below their centre line. Upon the axle is suspended a hanging frame, having attached to it an elliptically-grooved sheave, which is revolved by means of a worm or wedge-gearing, driven by a 25 H.P. electric motor, with vertical shaft, weighing 1,200lb., all attached to the swinging frame of the car. By taking three turns of a ⅝in. cable around the elliptical-grooved sheave, when the electric motor revolves the gearing, the sheave winds up, and at the same time pays out on the ⅝in. cable, thus pulling along the car. The motor in this way gets its tractional friction independent of the weight of the apparatus. The current is returned through the traction cable, which is grounded at intervals, giving a combined ground and metallic conductor for the return current. A 500-volt current is used. It is taken from the main cable through the wheels, thence through the axle to the axle box of the hanging frame. Here an insulated copper wire connects it with the rheostat on the barge. Four insulated copper wires, armoured with steel wire, form the cable that conducts the

Digitized by Google

current from the bearing cable to the rheostat on the boat and back to the motor, and at the same time acts as the tow line. From the motor the current goes to the axle of the elliptical groove wheel, thence to the $\frac{5}{8}$in. wire rope, thence to earth. When a motor is to be run without any boats in tow its rheostat and conducting-wire-tow line is placed upon the motor, and a driver seated on a seat on the electric mule operates the same.

The power for the trial of the 26th was obtained from the station of the Buffalo and Niagara Falls Electric Railway. Mr. Richard Lamb acted as motorman, and, after the invited guests had, by their weight, loaded down a large canal boat, he opened the lever that set his "electric mule" in motion, and it at once started up the canal against a strong wind and current, towing the loaded boat at good speed. It ran rapidly to the end of the line, the speed being about three and three-fifths miles per hour. On the return trip the motor drew five boats loaded with people along at the rate of four and seven-tenths miles per hour.

STREET LIGHTING BY ARC LAMPS.*

BY ANDRÉ BLONDEL.

(Concluded from page 42.)

Candle-Power of Lamps.

All the arrangements which I have just reviewed have in actual practice one common fault—that is, the very considerable distance between the lamps, which makes the distribution of light very unequal. This is even one of the arguments against the use of arc lamps which the partisans of incandescent lamps make much use of. This inconvenience is the consequence of the use of powerful lamps (without speaking here of the naturally bad law of distribution of the rays). It may be asked if we cannot reduce this by using less powerful lamps; for instance, lamps of 4 to 6 amperes, which are to-day not at all used in public streets in France, and in particular in Paris, where no lamp taking less than 10 amperes is used. We find sufficiently numerous applications of them in other capitals, as is shown by Table V., to demand that the subject shall be given more attention. The city of Munich, for instance, already uses 48 lamps of 5 amperes; so also at Turin, the public lighting comprises 115 arc lamps of 6·8 amperes by the side of 155 taking 9·6 amperes. At Milan some arcs of 4½ and 6 amperes are also in use. I believe, then, that there are conditions calling for the use of large and of small lamps in electric lighting, as well as in lighting by gas, when properly proportioned, of course. At first sight everything seems to resolve itself in favour of large lanterns, and it is, in short, the current opinion that in lighting by arc lamps one ought to endeavour to reduce the number and to increase their intensity. There are in this two good motives: on the one part the luminous product—that is to say, the ratio of the luminous flux produced to the energy employed—increases with the intensity of the current; on the other part the price of the pillars and of the lamps and the daily up-keep are the same whatever is the power of the lamp. But if we examine the question closer we perceive that the expenses under this head do not in practice enter into the question, except as a very small fraction, while the energy consumed plays an altogether preponderating part in the determination of the annual cost.[31] From this it follows that the variation of the annual price per lamp does notdiffer very much from the law of proportionality with the current.

At Milan it has been possible to fix the following prices to be paid by the city to the Edison Company, prices which to us appear to be very instructive[32]:—

Lamps of	4·5 amperes	.....	0·24 francs	per lamp-hour.
„	„ 10·0 „	.....	0·35 „	„
„	„ 20·0 „	(2 in series) ...	0·75 „	„
„	„ 40·0 „	„ ...	1·50 „	„

In Paris we may be allowed to suppose that the city, which pays 40 centimes per lamp-hour of 10 amperes, might easily treat on this basis for lamps of 5 amperes for 25 centimes per hour, for the candle-power of the lamps varies with the current following a parabolic law sufficiently near to proportionality. We may calculate this provisionally from the numerous measurements of the Antwerp Exhibition and the formula of Palaz[33]:—

$$I^{max} = 20\,i + 0{\cdot}4\,i^2.$$

By supposing that the form of the curve and the effect of the globes remain similar for all intensities, which is very approximately correct, we find thus:—

Amperes.	Maximum intensity in pyrs.	Practical hemispherical intensity.	
		With naked arc.	Under ordinary opal globe.
5	1,100	650	300
6	1,200	800	470
8	1,900	1,100	640
10	2,400	1,400	520
12	2,980	1,750	960
15	3,900	2,300	1,350
20	5,600	3,250	1,900

By substituting lamps of 5 amperes for those of 10 amperes we see that for equal cost the total useful luminous flux is reduced in the ratio

$$\frac{2\times 110}{240}\times\frac{40}{2\times 25} = 0{\cdot}73,$$

but the distances between the lamps would be reduced, on the other hand, in the ratio $\frac{25}{40} = 0{\cdot}625$.

The second solution may then be better than to the first because the diminution of the total flux makes itself above all felt by the reduction of the superabundant lighting, and because the minimum lighting, on the contrary, is augmented. This we believe to be the case more especially when the width of the street is small. It is then very bad practice to put, as is often done, arc lamps of 10 to 12 amperes in streets of 8 to 10 metres in width, with distances between them of 40 to 60 metres. One would prefer in this case arcs of 5 or 6 amperes, spaced at 20 or 30 metres. This last arrangement has besides the advantage of reducing the effects of contrast. Many cities, especially provincial ones, would find it to their interest to adopt lamps of 5 to 8 amperes, instead of lamps of from 10 to 15 amperes, which are to-day almost exclu-

* From *Le Génie Civil*. Translated by Mr. John Hesketh.

[31] This may be represented by an expression in the form

$$p = A + (B + C)\,E,$$

A and B being two fixed coefficients and E the energy consumed. A comprises the sinking fund of the capital employed (lamp-posts and accessories, connecting, fixing, &c.), the cost of up-keep and the salaries of lamp-lighters and cleaners. B is the price of the energy, in kilowatt-hours. C is the additional expense for carbons (which is sensibly proportional to the energy). For an equal output of energy, the cost of the laying of the principal mains (with which we do not trouble ourselves here) may be regarded as being independent of the number of the lamps, the cost of the branches increasing, on the contrary, proportionally to the number of lamps. If H is the number of hours the lamp is used annually, we have as the price per lamp-hour

$$\frac{p}{H} = \frac{A}{H} + (B + C)\,W,$$

W being the power in kilowatts absorbed by the lamp. The first term will be much smaller relatively to the second as the number of hours the lamp is used increases. I find the following results, for instance, at Paris, from figures very kindly communicated to me by M. Clerc, Director of the Drouot Station, and M. Soubeyran, Director of the station of La Rue des Dames:—

Lighting of the Avenue de Clichy.

H = 3,749 hours, A = 0·05, C = 0·0135;

from which $\frac{p}{H} = 0{\cdot}06 + (0{\cdot}0135 + B)\,0{\cdot}49$ kilowatts (the lamps working at 49 volts.

Lighting of the Grand Boulevards, Edison section.

H = 2,610 hours, A = 0·068, C = 0·024,

from which $\frac{p}{H} = 0{\cdot}068 + (0{\cdot}024 + B)\,0{\cdot}55$ kilowatt.

The city pays 0fr. 40C per lamp-hour, or eight times the amount of the fixed charges. The cost of the energy is thus preponderating. By applying the same formula we find that for a lamp taking 5 amperes at the same voltage,

$$\frac{p}{H} = 0{\cdot}06 + \frac{0{\cdot}34}{2} = 0\text{fr. } 23\text{c},$$

and

$$\frac{p}{H} = 0\text{fr. } 234\text{c}.$$

These formulæ made the price per kilowatt-hour come out at 0fr. 70c and 0fr. 60c about, figures which are lower than the mean total nett cost estimated by M. Maréchal (about 1fr. for the Clichy section), but probably higher than the nett cost of the supplementary kilowatt-hour. For companies, public lighting may well be more expensive, because it constitutes a valuable advertisement. It is almost everywhere the same, and municipalities may reasonably profit by this circumstance to obtain good terms for the lighting of their public roads, the only service which directly interests all their constituents.

[32] I am indebted to the kindness of Signor C. Cervi for these returns.

[33] *Traité de Photometrie*, p. 223.

Digitized by Google

sively in use.[34] This would only be the extension to public lighting of the movement which was made in favour of small arcs for private electric lighting some time ago.[35]

All these principles I have just expounded with regard to public lighting, apply, with very slight modifications, to the lighting of large spaces of all kinds; in particular of halls, quays, goods stations, &c. Although this investigation is rather removed from my subject, I would like to mention, in passing, two points which appear to me interesting from my present point of view. First, the sometimes preponderating importance that one may be led to give to the vertical illumination; when reference is had more particularly to lighting roads and waggons, the surfaces it is most useful should be well seen being vertical surfaces. Second, the necessity of examining carefully what are the really useful parts of the luminous flux. In an enclosed space, but with a glazed roof, such as a hall, we can consider as useful the flux which falls not only on the ground, but also that which falls on white diffusing surfaces; a greater elevation of the lanterns may therefore be justifiable. On the contrary, for the lighting of uncovered ways all the rays which pass higher than the waggons are lost, and it is therefore a matter of first importance to lower the lanterns or to concentrate their rays at a lower angle by appropriate means, such as those of which I shall speak later.

II.—Physiological Principles.

The value of public lighting cannot be calculated simply, as we have supposed, up to this point from the illumination measured by the photometer, because measurements of this kind do not take into account all the physiological effects which accompany the phenomena of vision. These have for their origin, first, the "diaphragmation" of the pupil—that is to say, the property which the pupil possesses of contracting or dilating instinctively to regulate the quantity of light admitted on to the retina. We know that with the cat "diaphragmation" takes place during the day, even up to the complete closing of the eye. Doubtless it is this fact which allows this amiable animal to preserve the exceptional sensibility of vision for its nocturnal promenades. The diameter of the pupil of man being able to vary on an average from 10mm. to 2·5mm. for the same individual, we see that the surface of admission and consequently the quantity of light received by the retina may vary in the ratio from 1 to 16. An object may then, as I have already shown many times,[36] appear 1 to 16 times more luminous for an equal photometric lighting, according to the opening of the pupil. Again, this opening regulates itself instinctively according to the intrinsic brilliancy[37] of objects situated in the field of vision, and varies in an inverse sense to that brilliancy. We can then, according as one gives to the luminous source little or much brilliancy, realise, with the same quantity of light, a good or bad useful effect on the retina.[38] This effect is easy to demonstrate practically. It is sufficient to look at a room or place illuminated by a brilliant source of light placed in the field of vision, shading and unshading the source alternately by a little screen so as to suppress or re-establish its direct action on the retina. We find a much more satisfactory illumination when the light is shaded. The popular expression that a brilliant light has a "blinding" brilliancy thus only translates this fact of instinctive experience. Second, *contrast*—that is to say, the well-known phenomenon which makes objects situated in the immediate proximity of an illuminated object appear proportionately more obscure than they really are, and still more obscure as the brilliancy of the latter is greater. These two psycho-physical phenomena which modify, the first the absolute and the second the relative, value of apparent illuminations, may make simply physical measurements completely illusory, and all comparisons made without taking them into account are very debatable. This explains the singular fact, very often mentioned and repeated at the commencement of this article, that an absolute increase of light does not always give rise to a relative increase in public satisfaction. Let us replace, for instance, lighting by gas by lighting by arcs, and give 20 to 30 per cent. more total luminous flux. Very often the public will complain and demand an increase in the number of lamps. This is a fact that it is necessary not to lose sight of when it is desired to substitute electricity for gas. The effects of contrast ought to make us not only avoid sources of light of too brilliant a nature, but should make us seek the *uniformisation* of illuminations, for surfaces lighted too brilliantly make the rest appear too obscure. This phenomenon applies more particularly to narrow streets: close to the lamps the façades of the houses are brilliantly illuminated, and in the intervals between they appear black by contrast. The effect is all the more annoying the more powerful the lamps and the wider they are apart. Here, then, is a very important reason for the adoption in our streets of lamps of a candle-power conveniently proportioned so that the space between them may be somewhere about double the width of the streets they light, as I have explained previously. It is one argument the more in favour of lamps taking 5 to 8 amperes. Two very distinct things are, in short, necessary to effect a good public lighting. First, to produce a photometric illumination as satisfactory as possible with a given quantity of light, losing as little as possible of the flux produced. Second, permit the eye to take in as great a part as possible, offering to it only surfaces of feeble intrinsic luminous brilliancy (which obliges us to diffuse light), and, shunning the effects of contrast. In other words, it is important not only to obtain a fixed minimum illumination, but, above all, to realise harmony in lighting. This is often expressed in a vague form when we say it is necessary to realise a good "effect." We are far, as we shall see, from having yet arrived at this harmony in any complete manner so far as our present arc lighting is concerned, and we too often neglect to trouble ourselves about this effect. By knowing how to calculate this beforehand we should very often have been able to considerably reduce expense, and still have obtained the same apparent result.

Conclusions.

We have seen from all the preceding discussion that the conditions generally admitted as bases of schemes of lighting are insufficient, and that it has been necessary to complement them by the consideration of the superabundant illumination. I have come to the conclusion that it would be well to impose the following conditions: Firstly, a mean illumination of the roadway, or, better, a mean illumination of all the usefully illuminated surfaces E_m; secondly, a minimum horizontal illumination at the height of the roadway, E_H; thirdly, a minimum vertical illumination at a certain height—to simplify matters, we may be content to take this illumination at the height of the roadway; fourthly, a mean superabundant horizontal illumination, E_s, in a circle; with a radius of 5 metres, for instance, described round the lantern at a height of 1·50 metre above the ground; fifthly, an excellent diffusion of the light—that is to say, the use of sources of low apparent brilliancy and of intensity proportioned to the width of the street to be lighted. The first condition prevents us being niggardly in the quantity of light furnished and from raising the lanterns too high. The second permits of a minimum degree of visibility being assured on the roadway. The third assures a good illumination of foot passengers and vehicles. The fourth is that which answers to the public taste by giving to them a good sensation of light, so that they are able to read printed matter at the foot of a lamp-post. It prevents, also, the use of too high lanterns. The fifth is absolutely necessary to allow the eye to take in the greater part of the light furnished, and to avoid the disastrous physiological effects just pointed out. The four photometric conditions are in reality always more or less connected, but this connection is too complicated to allow the conditions to be reduced to three only. It is a delicate matter to fix the values to be adopted for the different constants, because of the continual increase of the standard pointed out at the commencement of this article. I have previously indicated as values of the mean illumination to be obtained for secondary streets, 1·5 lux; for important streets, 2 lux. The railways of the Belgian State have even been content with 0·2 lux in lighting their stations, but to-day these figures have already been well exceeded, so that the best way is to be guided in all cases by the figures obtained from existing lighting in cities of equal importance to that to which the scheme under consideration refers. In the particular case of lighting by electric arcs, the following figures, which we have borrowed from M. Maréchal and Herr Wedding, or which I have calculated in a somewhat similar manner, will be of service as a preliminary indication, and will complete those I have given higher up for the spacings and heights.[39] These figures

[34] The use of large lamps may, however, be advantageous in the case where energy is at a low price, and where the cost of carbons and manual labour assume greater importance. This happens, for instance, in lighting railway stations where the current is produced by the company itself.

[35] This conclusion only applies to continuous currents. With alternating currents one is led in general to adopt higher candle-powers, and I explained this (*Lumière Electrique*, October, 1893) by the instability and bad efficiency of small alternating arc lamps. A lower current than 8 amperes is not to be recommended for these, and the best conditions of working can only be realised with arcs of at least 10 to 15 amperes. I will refer again in greater detail to this question of alternating arcs.

[36] *See* more particularly *Les Comptes Rendus de la Société Française de Physique*, 1894, p. 84.

[37] The intrinsic brilliancy at a point is the ratio of the normal luminous intensity produced by a small surface of the lighting body to the area of that radiant part.

[38] M. Charles Henry has contributed an important series of articles to *L'Eclairage Electrique* (November and December, 1894); a complete study of the phenomenon of which I here only mention the principle.

[39] For all cities other than Paris and Berlin it has been impossible for me to obtain sufficiently precise returns to allow even an approximately accurate evaluation. There are as yet, unhappily, only few engineers who interest themselves in this measurement. The first serious photometric tests were initiated at Berlin.

do not take into account the light diffused by walls; they are then rather lower than the reality:—

TABLE VI.—*Examples of Illumination obtained.*

Constant.	Paris.					Berlin.
	Avenue Clichy. (At 4·95m.)	Boulevards Section Popp.	Rue Royale. 1°	Rue Royale. 2°	Boulevards Section Edison.	Unter-den-Linden.*
	Lux.	Lux.	Lux.	Lux.	Lux.	
E_m	2·19	3·35	3·40	3·38	1·98	...
E_H	0·18	0·49	0·50	0·70	0·33	3·5, about.
E_V	0·16	0·46	0·43	0·66	0·24	...
E_s	16 to 20 lux at 1·50 metres in height.					12 lux at 1·50 metres.

* In the part where there are two rows of arcs.

The highest illuminations which have ever been attained in France seem to be those of La Rue Royale in Paris. These constitute in the actual state a maximum which it is interesting to know. I reproduced the plan of illumination which M. Maréchal has calculated in this case[40] (Figs. 28 and 29). We may compare these with the results given by Herr Wedding for the lighting of the promenade of Unter-den-Linden at Berlin, Fig. 30, which I have borrowed from his work. This represents (in German candles at one metre), the distribution of horizontal illuminations on a plane taken at 1·50 metres above the ground between two lamps of 14 amperes fixed in the centre of the street at a height of 8 metres. It should be noticed, in making the comparison, that one German candle equals 1·22 pyrs. Other figures make the minimum illumination following the axis of the street to be 5·5 lux at 1·50 metres above the ground. Working back we find this illumination on the ground is about 3·6 lux. We thus see that the lamps employed at Berlin, being at the same time more powerful (14 amperes instead of 10) and nearer, the illumination obtained is actually superior to that obtained in La Rue Royale. It is probably exceeded by that of the Fifth-avenue at New York, about which I have not, unfortunately, been able to obtain complete information.

Another question arises now; it is this: On what principles should we conclude a bargain with a company for the furnishing of light? or, in other words, What is the merchandise for which we should bargain? Hitherto two systems have been employed; the older consisted in paying for the light at so much per carcel. The more modern consists in paying for the energy at so much per kilowatt-hour. The first system gives rise to much annoyance because of the equivocal manner in which the contracts were drawn up, the expression "carcel" signifying nothing in itself if we do not define the direction in which the intensity is to be measured.

[40] We must add that these figures are rather lower than the reality, for M. Maréchal has wittingly left out of consideration the supplementary effect produced by the arcs on the refuges (*see* Fig. 26).

Digitized by Google

This precaution has been taken in some cities,[41] but in many others, notably in Paris, it has been omitted. Under these conditions one was in the hands of the *concessionnaire*, who might at any time pretend that the stipulated intensity referred to the direction of the maximum, following a very convenient habit of gas engineers.[42] To put an end to these discussions we have been led to entirely suppress photometry, and to define the lamps by their current.[43] This is the system adopted at the present day in almost all the new installations. It is seductive in its simplicity, for it lends itself to easy control. But this method presents grave inconveniences which are not always sufficiently recognised. It conduces to a bad utilisation of the energy. In short, there being no clause imposing on the *concessionnaire* a good luminous efficiency, he has no interest in getting a better effect out of his lamps. He will employ, then, by preference, carbons of a larger diameter to reduce the frequency of their renewal, which lowers in an enormous proportion the luminous return,[44] and he will no longer seek methods for utilising the light emitted by his lamps towards the sky. Thus in France there is not at present, to my knowledge at least, a single installation of public lighting by alternating arcs which is satisfactory from the photometric point of view.[45] They all waste half at least of their light, and the *concessionaire* is completely careless about the matter. It would no longer be the same if another mode of evaluation were adopted. The only logical method is the useful luminous flux, which, from what we have already seen, is easily confounded in practice with the lower hemispherical flux. The true basis for a contract for lighting should be then, the quantity of light emitted below the horizon, measured in lumen-hours,[46] just as the energy is calculated in watt-hours. It is, in short, on the number of lumens that the number of square metres to which one may give a fixed mean illumination depends. Practically many criticisms may be raised against this method because of the difficulty of verifying the figures. But it is easy, I think, to avoid this objection by the following combination, which restores the control to where it should be.

1. The contract should be entered into for a certain number of hemispherical lumen-hours per lamp.
2. The *concessionnaire* should then have his type of lamp approved and should explain the conditions under which it is his intention to produce the light and furnish an experimental proof of it by measurements such as are made by the Contral Laboratory of Electricity, whose certificate would be accepted. The fixed quantities would be: the voltage at the terminals, the value of the current, and the diameter of the carbons—which it is a great mistake never to indicate in contracts.
3. These three factors once settled, they can easily be verified so long as the *concessionnaire* does not propose any modification.
4. At each modification of the apparatus, methods or appliances for the production of *the light*, the *concessionnaire* shall notify the new constants and shall have them certified as at the first.
5. If it can be shown that the proposed modifications permit a reduction in the expense at the same time as they produce the same useful flux of light, the city and the *concessionnaire* shall share in halves or in such other proportion as may be arranged the nett economy thus realised.

This combination, as we see, does not in any way complicate municipal lighting, since testing at the expense of the *concessionnaire* will not be repeated except he finds it to his interest, and the municipal control is practically the same as in the case of a contract for energy. On the other hand, this arrangement leaves the way open to progress, and in contradistinction to the greater number of existing contracts, it offers a premium upon the best utilisation of light and upon the employment of means for permitting the light actually lost in the clouds to be sent towards the ground.[47]

[41] For instance, this measurement is taken for the angles 45deg.—55deg. at St. Petersburg, 60deg. at Berlin (these angles being measured from the vertical).

[42] Gas lamps are ordinarily defined by their maximum intensity, which with some is in a horizontal direction, and with others (Wenham, for instance) in a vertical direction, and it is to these figures that one refers in comparing the consumption of different burners.

[43] American engineers and some European engineers have chosen another very original and not less debatable method to simplify this question. They have decided to officially call every lamp taking 10 amperes a lamp of 1,000 candles, even if it only gives 500 or 600 candles, as is ordinarily the case. The utility of such an arrangement is hard to understand, for it is but a useless fiction; from the moment when one ceases to take photometric measurements it is far better to frankly keep to the indications of the electrical constants.

[44] This fact is well known to all those who have used the electric arc. As a typical example I, however, believe it will be useful to quote a practical recent trial made in America, and which has furnished the following figures:—

Kind of carbons.	Dia. Mm.	Time. h. m.	Energy consumed. Watts.	Horizontal Candles.	Ratio of candle-power to energy. Candles per watt.
Union carbon (cored)	11·5	18 53	361	159	0·44
Union carbon (cored)	11·5	12 0	424	316	0·75
Washington carbon (solid)	11·5	9 14	445	359	0·80

The return of light varies, then, almost from single to double, according to the length of time.

[45] I shall return later to this interesting question.

[46] M. Hospitalier proposed calling this the "illumination" (*eclairage*).

[47] At Toulouse the authors of the 1891 contract, who have foreseen a possible modification of the methods of lighting, independent of the processes of production of electricity, have adopted a different wording as follows: "If a new method, apparatus, or appliance shall permit of the reduction in an appreciable proportion of the number of watts necessary for the production of the same quantity of light, the City shall have the right to require the application of the method, apparatus or appliance to the municipal lighting. The watts thus saved shall be employed in feeding new lamps fixed according to the indications of the Mayor." This clause, which some engineers may be inclined to prefer to the one I propose, is excellent in theory, but it has three inconveniences in practice:—1. It does not specify in a sufficient manner that which is to be understood by quantity of light. 2. The form of carbons not having been defined, the company is at liberty to modify them at will to increase their duration without the city being able to interfere, despite the loss of light which would result. 3. The installation of new lamps being at the cost of the *concessionnaire*, he has all to lose and nothing to gain by the anticipated improvements, which can be of advantage to the City alone; far from proposing them, he would seek to avoid them being known and adopted. The wording given by me appears better, and is possibly more equitable, for if the contract is drawn up as it should be to-day—that is to say, on the principle that the public lighting constitutes a sort of "paying advertisement" for the company undertaking it—they ought to expect under this head a more or less large annual loss, and it is only just to let them have the chance of reducing this at the end of a few years.

DOUBLE REFRACTION OF ELECTRIC RAYS.*

BY PETER LEBEDEW.

Ever since Hertz gave us the means of experimentally investigating the consequences of the electromagnetic theory of light, it has been felt desirable to carry out these experiments on a smaller and more convenient scale. The first researches in this direction were made by Prof. Oliver Lodge[1] and more recently by M. A. Righi[2], who worked out a method which has now found various applications. By further reducing of the apparatus I have successfully generated and observed waves which could only be measured by fractions of a centimetre ($\lambda = 0{\cdot}6$cm.), and which come nearer the longest waves of the heat spectrum than the electrical waves originally employed by Hertz. For these experiments the parabolic mirrors can be made so small that prisms of a little over a centimetre are quite sufficient for the demonstration of refraction. It was thus made possible to bring the fundamental experiments of Hertz within the sphere of ordinary optical instruments, and to complete them by showing double refraction in crystals. In what follows I shall first describe these experiments, and shall give the technical details in the supplementary paragraphs. It may be remarked here that M. Righi,[3] by proving circular polarisation in wood blocks, had already discovered the phenomenon of double refraction.

I.—The Apparatus.

In selecting the experimental arrangement, the classical one of Hertz served as a model. The oscillations were generated in the focal line of a cylindrical mirror. In the focal line of the receiving mirror there were two straight-line resonators which were excited by the waves falling upon them, but the linear dimensions were all reduced 100 times. Such a reduction, however, could not be brought about without some alterations, and, therefore, for the primary conductor the form given by M. Righi was adopted, and the excitation of the resonators was not measured by means of a secondary spark, as in the Hertz method, but in the thermo-electrical way of J. Klemencic.[4]

The primary conductor (Fig. 1) consisted of two platinum cylinders P and P_1, each 1·3mm. long and 0·5mm. thick, which were fused

into the glass tubes G and G_2. The current was led in by sparks passing from the wires D_1 and D_2 to the platinum cylinders. This primary conductor was placed in the focal line of a circular cylindrical mirror[5] 20mm. high, with an aperture of 12mm. and a focal distance of 6mm. In order to have the sparks of the primary conductor passing through a liquid insulator, the whole mirror was placed in a petroleum bath, which was provided with a small mica window to allow the rays generated to pass undisturbed into the open. A suitable screw permitted the regulation of the length of the primary sparks ($l = 0{\cdot}02$mm.). The current was taken from a medium-size induction coil (30 interruptions per second), in the secondary circuit of which was placed a condenser C and a water resistance W, for the purpose of protecting the primary spark from the damaging after-discharge of the coil. By means of a second mirror of parabolic-cylindrical shape with a focal length of 1·4mm., a height of 20mm., and a 12mm. aperture, and which was built exactly like a Hertz mirror, the rays were concentrated on to two straight-line resonators of 3mm. length. On to the opposing faces of these resonators, R_1 and R_2 (Fig. 2), very

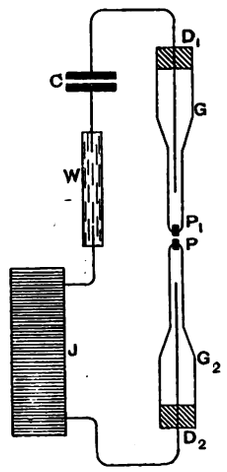

Fig. 1.—Full Size.

thin wires (diameter = about 0·01mm.) of iron and *constantan* respectively were soldered in such a way that two loops of 0·33mm. were formed. To the middle of each resonator (that is to say, at the nodal point of its electrical oscillations) was soldered an elastic leading-in wire, fixed to the ebonite plate E. When the resonators are excited a discharge takes place at each oscillation, partly through the wires of the thermo-element, the heating of which was indicated at once by a very sensitive galvanometer (one scale division = $6{\cdot}10^{-9}$ amperes; resistance = 0·62 ohms) and measured by its first deflection. To protect the delicate thermo-element from air currents the secondary mirror was surrounded by a cover having a mica window. Both mirrors stood on a spectrometer. The focal line of the primary mirror was in a fixed vertical position, while the secondary mirror was fixed to a movable arm of the spectro-

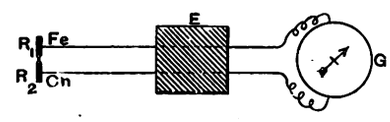

Fig. 2.—Full Size.

meter, and could be turned round the ray as axis. The distance of the two mirrors apart was in most experiments 10cm., which corresponds with the distance of 10 metres in the Hertz experiments. Under these circumstances the deflection of the galvanometer reaches 20 to 30 scale divisions.

II.—The Fundamental Experiments of Hertz.

With the apparatus described, the fundamental experiments of Hertz may easily be repeated.

(A) *Polarisation.*

For the polarisation experiments I employed a square grating of 2 × 2cm., consisting of 20 fine wires. The behaviour of the grating with the lines parallel or crossed was identical with that discovered by Hertz. The extinguishing effect of the grating is of importance, as it indicates at once the existence of disturbing effects (such as the direct distant influence of the induction coil on the galvanometer). In all the further experiments described below, a larger polarisation grating was placed in front of the primary mirror, and each observation was repeated with the grating in two positions. The difference in the galvanometer deflection could only have been conditioned by the electrical oscillations which passed through the grating.

(B) *Interference.*

The length of wave used can without difficulty be determined by the method of L. Boltzmann,[6] employing two flat mirrors. The maximum, which appears at a distance of 0cm., is followed by a well-defined minimum at 0·2cm. to 0·3cm., and this again is followed by a weak maximum at 0·5cm. to 0·6cm. At greater differences of phase no periodical fluctuations are perceptible, which is a proof that the wave examined is heavily damped. From these observations the wave length may be taken $\lambda = 0{\cdot}6$cm., which corresponds with the geometrical measurement of the apparatus.

(C) *Rectilinear Propagation.*

If the mirrors are placed 10cm. apart, experiments on the transparency of insulators, ebonite, mica and glass, and the screening effect of conductors (metals), can easily be made. If the secondary mirror be moved away from the primary one, the galvanometer deflections then decrease a little quicker than the distance increases. The ray has no sharp limits, but its direction can be given correctly to 3deg.

(D) *Reflection.*

For the demonstration of reflection a flat metal mirror of 2 × 2cm. is sufficient. To show the behaviour of anisotropic surfaces the polarisation grating described can be employed with advantage.

(E) *Refraction.*

To demonstrate refraction a small prism of ebonite 1·8cm. high, 1·2cm. broad, with a refraction angle of 45deg., and of a total weight of scarcely 2 grammes, was quite sufficient. In the experiment of Hertz the weight of the prism was about 12cwt. The prism was set up on the spectrometer table, and the primary mirror was placed at a distance of 3cm., while the distance of the secondary mirror from the prism was 7cm. The observation was made in the usual way for the two minimum positions. The secondary mirror was set up at different angles, and the corresponding galvanometer deflection noted. (The influence of the changing condition of the primary sparks can be diminished by a succession of frequent observations.) If the results are plotted graphically, then the position of the maximum can be determined within 3deg. It may here be remarked that a metal diaphragm 1·2cm. across, set up close in front of the prism, scarcely influences the position of the maximum in the refracted ray, though the maximum appears very much weakened. For this reason diaphragms were not used. From the deviation angle of 30, the index of refraction of ebonite was calculated to be $n = 1{\cdot}6$. The square roots of the different dielectric constants for ebonite, as furnished by different observers,[7] range from 1·4 to 1·8. Even if we, like Hertz, do not attach too great importance to the indices of refraction found under the conditions described above, yet we are entitled to conclude that in this case, within the limits of observational errors, the Maxwell law prevails.

III.—Double Refraction.

The dimensions of the apparatus described permitted of the fundamental optical experiments being made with crystal line media. Of the different crystal line materials used, the natural rhombic sulphur was found excellent for its high insulating properties, as well as on account of the sufficient divergence of the two rays. As the dielectric constants for different directions are known from the measurements of L. Boltzmann,[8] the orientation of the sections will always relate to the large (D_g), the mean (D_m) and the small (D_k) dielectric axis.

(A) *Prismatic Diversion.*

Two prisms exactly alike, 1·8cm. high, 1·3cm. broad, with a refraction angle of 25deg., were cut out of two nearly similar crystals. The refracting edge of the first was parallel to the large dielectric axis (D_g), and the edge of the second parallel to the small axis (D_k). The deviation angles of the electrical oscillations parallel to the refracting edge were determined in the same way as for the ebonite prism, and from this the index of refraction was calculated. The measurements gave the following figures: $n_g = 2{\cdot}2_5$; $n_k = 2{\cdot}0_0$. The square roots of the dielectric constants, as measured by L. Boltzmann, are as follows: $\sqrt{D_g} = \sqrt{4{\cdot}77} = 2{\cdot}18$; $\sqrt{D_k} = \sqrt{3{\cdot}81} = 1{\cdot}95$.

These experiments lead, therefore, to the conclusion that electric waves are doubly refracted in crystalline sulphur, and that also for this substance Maxwell's law holds good within the limits of observational errors. Unfortunately there was no third crystal at my disposal out of which I could have cut a prism for the determination of n_m.

[5] A circular cylinder was preferred to the parabolic shape of Hertz, on account of the greater ease of construction.

(B) *Nicol's Prism.*

The refractive indices found permit of the angle of total reflection in ebonite being calculated for the mean refractive index of sulphur, and a Nicol prism can be made for electric waves. This was done in the following way: A parallelepiped (2×1·8×1·2cm.) of crystalline sulphur, whose dielectric axes are parallel with the edges, was cut in two along a section running through D_g, and forming with D_k an angle of 50deg.; between these was placed an ebonite plate about 1·8mm. thick. A ray falling in the direction of D_m is resolved into two components, which respectively oscillate parallel to D_g and D_k, the first of which is totally reflected on the ebonite plate, while the second passes through undisturbed. With this Nicol prism the well-known optical experiments can be easily repeated.

If the mirrors are set up opposite each other with their axes parallel, then the ray is "extinguished"[9] as soon as D_g becomes parallel to the electrical oscillations. (It was proved by moving the secondary mirror, that in this case the ray is diverted.) If the prism was turned through 90deg. about the ray as axis, then the radiation passed through it, which was shown by a galvanometer deflection of 20 scale divisions. If the mirror axes are crossed, the galvanometer shows no deflection as long as the Nicol remains in the ordinary position; a turn through 45deg. is sufficient to produce at once a deflection of 15 scale divisions.

(C) *Quarter-wave Plates.*

The experiment with a quarter-wave plate, which forms the basis of all interference phenomena in crystalline plates, can easily be made in the following way: Out of a sulphur crystal is cut a square plate 2×2cm. and 0·6cm. thick, so that D_g and D_k lie in its plane. For the wave-length $\lambda = 0{\cdot}6$cm. a retardation of $\frac{\pi}{2}$ takes place in this plate. If this plate is placed between the crossed mirrors the following is then observed: If both the dielectric axes are parallel to the focal lines of the mirrors, then the field remains dark and the galvanometer shows no deflection. If now the plate is turned through 45deg., the transmitted ray is circularly polarised, and the galvanometer indicates at once a deflection of 15 scale divisions. If a second quarter-wave plate were introduced in the path of the circularly polarised ray, in such a way that the dielectric axes of both plates are at right angles to each other, then the galvanometer remains at rest, and the field is again dark.

Experiments with thicker crystal plates show no phenomena analogous to the well-known optical ones. This is easily explained by the considerable damping of the wave-motion employed. Though the experiments described are not very numerous, they are sufficient to prove the correctness of the view pronounced in 1862 by Maxwell on the behaviour of electric waves in crystalline media, and to show also the identical behaviour of electrical and light waves in this particular complicated case.

SUPPLEMENTARY REMARKS.

In my account of the experiments described above, I thought I could pass over several details which did not touch the basis of the experiments, but for the repetition of these and further investigations these details may be welcome, and I shall discuss them in the following paragraphs:—

1.—*The Primary Conductor.*

Of the different arrangements for the primary conductor, the one described by Righi was found to be the most suitable. Leads of low conductivity and dilute electrolytes in place of the Righi air-spark did not impair the effect of the primary conductor, but were unsuitable for technical reasons.

A frame, R R R R (Fig. 3), consisting of a glass tube, carried the primary conductor. The two halves, G_1 and G_2, of this latter were cemented with shellac into zinc holders. By tightening the screw V, the length of the primary spark ($l = 0{\cdot}02$mm.) could be regulated to a very fine degree. The most effective primary spark was found to be a very small one, looking like a tiny star. It may here be pointed out that the two halves of the primary conductor must be well secured, as in the formation of the primary spark the petroleum suddenly evaporates, and tries to force the two halves apart, increasing the spark distance beyond the most suitable length. The primary mirror, S S, was fixed to the same frame R R R R. To fix the primary conductor exactly in the focal line of the mirror a template (Fig. 4) was employed. The distance separating the mirror from the primary conductor was made a little under half the length of the radius of curvature, to correct the edge rays. The frame was placed in the petroleum bath B B (Fig. 3). This arrangement has the advantage that for a given period the wave-length is smaller in petroleum than in air, and therefore the diffraction phenomena become considerably smaller at a given dimension of the mirror. The primary conductor has to be continually renewed, as after 100 discharges the platinum becomes useless. Throughout the research the management of the primary requires the greatest skill and attention, as its excitation depends in a very complicated manner on the supply of electricity.

Of the different arrangements which I had the opportunity of testing, the one shown in Fig. 1 proved to be the best. The size of the condenser C and of the water resistance W depends on the induction coil used. The size of the condenser C and of the water resistance W depend on the induction coil chosen and the regulation of its interrupter. For the one I used, which was fitted with a Desprez interrupter, and which, with eight accumulators, gave a maximum spark of 12cm., a Leyden jar consisting of a glass tube 1cm. in diameter and only 5cm. high was sufficient. A water column 5mm. diameter and 20cm. long served as a resistance.

From previous experiments with different primary conductors, I found the most suitable length of primary spark to be approximately proportional to the wave-length. For these discharge phenomena

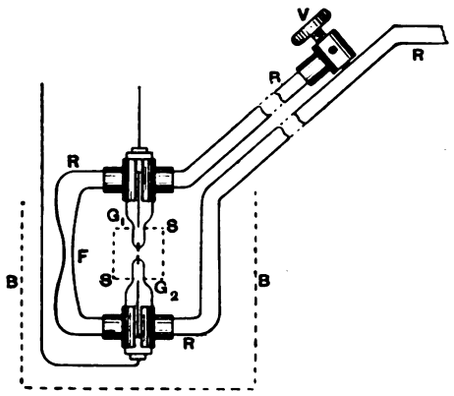

FIG. 3.

there is no quantitative connection between the length of the spark gap and dimensions of the conductor on the one hand, and the amount of radiated energy on the other. However, it may be taken that for double the wave-length the available energy is tenfold, making the determination considerably easier. A reduction of wave-length causes great difficulties, and the smallest apparatus with which I obtained results corresponded to a wave-length of 3mm., but the extremely small amount of energy radiated and the technical difficulties in producing the apparatus prevented further reduction of the wave-length.

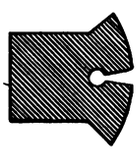

FIG. 4.

If for a given resonator a larger primary conductor is used, as described by Righi,[10] the excitation of the resonator increases. As, however, the main oscillation is a slower one, the large size of the mirror caused the diffraction phenomena to attain such a scale that the bundle of parallel rays became very ill-defined.

2.—*Resonators.*

In selecting a method of observation I compared bolometric and thermo-electric methods, and found the latter to be the most sensitive. This is explained in the following way: with decreasing dimensions the sensibility of the bolometer decreases, while that of the thermo-element remains constant.

The simplest way of making resonators with leading-in wires is to bend the ends of wire into the shape shown in Fig. 5 on an enlarged scale, and to fill up the loops with soft solder.[11]

The construction of the thermo-element from thin wires (about 0·01mm. diameter) appears to be more difficult than it really is. The *constantan* and iron wires sold in the market were about 0·025mm. in diameter,[12] and had to be thinned down in dilute tepid aqua regia till the required section was obtained. An ocular micrometer was used for measuring the wires. The wires[13] of the

[9] The extinction is in this case not a perfect one, as the galvanometer still shows a deflection of about one-fifth of the maximum, which can be explained by diffraction phenomena.

[10] A. Righi, *Memoria d. R. Accad. di Bologna*, p. 500, 1894.

[11] The thickness of the resonator must be less than one-third its length

[12] The wire was supplied by Hartmann and Braun, of Bockenheim, Frankfort-on-the-Main.

[13] The wires of each half of the loop must be very close to each other to get the circumference of the thermo-element rather small compared to the circumference of the resonators, as otherwise the natural period of vibration of the resonators would be much influenced.

Digitized by Google

thermo-element were then soldered to the resonators already placed in position on an ebonite plate. As the soldering iron used has to be very small, a gas jet should be arranged in it to keep it hot. As it is difficult, with these small dimensions, to get the thermo-element all right at once, it will be necessary to make several and select the best one. After soldering, the thermo-element will often not conduct current, and it will be necessary to connect the element to the secondary of an induction coil and close the primary for a moment. This creates a permanent metallic contact in the thermo-element. The resistance of such an element was found to be between 0·5 and 2 ohms. To increase the sensibility of the element I have with success cast it in a glass globe and exhausted the latter by means of a Sprengel mercury pump. The result was that the cooling down of the element became slower and the sensibility was considerably increased. The resonators were cast into the glass globe in such a position that they were in the focus of the glass surface, which was afterwards silvered over outside. Although this method has many experimental advantages, to keep in touch with the Hertz arrangement I also made experiments with theresonators in ordinary atmosphere.

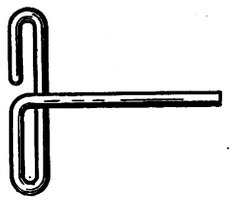

FIG. 5.

3.—*The Galvanometer.*

The unavoidable variations of the temperature of the thermo-element and the regular working of the primary conductor with currents of short duration necessitated a galvanometer of short oscillatory period ($\tau/2 = 3$ secs.). The galvanometer of Du Bois and Rubens,[14] with the special light-needle system and a length of magnet equal to 3mm., has proved to be most suitable. The external magnetic disturbances[15] were weakened about five times by replacing the glass cover by a cylinder of sheet-iron, about 2cm. thick.

4.—*Disturbing Influences.*

If the polarisation grating is so erected that no electrical vibrations can pass into the resonators, galvanometer deflections can still be created by disturbing secondary causes. It is of advantage to reduce these to one or two scale divisions. The magnetic forces generated by the induction coil and the conducting wires can be rendered harmless by giving the induction coil a suitable position, and intertwining the leads. The electrostatic influence of the leads of the primary conductor can create periodical charges in the circuit of the thermo-element, and cause deflections on the galvanometer. These disturbances can be to a certain extent avoided by interwinding the wires of the thermo-circuit, and by fixing a metallic mantle which is connected to earth, round the secondary mirror. Electrical oscillations of a long wave-length, if originated in the leads of the primary conductor (for instance, by side sparks), cause in some cases large galvanometer deflections. The thermal radiation of the primary conductor, which is reflected and refracted in the same way as the electrical oscillation, is so small that no heating of the thermo-element is perceptible.

5.—*The Observations.*

The slow alteration of zero, which is caused by the temperature variations of the room, is no disadvantage, since with its short swing $\left(\frac{\tau}{2} = 3 \text{ secs.}\right)$ the galvanometer deflection can easily be determined within 1 scale division. A considerable amount of uncertainty is experienced owing to the unsteadiness[16] of the primary spark. This can be reduced by taking the observations in a certain succession, and taking the mean. As an instance, the determination of the position of a diverted ray of the sulphur prism (P_g) may serve.

In Table I. the observed galvanometer deflections are given in scale divisions ; ψ^0 gives the positions of the secondary mirror on the circumference of the spectrometer. The arrows show the succession of the observations. During the series of experiments the primary spark was regulated four times.

If one assumes that the primary spark changes regularly, then the observed deflections can be reduced in the usual way to a constant activity of the primary spark. (Twenty scale divisions at $\psi^\circ = 150$.) Table II. gives the deflections so reduced.

In the same way the observations for the minimum position were taken. In Table III. the mean of two observations[17] for the sulphur prisms (P_g, and (P_k) are put together, and in Fig. 6 the same are graphically represented.

Table I.

150°	20	20	210°	20	20
155°	10	21	215°	23	17
160°	6	15	228°	18	13

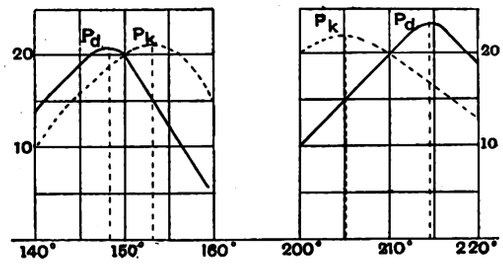

FIG. 6.

From Fig. 6 the maximum is obtained :—P_g, 148deg. and 214deg. P_k 153deg. and 205deg. From this the refractive index calculated ($\alpha = 25$deg.) $n_g = 2{\cdot}26$, $n_k = 2{\cdot}00$. All observations were made and reduced in the same way.

6. *The Sulphur Preparations.*—For the manipulation of the natural crystalline sulphur[18] some precautions are required, as the mineral will crack with the slight heating caused either by the touch of the fingers or by a saw. When the whole crystal can be used for a single prism, it can easily and quickly be shaped by simply rubbing the crystal on a piece of sandpaper. If, however, it is necessary to produce two prisms from one crystal, then it is advantageous to cut (with a fine saw) two cuts about 2mm. apart (alternately) in the given direction. The crystal will crack, of course, under the action of the saw, but the cracks will only take place in the rather thin intermediate layer. Further shaping is done by means of rubbing. By constantly using a goniometer, the angles may be made accurately within one degree.

In conclusion, it may be remarked that the small waves are suitable for an extensive use, as already with medium sized and at the same time optically perfect apparatus the diffraction phenomena can be neglected, and also for measurements, to which no objection can be made, easily obtained quantities of substances suffice. Hence it becomes possible to realise the simple conditions to which we have become used in optical experiments, also for the optical study of Hertzian waves.

[14] H. du Bois and H. Rubens, *Wied. Ann.*, Vol. XLVIII., p. 236, 1893. Supplied by Kayser and Schmidt, of Berlin.

[15] *See* G. Wiedmann, "Lehre von der Electr., Vol. III., p. 296 (1883).

[16] This unsteadiness seems to be the outcome of a fault in the primary conductors, and it shows itself in the quick formation of the primary spark.

[17] The second series of observations was made with a new primary conductor.

[18] The crystals were obtained from J. Böhm, mineralogist, Vienna.

CORRESPONDENCE.

THE HARGREAVES-BIRD ELECTROLYTIC CELL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your Journal of the 25th inst. you open an article on the Hargreaves-Bird cell as follows: "A paragraph which affords internal evidence of external inspiration has been lately perambulating." To which I retort: The article gives external evidence of internal spite, and complete evidence that you do not keep up to date with your continental contemporaries, or you would not need to report this at second hand. It first appeared in the *Elektrochemische Zeitschrift* under my own name as the contributor, and was given in response to the request of the editor; so perhaps you will retract the insinuation implied in your opening sentence. But if such a course puts you to any inconvenience you need not trouble about it; I am not at all particular. Again I read: "The figures quoted are of the usual misleading kind; an efficiency of 80 per cent. is claimed, by which the wise understand a reference solely to amperes; volts, we suppose, count for nothing." Then, if you did, you supposed wrong, and there is nothing in the communication to justify you in supposing anything of the kind. I gave all the factors, and took it for granted that I was addressing scientific readers. I did not presume to insult them by supposing that they could not work out the little equation

$$E=\frac{0{\cdot}8\times 2}{3{\cdot}4}=x$$

for themselves. Nor did I presume to occupy valuable space with such elementary matter. I am not in any way responsible for your not being able to understand it. I am too old a soldier to trouble myself much about such small shot as the above. Not a generation ago one "authority" says I *cannot* do it with less than 12 volts, and now you practically insinuate that I ought to do it with two. When I was at school I read the fable of the old man, his son, and his ass. *Verb. sap.*

You conclude your comments on my remarks, that there is a partial oxidation of the nascent hydrogen at the cathode, as follows: "As a matter of fact, we should require unusually good experimental evidence to induce us to believe that any oxidation whatever takes place." If you want the "experimental evidence" why don't you get it for yourself? You surely don't pretend to run a scientific paper without a few appliances for testing the truth of what appears in your pages, do you? Or do you suppose I am going to leave my work to hawk about "experimental evidence" for your satisfaction? For myself, it is enough to know—and it is not of the smallest importance whether *you* believe it or not—that alkali and "bleach" can be made for much less fuel than is needed in the Leblanc process, without the costly intervention of secondary reagents.—Yours, &c., JAMES HARGREAVES.

Farnworth, Widnes, October 26, 1895.

[We are glad that the writer of the above recognises the correctness of our reduction of the efficiency of the process with which his name is associated, from 80 to 50 per cent. or less. We think that, on reflection, he will agree with us that it scarcely falls within the province of a technical paper to investigate reactions inherently improbable.—ED. *E.*]

THE MAGNETIC FORCE IN THE PLANE OF A CIRCUIT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Russell's Paper in last week's *Electrician* is interesting, but I think it unnecessarily complicates the formula I have advocated for finding the force in the plane of a circuit, namely,

$$F=i\int\frac{d\theta}{r}.$$

Surely the simplest way of applying this is to plot a curve having $1/r$ and θ as cartesian co-ordinates, and integrate it. If r is measured in centimetres, θ in circular measure and i in C.G.S. units, the result is in C.G.S. electromagnetic units of force. Another way of expressing the result is

$F=i\times$(total angle subtended)$\times$(mean value of $1/r$),

the value of $d\theta$ being kept constant for every part of the curve; if $d\theta$ is varied proportionate weights have to be assigned to the values of $1/r$ in taking the mean.—Yours, &c.,

W. H. EVERETT.

THE SULLIVAN GALVANOMETER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As I am frequently asked how my Universal galvanometer behaves when used on board ship in a heavy sea, the following report dealing with that, as well as other points in the instrument, may possibly be of general interest. You would oblige me by kindly publishing the same:—

S.s. "Dacia," October 27, 1895, off Cadiz.

DEAR MR. SULLIVAN: I am very pleased to be able to send you a very satisfactory report on your marine galvanometer. All the way out we have had a very heavy sea, so I have been able to give it a pretty severe trial. In every way I find that it is very superior to the old ironclad Thomson marine galvanometer. Not only is the narrow coil just three times as sensitive as our Thomson, wound with 30,000 units, but, owing largely to the inertia of the coil, your instrument has been remarkably steady, while the Thomson suspension has been vibrating under the vibration due to the propeller to an extent which makes it very trying, and indeed almost impossible to read with any great degree of accuracy in a heavy sea. There is no creeping, and the spot seems to return to zero. This coil is, however, very sensitive, and as I have not taken quite the same pains in making the balance absolutely perfect as yet there is still a movement of about 5 to 10 divisions on either side of zero, when the ship is rolling very heavily, though only for moderate rolling there is little or no movement.

I have been very successful in balancing the wider coil and find both of them more easy to balance than the Thomson suspension, as the latter is affected by the magnetic dip when held in different positions, which has not to be taken into account when balancing your coil. It is a treat to watch the two suspensions at the same time and to see how perfectly your instrument keeps its zero. Even when perfectly balanced the Thomson suspension is displaced considerably from the scale zero, and is affected by the slightest vibration. When the ship changes its course, moreover, the zero changes and has constantly to be checked. This weak point alone gives a great deal of trouble, more especially when testing the insulation of short lengths of cable, which I am glad to find your instrument is free from. Owing to the ship rolling very heavily and carelessness in leaving the wide coil suspension insufficiently guarded on the table, while experimenting with the narrow coil, the wide coil suspending wires were both broken by sliding down the table against a key, so I very soon had occasion to try my 'prentice hand in re-suspending it. This was easily effected, with the result I have already mentioned. I can quite believe that the wide coil is more suited for excessive vibration, but though the "Dacia" is moderately affected in that way by the propeller, both your wide and narrow coils are exceedingly steady. The sensitiveness of your narrow and wide coils, as I am now using them, is represented by 360 and 205 divisions respectively, compared with 130 divisions obtained under the same conditions with the Thomson. . . .

I told you that I had not quite balanced your narrow coil suspension, but I have not the least doubt but that it will be perfectly immovable, like the wider coil, when I can find time to touch up the balancing again.

We are now entering Cadiz Harbour, and I am likely to be busy, so I must reserve a more careful and detailed report until I return to England, which, if the weather is suitable for our cable repairs, will be in about five weeks from present date, only I know you will be pleased to have another favourable report on your galvanometer.

Notwithstanding a sort of parental fondness which one has hitherto had for an only child, I am not sorry that our first has had his nose put out of joint at last, for my affection has often been sorely tried by the trouble the young rascal has given me. I have often marvelled at the patience an electrician has to exercise on board ship when following the erratic movements of his Thomson galvanometer, in order to obtain a correct insulation test, and I am sure many a one will cordially join with me in congratulating you on having turned out such a practical and satisfactory instrument.—I am, Yours faithfully, (Signed) JOHN RYMER-JONES.

P.S.—If it will be any advantage to make use of this letter you are perfectly at liberty to do so.

I may add that the above corroborates a previous report received from another independent quarter, but I must not further trench upon your space in this matter.—Yours, &c.,

29, Ladbroke-square, W., H. W. SULLIVAN.
November 12, 1895.

Royal Institution.—At the general monthly meeting of members held on the 4th inst, the managers reported that the late Mr. John Bell Sedgwick had bequeathed £300 to the Royal Institution in aid of the fund for the Promotion of Experimental Research at Low Temperatures. The special thanks of the members were returned to Sir Frederick Abel, Bart., for his donation of £50 to the Fund for the Promotion of Experimental Research at Low Temperatures.

LEGAL INTELLIGENCE.

South Staffordshire Tramways Company v. Ebbsmith and Another.

In the Court of Appeal on Monday, before the Master of the Rolls and Lord Justice Kay, the plaintiffs appealed from an order made by Mr. Justice Hawkins reversing an order of the Court under the Bankers' Books Evidence Act. The plaintiff Company alleged that the defendant Ebbsmith was the promoter and solicitor of a Company (the South Staffordshire and Birmingham District Steam Tramways Company, Limited) taken over by the plaintiff Company; that while Ebbsmith occupied that fiduciary position he formed a company called the Dickinson Tramway Appliance Company (Limited) which was a sham, being in fact Ebbsmith himself; that certain patents were bought up for small sums and assigned by Ebbsmith to the Dickinson Company; and that he then procured the plaintiff Company and their predecessor to purchase articles, the subject matter of the patents, and licences to use the patents, at exorbitant prices and without disclosing his interest in the patents. The plaintiffs claimed damages, an account of the defendant's profits, and a recission of the plaintiffs' contracts as to the patents. On the application of plaintiffs the Master made an order under the Bankers' Books Evidence Act that the plaintiffs should be at liberty to inspect the books of the Staffordshire Joint Stock Bank and their successors for the years 1885 to 1894, containing entries of the accounts of Ebbsmith in that name and in his former name of Joseph Smith, and of the Dickinson Company. Mr. Justice Hawkins reversed this order, and the plaintiffs now appealed. Affidavits were read by which it appeared that the signatories of the Memorandum of Association of the Dickinson Company were the defendant's partners and clerks, and that out of the 1,507 shares in that Company the defendant held 1,500. In 1889 these 1,500 shares were transferred by him to one of the signatories of the Memorandum of Association, who had previously held one share, and subsequently they were transferred to the Corporate Trust (Limited). A certified copy by the Bank of all entries in the defendant's account referring to amounts received by him from the South Staffordshire and Birmingham District Steam Tramways Company (Limited) and the Dickinson Company was put in.

The MASTER of the ROLLS, after hearing counsel, delivered the judgment of the Court, and said that the application was for liberty to inspect the accounts in the books of the Staffordshire Joint Stock Bank of the defendant Ebbsmith and also of the Dickinson Tramways Appliances Company. Taking the first of those two accounts, he had no doubt that the Court had jurisdiction to make the order applied for. The question was how the Court was to exercise that jurisdiction. The defendant had in this appeal sworn an affidavit that the items in his banking account which he had there given were the only items in it which were relevant to the issue in the action, and the Court must accept and act upon what had been thus sworn. The Court must refuse to order inspection before the trial, and would leave the judge at the trial to make any order that he might then think fit. As to the account of the Dickinson Company, no doubt the Court had jurisdiction to make the order asked for. But that jurisdiction must be exercised with the greatest caution, as the Dickinson Company were not parties to the present action. He thought that the person making such an application as this should show to the Court that there were at least strong reasons for expecting that the account in question contained items which would be damaging evidence against the other party to the action. Here it had not been made out that there were any such items in the banking account of the Dickinson Company as would be evidence against the defendant, and he could not see why there should be any items other than those which the plaintiff already knew of. Therefore it seemed to him that, if the order were made, the Court would merely be giving the plaintiff an opportunity to try and find if there were any items which might be useful to him. The appeal must therefore be dismissed.

Lord Justice KAY concurred.

Whiffin v. Crompton Electric Supply Company of Australia (Limited).

An application was recently made to Mr. Justice Stirling in this action that the appointment of the receiver and manager should be continued. It was explained that the business was now being carried on at a profit, and that there were prospects of its being sold either to another Company to be formed for the purpose, or to an existing English Company which might desire to extend its operations in Australia. His Lordship granted an extension for a fortnight.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

"THE WORK OF HERTZ."—By Dr. O. J. Lodge, with many origina illustrations, price 2s. 6d. nett, is now ready.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

TENDERS INVITED.—The Corporation of Durban require tenders for No. 40 cast-iron service boxes for connections from concentric mains, No. 120 cast-iron service boxes (or hand-holes) for house connections, No. 60 cast-iron junction boxes for arc lamps, No. 70 cast-iron manhole frames and covers, and No. 60 ornamental cast-iron arc-lamp pillars, 25ft. high. Conditions, &c., from the Consulting Engineer, Mr. W. H. Radford, Pelham-chambers, Nottingham, and tenders must be sent in to Messrs. Webster, Steel and Co., 5, East India-avenue, London, E.C., by the 27th instant. Further particulars appear in our advertisement columns.

——— The Swansea Corporation invite tenders for (1) the supply and erection of destructor and electricity supply station buildings; (2) for the erection of a chimney shaft, 150ft. high, with all necessary foundations and accessories; and (3) for the supply and erection of a dust destructor, including eight destructor furnaces and four water-tube boilers, with all necessary flues, dampers and accessories. Specifications, &c., can be obtained, after the 18th inst., from the Engineers (Messrs. Kincaid, Waller and Manville), 29, Great George-street, Westminster, S.W., and tenders, addressed to the Town Clerk (Mr. Jno. Thomas), The Guildhall, Swansea, must be in by 4 p.m. on Friday, December 6th. Further particulars appear in our advertisement columns.

——— The Metropolitan Asylums Board invite tenders for the execution of wiring and other work in connection with the electric light installation at the Brook Hospital and Ambulance Station, Shooter's Hill, S.E., from specification, drawings, &c., prepared by Prof. A. B. W. Kennedy, which can be obtained at the offices of the Board, Norfolk House, Norfolk-street, Strand, W.C. Tenders must be in by 11 a.m. on Monday next.

——— The Town Commissioners of Fermoy (co. Cork) invite tenders and schemes for the public and private lighting of the district by electricity. Tenders and schemes have to be sent in to Mr. P. J. Lane, Town clerk.

——— The Blackburn Corporation invite tenders for steam alternators and motor alternator, switchboard and engine room connections, street transformer chambers, transformers, &c. Tenders, addressed to the Town Clerk (Mr. Robert C. Fox), Town Hall, Blackburn, by the 30th inst.

——— The Windsor Corporation are inviting proposals for taking over and working their Provisional Order. Proposals to the Town Clerk, 4, Park-street, Windsor.

——— Tenders are invited for the manufacture and laying of a submarine telegraph cable from Puerto Montt to Punta Arenas, Chili. Conditions and specifications may be consulted at the Chilian Legation, 36, Victoria-street, S.W., and tenders must be sent in by December 5th next.

——— The Handsworth Urban District Council invite tenders for an installation of fire alarms to firemen's houses and telephonic calls to out-stations. Tenders must be delivered at the Council House, Handsworth, by the 26th inst.

——— The Midland Railway Company invite tenders for various stores for the year 1886. Included in the list are telegraph instruments, telegraph stay rods, bolts, &c., signal wires, malleable castings, &c. Tenders by the 19th instant to the Secretary, Mr. J. Williams, Derby.

——— The North-Eastern Railway Company invite tenders for various stores, including telegraph apparatus, telegraph wire and line stores, signal wire, castings, bolts, nuts, &c., for the six months ending June 30, 1896. Tenders must be delivered to the Secretary (Mr. C. N. Wilkinson), York, by the 26th inst.

——— The Cheshire Lines Committee invite tenders for the supply of telegraph materials, instruments, wire, &c., galvanised and zinc sheets, pulleys, bolts, screws and various other stores for the year 1896. Tenders by the 30th inst. to the Secretary (Mr. Glegge Thomas), Central Station, Liverpool.

——— The Belgian Minister of War invites tenders for the installation of the electric lighting in the New Military School, Brussels. Tenders to the Ministère de la Guerre, Brussels, by January 15th next.

——— The Hamburg Finance Deputation invite tenders for the supply and erection of an electric lighting plant in the Alte Allgemeine Krankenhaus. Tenders must be sent to the Finanz-Deputation, Hamburg, and are to be marked "No. 704."

——— The French Telegraph Administration invite tenders for the supply, in eight lots, of 46,280 impregnated wood posts. Applications to take part in the tendering are to be sent into the Direction Générale des Postes et Télégraphes, 103, Rue de Grenelle, Paris, by the 18th inst. The adjudication takes place on the 28th inst.

ELECTRIC LIGHTING SCHEMES INVITED.—The Battersea Vestry offer premiums of £50, £30 and £15 for the best three schemes, reports, designs and estimates for a system of electric lighting for the

Digitized by Google

parish. Schemes must be delivered to the Vestry Clerk (Mr. W. Marcus Wilkins) by December 12th next.

TENDERS ACCEPTED.—The Edinburgh Town Council received 16 tenders for the wiring of the Waverley Market, the amounts ranging from £459. 5s. to £991. 4s. The lowest tender, that of Messrs. James Milne and Son, has been accepted.

——— The tender of Thomas Parker (Limited), for the supply of two additional armatures at £224, has been accepted by the Walsall Town Council.

——— The Lowestoft Town Council have accepted the tender of Mr. J. G. Ling for putting the Town Hall in telephonic communication with the Sanatorium and stables for the sum of £49. 12s. 6d.

SALES BY AUCTION.—Messrs. Wheatley Kirk, Price and Goulty issue a preliminary notice *re* the sale by auction, at an early date, of the entire contents of the works premises at 45, Broadway, Walham Green, S.W., now in the occupation of Messrs. Russell and Co., who, as announced in a previous issue, have decided to give up business. Further particulars are given in our advertisement columns.

——— The Reading Electric Supply Company having completed their new electricity station, Messrs. Wheatley Kirk, Price and Goulty give preliminary notice of the piecemeal sale by public auction, at an early date, of the entire contents of the Company's old station, the Island, Reading, comprising engines, boilers, combined lighting sets, dynamos, &c. Further information is given in our advertisement columns.

PLANT FOR SALE.—Our advertisement columns contain particulars of a 2 H.P. generating plant, which Messrs. Henry Lea and Thornbery, Bennett's-hill, Birmingham, have for disposal.

BUSINESS FOR SALE.—Electrical engineers can obtain particulars from Messrs. Wheatley Kirk, Price and Goulty of a small electrical business for disposal in London, which would well suit a person with a small connection to add to the present business.

WORKS FOR SALE.—Particulars are given in our advertisement columns of some excellent branch works premises in the west end of London, adjoining a metropolitan station, which Messrs. Wheatley Kirk, Price and Goulty have for disposal.

CHANGE OF TELEPHONE NUMBER.—We regret to announce that we have received official intimation from the National Telephone Company that the telephone number of this Journal will in future be 6949, *vice* 2714. Please note. We are given to understand that our old telephone number will cease to exist, at any rate for some considerable time.

NEW PREMISES.—The Singer Manufacturing Company, makers of the well-known sewing machine, &c., have recently removed from their cramped premises in Cheapside to more extensive offices in St. Paul's Churchyard, E.C., where nearly 100 employés will have accommodation provided. The premises are lighted throughout by electricity, and the manufacturers' room, where a large number of special sewing machines for use in factories are exhibited, will be fitted for electric power, so that the machines can be readily shown at work.

APPOINTMENT.—The Leyton District Council have appointed Mr. A. J. Protheroe clerk of the works in connection with their electric lighting scheme.

POSTAL TELEGRAPH APPOINTMENTS.—Mr. E. Ashton, Superintending Engineer, West of Scotland District, has been appointed Superintending Engineer for the North Wales District, and Mr. D. M. Stewart, Assistant Superintending Engineer, has been appointed Superintending Engineer for the West of Scotland District.

ACCOUNTANCY.—Mr. T. Featherstone Smith, F.I.S., who was for some years with the General Electric Power and Traction Company, has established himself as an accountant and auditor at 15, Walbrook, London, E.C.

DIVIDENDS DUE.—Notice is given that a dividend of 2s. 2d. in the pound in the bankruptcy of Browning and Gardner, lately trading as electrical engineers, at Edinburgh, is payable on and after December 26th next, at the office of the liquidator, Mr. J. H. Buchanan, C.A., 8, York-place, Edinburgh.

BANKRUPTCY.—Mr. Registrar Linklater has approved a proposal by J. T. Todman, lately carrying on business as an electrician at 11, Queen Victoria-street, E.C., for the payment of 7s. 6d. in the £ on his debts. The creditors had previously agreed to the proposal.

Re J. C. HOWELL (LIMITED).—We have received the following :—

"The paragraph appearing in your edition of the 8th inst. has been brought to my notice. I beg to state that the liquidation has been brought about by the wish of the shareholders generally for the purpose of disposing of the business and assets of the Company. Under the liquidation the shareholders have consented to my disposing of the same to Mr. J. C. Howell as from the 1st inst., and negotiations are in progress for this purpose. The liabilities of the old Company will be discharged not by me but by the purchasers.—Yours faithfully, SIDNEY A. ISITT, Liquidator."

WINDING-UP PETITIONS.—A petition by a judgment creditor for the compulsory winding-up of the Mersey Rubber Company (Limited) was directed to stand over for six months by Mr. Justice Vaughan Williams on Wednesday last.

MESSRS. B. VERITY AND SONS.—Mr. H. R. Wood, recently in the employ of this firm, has been replaced in the position of London manager of the electrical accessory department by Mr. Russell, who was formerly second engineer at the Birmingham branch. The latter appointment is now filled by Mr. Allison, late of the P. and O. Steamship Company.

INCANDESCENT GAS BURNERS.—For some months past Charles-street, Cardiff, has been illuminated by incandescent gas burners, with the object of ascertaining if the lighting of side streets could be made by this system without increase in cost. Mr. Harpur, the borough engineer of Cardiff, has stated, in reply to inquiries, that the new burners are unequal to those formerly in use, and that the expenditure is precisely the same. There is no economy whatever, although the new burners are of the most improved type. Mr. Harpur does not think the burners at all suitable for street lighting, and a similar decision has been arrived at by the engineer of the Mile End Vestry. At Mile End it is stated that the mantle of the burners cannot stand the vibration of the street traffic or high winds.

INCREASE IN PRICES.—The advance in the price of Para rubber and in copper has led to a decision on the part of the leading manufacturers of electric cables and wires to revise the prices for these commodities. We mentioned in our last issue that the Telegraph Manufacturing Company had issued a circular to this effect to its customers, and similar circulars are now before us from the W. T. Henley's Telegraph Works Company, W. T. Glover and Co., and Messrs. Johnson and Phillips; and we understand that similar steps have been taken by the India Rubber Company, and that Messrs. Siemens Bros. and Co. have also put up prices to meet the increased cost of raw materials. An additional reason for this step is the fact that the leading manufacturers are full of orders, and are therefore all the less inclined to execute further contracts at the recent low figures, which, we understand, left but a small margin of profit. It has long been a complaint that acute competition has led to such a cutting of prices, especially in the heavy engineering departments, that the margin of profit in many important contracts has been all but *nil*. This is obviously a state of things that cannot continue indefinitely. If manufacturers cannot lower cost of manufacture they must try and raise prices.

AGENCY.—Messrs. Julius Harvey and Co., of Mansion House-chambers, London, E.C., have been appointed by Messrs. Musgrave Bros., hydraulic and general engineers, Leeds, as their representatives for London and district for the home and foreign trade.

DISCLAIMER.—In reference to the prospectus issued by the British Electrical Manufacturing and Engineering Company (Limited), reference to which has been made in our two latest issues, we have received from Messrs. Laing, Wharton and Down the following :—

"TO THE EDITOR OF THE ELECTRICIAN.

"SIR: Notices have appeared in your paper and elsewhere of a company styled the 'British Electrical Manufacturing and Engineering Company, Limited,' in the prospectus of which our name appears very prominently. As this prospectus has been framed and issued to the public without our knowledge or consent, we shall be obliged if you will allow us space to explain the circumstances, as far as we know them, and to correct an inaccuracy which is important to us, and may be misleading to the public.

"Finding that, for our own work exclusively, we could not advantageously run our brass finishing works, and as it is not part of the business of electrical engineers to conduct works of this kind for the *sale* of brass-work, we determined to dispose of the machinery and stock in this department. Accordingly, we had agreed to sell them to the gentleman who appears as the vendor to the 'British Electrical Manufacturing and Engineering Company (Limited).'

"We were expressly assured that no prospectus of any kind would be publicly issued, and as we feel that in the one which has come out, contrary to this assurance, much has been made of a concern which, so far as our share in it goes, is of very slender proportions, and our name is used, appearing so that the public would naturally think we had authorised what is said, we wish to disclaim all responsibility for the announcement.

"It is not true that we have undertaken to give the new Company all our work. The fact is that we have engaged to give them our orders for similar goods to those which we have heretofore ourselves made at our works, provided that they can do them as well as to workmanship, price and conditions as we can get them elsewhere.

"There is beyond these orders no goodwill in the department, and the expression that the Company has acquired the goodwill of our manufacturing department is very misleading.—Yours faithfully,

"LAING, WHARTON AND DOWN."

CATALOGUE.—We have had occasion to notice within the past few months a number of well-devised Electrical Trade Catalogues, and one certainly deserving of favourable mention is that just issued by the International Electric Company, of 55, Red Cross-street, Barbican, E.C. Comprising 200 large quarto pages, illustrated from first to last, and clearly printed, the book contains a mass of information concerning a large variety of electrical apparatus and accessories manufactured by Messrs. Mix and Genest (Limited), of Berlin, who are represented in this country by the International Electric Company. The various articles described and illustrated,

Digitized by Google

and concerning which full information is given, are too numerous to be specifically mentioned, but the trade can obtain copies of the book on application to the Company. The Catalogue bears evidence of being printed in Germany, but all the same it is very well printed, and is free from many of the errors so frequently associated with work done out of the country. By the way, no indication is given of its German origin. Altogether the book contains about 900 illustrations, and includes 66 diagrams for bell and telephone installation work. A copious index facilitates reference.

ASHTON-ON-MERSEY.—At the last meeting of the District Council it was decided to support the Altrincham Electric Supply Company's application to the Board of Trade for a Provisional Order.

BANGOR (Co. DOWN).—The Town Commissioners have decided to apply for a Provisional Order.

BARTON REGIS.—At the last meeting of the Board of Guardians a letter was read from the Stapleton District Council inquiring if, in the event of electricity works being established by the Council, they would consider the question of lighting the workhouse electrically. It was decided to reply that the Guardians could not at present incur such expenditure.

BROMLEY.—At the last meeting of the District Council a communication was received from the Board of Trade inquiring what steps had been taken to comply with the conditions of their Provisional Electric Lighting Order.

BURY ST. EDMUNDS.—At the meeting of the Town Council on Tuesday last the Electric Light Committee were empowered to engage an electrical expert to prepare a report on the electric lighting question, at a cost not exceeding 50 guineas.

BUXTON.—At the last meeting of the District Council Mr. Cooper referred to the fact that the Council's Provisional Electric Lighting Order would expire in June next, and urged the members to take the electric lighting question into serious consideration. It was decided to call the Electric Lighting Committee together with a view to taking some concerted action in the matter.

CHELSEA (LONDON, S.W.).—At the last meeting of the Board of Guardians a letter was received from the Chelsea Electricity Supply Company, stating that their sliding scale for electric current supplied to the workhouse premises would be 5d. per unit, 1d. less than the usual rate, and a further reduction when warranted by increased consumption. It was stated that specifications were being prepared for the wiring of the new workhouse buildings in Sydney-street for the electric light.

CHURCH LIGHTING.—The Dean and Chapter of Ripon Cathedral intend to make some experiments in electric lighting, and accordingly Messrs. G. Harrison and Co. have been instructed to put in a small installation for lighting the choir. The contractors have decided to use Brockie-Pell arcs.

COMMERCIAL EDUCATION.—A conference of the leading teaching and examining bodies of the kingdom and of representative county councils which are in a position, under the County Councils' Act, to contribute funds for the purpose of technical instruction, was held under the auspices of the London Chamber of Commerce, at Drapers' Hall, London, E.C., on Tuesday afternoon, under the presidency of Sir A. K. Rollitt, D.C.L., M.P. The teaching bodies represented and the delegates present at the meeting included most of the best known scholastic establishments and masters, and the Commercial Education Committee of the London Chamber of Commerce was represented by, amongst others, the following: Sir A. K. Rollitt, Sir Philip Magnus, Mr. A. T. Pollard (Head Master, City of London School), Dr. Scott (Head Master, Parmiter's School), &c. A resolution was agreed to approving the principle of the co-ordination and simplification of the present system of examinations in commercial subjects, and the matter was referred to the Committee to consider details and formulate a scheme to carry this resolution into effect.

COVENTRY.—Electric current was available for the first time on Saturday last for private lighting in most of the principal thoroughfares of this town. The proposed formal opening ceremony has been abandoned.

DERBY.—The Town Council intend to apply to the Local Government Board for sanction to borrow £4,146. 3s. 11d. The sum is required for extras, &c., in connection with their electric light works.

DOVER.—At Monday's sitting of the Town Council it was decided to apply to the Board of Trade for the necessary powers to enable the Council to construct electric tramways throughout the borough.

DUNDEE.—At the meeting of the Guildry last week the representatives of the Harbour Trustees presented their report of the work done during the past year. After the reading of the report, Mr. R. Taylor suggested that an electric tramway should be put down along their harbour for the use of workmen and merchants going and returning from Broughty Ferry. If the electrical area were extended towards the gas works it would be for the Trustees to consider the laying down of an electric tramway, as electricity would undoubtedly prove the best motive power for the purpose. Mr. A. Leitch said they would be glad to see the Gas Committee of the Corporation extending the electric lighting area so as to embrace the harbour. Many harbours were now being lighted electrically, and their own Harbour Trustees were considering at the present time whether they should light the buoys in the river by that means. If they decided to do so, they would probably put down generating plant of their own, and this would not be in the interest of the community; he would much prefer to see the Corporation's electric lighting area extended and the trustees obtain their current, both for lighting and power purposes, from the Corporation. Mr. Brownlee pointed out that if the trustees desired to be connected up to the electric lighting area that could be done at once. With regard to the tramway there was no doubt that the want of easy access to the east end of the harbour works was badly felt. He was, however, not quite sure that the electric tramway was the best means by which this want could be met, as it would necessitate the erection of a supply station capable of producing a much higher voltage than that required to light the city.

ECCLES.—The Town Council at their meeting on Monday last referred the matter of proceeding with their electric lighting scheme to the newly-constituted Electric Lighting Committee.

EDINBURGH.—At the last meeting of City Council, the Electric Lighting Committee reported that the demand for electric current had been so great that their present generating plant was already taxed to its utmost capacity. They were at present supplying current to an equivalent of 38,000 8-c.p. lamps connected, and they had several customers waiting to be connected up. The capacity of their present plant was an equivalent of 40,000 8-c.p. lamps, and they therefore recommended that another engine and dynamo be added to the plant. The report was agreed to without discussion.

GLOUCESTER.—At a special meeting of the City Council on Tuesday last it was decided to apply for a Provisional Order.

GREAT YARMOUTH.—The electric light is making very satisfactory progress in this town. At the last meeting of the Council the Electric Lighting Committee reported that there was a net profit for the month of October of about £20, and that there were additional applications for 302 16 c.p. lamps, which would bring the number of lamps up to 5,780. It was also decided to put in additional plant at the generating station, and the question of extending the mains to Southtown and Gorleston was deferred for the present.

HARWICH.—The Town and Village Electric Light and Power Company have agreed to take over the Harwich Provisional Order.

HORSELESS CARRIAGES.—At the last meeting of the Staffordshire County Council an interesting discussion arose on the extent of the Council's bye-laws, and the meaning of certain terms. The definition of the term "vehicle" is set forth as "any carriage, cart, waggon, dray, or vehicle of any description drawn or propelled by animal or steam or electric power, but does not mean or include any bicycle, tricycle, velocipede, or other similar machine." After some discussion, it was decided to add the words "unless driven by steam, electrical, or other mechanical power."

HUDDERSFIELD.—At the last meeting of the Town Council it was reported that electric current was at present being supplied to an equivalent of 18,500 c.p. lamps, and that good progress was being made with the work of extending the mains to Lindley, where several large customers were impatiently awaiting the advent of the electric light. It was also stated that for some time past the Electric Lighting Committee had been endeavouring to create a demand for current for motive power, cooking and heating purposes, and thus obtain a day load for their machinery. Although the Committee have already obtained a certain measure of success in this department of their undertaking, in order to further encourage the use of electric current the Committee recently reduced the price of current during the daytime to 2½d. per unit, and for the convenience of those desirous of trying electrical appliances arrangements were made for hiring them on very reasonable terms. It is stated that the cost of generating current has been reduced in a most satisfactory manner, owing to the increased demand and to economies effected.

INSTITUTION OF CIVIL ENGINEERS.—The members of this Institution attended the opening meeting on Tuesday at their new premises which has been built from the designs of Mr. Charles Barry. In addition to the old block in Great George-street, Westminster, S.W., occupied by the Institution, the next-door premises have been included, which gives greatly increased room and accommodation. The contract for the buildings was given to Messrs. Mowlem and Co., Westminster, for the sum of £41,000.

IPSWICH.—At a recent meeting of the Paving and Lighting Committee a representative from the County of London and Brush Provincial Company attended for the purpose of ascertaining whether the Council would oppose the Company's proposed application for a Provisional Order, and if any arrangement could be

Digitized by Google

come to with the Council in the matter. After some conversation it was decided that the Company should submit particulars of their proposed scheme as soon as possible. It will be remembered that the Town Council recently decided not to apply for a Provisional Order.

KETTERING.—A special meeting of the Town Council was held yesterday (Thursday) for the purpose of discussing the Lighting Committee's report on the electric light question.

LAMBETH (LONDON, S.E.).—The local journals of this district are gradually coming round to the view that the Vestry would be well advised in carrying out an electric lighting scheme for the district, which is one of the largest in the metropolis.

LECTURES.—The subject of "Horseless Vehicles" has now entered the lecture stage. Mr. G. C. Marks on Wednesday delivered a lecture at the opening meeting of the Birmingham Municipal School Engineering Society on this subject, before a crowded audience. Mr. Marks, by the aid of an excellent series of lantern slides, described many attempts at the invention of a successful horseless vehicle worked by electricity, steam, oil, manual, or pedal power, from the time of the Frenchman, Nicholas Joséph Cugnot, in 1729, down to the present time. Mr. Marks strongly advocated a change in the law as to the classification of bicycles and tricycles driven by electricity or other motive power, and the Chairman, Councillor Martineau, announced his intention of bringing the matter prominently before the Birmingham Corporation.——At Newcastle on Monday the Hon. C. A. Parsons delivered a lecture to the students of the Durham College of Science "On the Application of Electricity to the Transmission and Storage of Power," "Production of Light," "The Melting of Refractory Substances," &c.——Mr. W. B. Sayers delivered an interesting lecture on "Electro-Magnetic Motion" in the U. P. Hall, Bearsden, Glasgow, on Monday last.

LIMERICK.—At the meeting of the Town Council last week it was decided to appoint a committee to consider the various details in connection with the introduction of the electric light, and report to the Corporation on the replies to be sent to the queries from the Board of Trade. The Committee were also empowered to expend £50 in obtaining the opinion of an electrical expert.

LIVERPOOL.—The Markets Committee of the City Council are to consider the question of lighting the market electrically. At the last meeting of the Council, Ald. Walker, the new chairman of the Committee said he thought they should make the first experiment in St. John's Market. At present they had to clean this market once every three years at a cost of nearly £800, and if the electric light were installed it would require cleaning only once in six years.

LONDON COUNTY COUNCIL.—At the meeting on Tuesday the Finance Committee reported the completion of the loan of £5,150 to the Islington Vestry for the purchase of land for electric lighting station. The Fire Brigade Committee reported that the chief officer had asked that the system of telephonic apparatus at the chief office might be made uniform with that at the superintendent's offices. The Post Office had intimated that the charge for making the necessary alterations and providing and maintaining the necessary new switching apparatus was estimated at £67. 10s. per annum, subject to the same stipulations as were agreed to when similar apparatus was fitted at the superintendent's station. Annual charges of £9 would cease, and the net annual charge, therefore, would be £58. 10s. They recommended that the necessary expenditure be authorised, and this was agreed to. Mr. Emden has given notice of the following motion:—"That it be referred to the Highways Committee to consider and report without delay on the expediency of the Council applying to Parliament for power for the Council and the local authorities to construct subways under the streets of London for the reception of tubes and wires of the gas, water, electric and other companies, and to charge rents for the same."

LOWESTOFT.—At the last meeting of the Town Council a letter was read from Mr. T. W. Baker relative to obtaining a Provisional Electric Lighting Order, and it was decided to reply that the Council did not at present intend to apply for an Order.

MANCHESTER.—The City Council on Wednesday last authorised the promotion of a local Bill in the next Session of Parliament for various objects, amongst which is the acquisition of the undertaking of the local Tramways Company. In the Bill the Council reserve the right to adopt an electrical or other mechanical system of traction.

MILL LIGHTING.—Some time ago a portion of the Manningham mills was lighted electrically, and the installation has proved so satisfactory that the proprietors (Messrs. Lister and Co.) recently decided to make considerable extensions. Since 1889 about 2,000 16 c.p. incandescents and 40 arcs of 1,000 c.p. each have been employed, but this number will now be augmented by 2,700 16 c.p. lamps. It is stated that when the extensions are completed this will be one of the largest private lighting plants in the kingdom, consisting of an equivalent of about 8,000 16 c.p. lights. The whole of the work has been carried out by Messrs. T. Preece and Co., of Bradford.

NESTON (CHESHIRE).—A report by Mr. T. H. Marsh, electrical engineer, on the question of the advisability of lighting this district electrically was recently presented to the Lighting Committee of the District Council. Complaints have for some time past been made as to the high price and deficiency in illuminating power of the gas supplied by the local Company. Mr. Marsh reports that, after careful consideration, the general conditions are favourable to the establishment of remunerative electricity works, and he recommends the Council to adopt a high-tension alternating-current system. The initial expenditure is estimated at £6,000, the working expenses at £463. 6s. 8d., and the sinking fund and interest at £360 per annum, while the probable income is estimated at £1,551. 5s. This report was discussed at a meeting of ratepayers on Wednesday last.

NEWCASTLE-ON-TYNE.—At a special meeting of the City Council on Saturday the formal resolution in favour of the promotion of their Tramway and Improvement Bill in the next session of Parliament was passed. It will be recollected that the Council recently decided to obtain powers to work the tramways (except the Westgate-road, Arthur's Hill, Elswick-road, Scotswood-road and Byker sections) by electricity or other motive power.

NEWPORT (MON.).—Some time ago the Town Council hired some spare electrical plant from Messrs. John Fowler and Co. (Leeds), with the option of purchase within three months. At the last meeting of the Council the Parliamentary and Improvement Committee recommended that the spare plant be purchased for the sum of £1,000, this amount to include a sum which had accrued in respect of hire, subject to the sanction of the Local Government Board being obtained thereto. The recommendation was adopted.

PAISLEY.—The Town Council intend to light the Town Hall and Museum electrically. Dr. J. T. Bottomley has been appointed consulting engineer for the work at a fee of 100 guineas.

PLYMOUTH.—At the last meeting of the Town Council it was decided to form an Electric Lighting Committee. The electric lighting question has hitherto been in the hands of a small sub-committee.

PEMBROKE (DUBLIN).—At their meeting on Tuesday last the Town Commissioners decided to apply for a Provisional Order.

PROVISIONAL ORDERS.—The Corporations of Bath, Godalming, Middleton and Wells give the usual notice of their intention to apply to the Board of Trade on or before December 21st next for Provisional Orders under the Electric Lighting Acts 1882 and 1888.

RADCLIFFE (LANCS.).—At the meeting of the District Council on Tuesday it was decided to form a special Electric Lighting Committee to carry out the provisions of the Radcliffe Provisional Order.

ROTHERHAM.—The Town Council have appointed a Committee to consider and report upon the questions of lighting the town electrically and of constructing electric tramways.

RUNCORN.—At the last meeting of the District Council the Electric Lighting Committee recommended that application be made to the Board of Trade for a Provisional Order. The Rev. Dr. Gastaldi, in moving the adoption of the minutes, said they had ascertained that an electric light installation, capable of supplying current to an equivalent of 2,000 8 c.p. lamps, would cost about £11,000. The interest and the sinking fund would amount to about £750 per annum, but they would still save £200 a year if they adopted electric lighting. After considerable discussion an amendment that the application for a Provisional Order should be deferred until the Committee showed that there was a probability of the powers being taken advantage of was carried.

SALE.—At the last meeting of the District Council it was resolved to apply to the Board of Trade for a Provisional Electric Lighting Order, and to oppose the application of the Altrincham Electric Supply Company (Limited).

SANDWICH.—Negotiations are in progress for the construction of nearly two miles of tramways in this town.

SHEFFIELD.—At the annual meeting of the School of Art on Monday last the report stated that the Council had carefully considered the respective merits of incandescent gas lighting and electric lighting, more particularly in regard to the best means of avoiding the excessive heat and vitiated air produced by the present gas supply when classes were in full work, and ultimately it was decided to adopt the electric light, as this was considered to be the best and most efficient mode of illumination. The installation was carried out during the summer vacation at a cost of £200.

SOFIA (BULGARIA).—An electricity generating station is to be erected next year in this town for supplying current for lighting and traction purposes. It is proposed to utilise water power in connection with the scheme.

SPAIN.—Tenders have recently been invited for the establishment of a central station in the town of Piloña (Orense). A company is in course of formation at Tarrasa to establish and operate a central station in the town. An electric lighthouse is approach-

Digitized by Google

ing completion at Cabo Villano (Galicia). The little town of Llanes is now lighted by electricity.

STAPLETON.—The District Council has instructed the Electric Lighting Committee to visit Taunton and Bath electricity stations, with a view of obtaining information to assist the Council in its proposed adoption of an electric lighting scheme for Stapleton.

ST. MARNOCH'S (DUBLIN).—The contract for the electric lighting and pumping plant for St. Marnoch's, co. Dublin, to the specification of Mr. Morgan Williams, C.E., has been placed with Messrs. Edmundson (Limited), of Dublin. Motive power will be derived from oil engines.

SUICIDE.—A sad tragedy was enacted at Ealing on Tuesday, when Mr. G. E. Hartmans, aged 28, an electrical engineer, committed suicide while suffering from delirium produced by typhoid fever. Mr. Hartmans was in charge of a nurse, but broke away from her control and secured the revolver with which the fatal act was accomplished. Mr. Hartmans had recently been studying heavily to pass his examination for a captaincy in the Essex Rifle Volunteers, in which he held a lieutenant's commission.

SWANSEA.—The electric lighting scheme prepared by and presented to the Swansea Corporation by Mr. E. Manville having been adversely criticised by an anonymous correspondent of the *South Wales Daily Post*, Mr. Manville, in the issue of the 8th inst., in a lengthy letter to the editor of that journal, replies fully to the adverse criticism of the anonymous correspondent, who is described as "one of the foremost electrical experts in the Kingdom."

TAUNTON.—At the meeting of the Town Council on Tuesday the electrical engineer stated that the demand for electric current was steadily increasing. They had connected an additional 140 16 c.p. lamps during the quarter, and the maximum load on the private lighting circuits was about 20 per cent. greater than it was in the corresponding quarter last year.

TORQUAY.—At the meeting of the Town Council on Tuesday last the Electric Lighting Committee's report, which recommended that steps be taken to establish electricity works in Torquay, and that application be made to the Local Government Board for sanction to borrow £18,000 for the purpose, was discussed. Mr. Kerswill strongly advised the Council to adopt the report, and stated that their consulting engineer, Mr. W. H. Trentham, had slightly modified the details of his suggested scheme. The probable income was now put at £3,600, while the annual expenses and interest were estimated to amount to £2,292, leaving an estimated net profit of £928. A long discussion ensued, and it was finally decided to refer the matter to a Committee of the whole Council.

TRALEE (IRELAND).—The Town Commissioners are considering the question of lighting the town electrically.

TRAIN LIGHTING.—A recent issue of the *Hawke's Bay Courier* contains an account of a trial trip of an express train on the Manawatu Railway. It appears that the railway company have decided to light their express trains by electricity, and a trial run was made to Porirua, about 14 miles from Wellington. Several carriages were lighted, power being obtained from a dynamo placed under the floor of a luggage van, and worked by a belt from the wheel of the car, which also contained a battery of accumulators. After a portion of the journey had been made the kerosene lamps were extinguished and the electric light switched on. The improvement in the light was, of course, at once apparent, and it is stated, so successful was the experiment, that all the principal express trains on the line will in future be lighted electrically. Mr. Turnbull, electrical engineer, had charge of the experimental installation. ——Electrically-lighted cars are no novelty on the London, Brighton and South Coast Railway, and the pullman service of trains, which the Company recently established between Victoria and Brighton, is also fitted up for the electric light.

TYNESIDE.—It is stated that orders recently received for electrical plant and apparatus by electrical engineers and contractors having works premises on the Tyne have been very numerous of late, especially for ship lighting for the new Government cruisers and for vessels ordered by foreign governments and shipping companies.

WEYBRIDGE.—The District Council have appointed a committee to confer with the Weybridge Electric Light Company as to the transfer of their Provisional Order to the Council.

WOKING.—Another meeting of ratepayers in the St. John's Ward was held last week for the purpose of discussing the lighting question, and a resolution in favour of the introduction of the electric light was ultimately passed.

YORK.—At the last meeting of the City Council, the Streets and Buildings Committee reported that Mr. W. H. Preece, C.B., who had been invited to prepare and submit a report on the best system of electric lighting for the city, had written stating that in consequence of the terms of his appointment as chief engineer to the Post Office he was unable to undertake the work. It was therefore resolved to approach Prof. A. B. W. Kennedy on the subject.

COMPANIES' MEETINGS AND REPORTS.

Western and Brazilian Telegraph Company (Limited).

The thirtieth ordinary general meeting of this Company was held at Winchester House, Old Broad-street, E.C., yesterday (Thursday), under the presidency of Mr. W. S. Andrews.

The SECRETARY (Mr. R. M. Cunningham) read the notice calling the meeting and the minutes of the last meeting, which were confirmed as correct, and the report of the Directors was taken as read.

The CHAIRMAN: Gentlemen, I have now to tell you that the result of the half-year's working, on the revenue account to June last, has not been unsatisfactory. Our total take amounted to £84,936, against £77,603 for the corresponding period of the previous year, which reveals an increase of £7,333. Exchange during the half-year averaged 9⅝, against 9½ in the corresponding period of 1894—a very small difference, and one which practically does not affect the figures. There was a slight increase in the number of the words transmitted, although not so large as we have been accustomed to of late, both as respects the internal traffic and the international traffic. The internal traffic increase was larger than the international. The revenue we derive from the new lines to the West Coast, the Pacific and European Company, continued to develop satisfactorily, and, as a fact, they have given us the larger part of this increase; and the receipts from this source, I am pleased to say, affecting the Platino Company and the Company—for we get back from the Platino Company in dividends pretty much what they receive as dividend—promises to continue a very satisfactory rate of progress. If you remember, we estimated that we should receive £5,000 from that source for nine months and a few days to December, 1894. We at the same time rather led you to anticipate that the amount might be increased, and it is satisfactory to state that it was increased, and that the traffic continued to progress. Now, looking at the fact that we had reductions during the half-year under review, the net outcome, I think, is rather encouraging than otherwise; in fact, the point which has been brought before you so often—namely, that of the exchange—really continues to rule the question. If we had a satisfactory exchange we should have little to complain of, and should be a fairly prosperous concern. I hope we may one day be so. With regard to the expenses, they amounted for the half-year to £37,891, against £37,953. There is a small reduction there of £61. Under Abstract A there are seven items showing increases and six exhibiting decreases, and those items are composed of figures affecting very different subjects. The largest item is that of £493 for staff abroad—namely, increased staff and promotions under old agreements of members of the staff who have been with us for a considerable number of years. Together the effect of those features is an increase of £493. As to Abstract A, a still further decrease is shown under the heading of shipping of £581, which is satisfactory. Under Abstract C—the expenses in London—there is a slight increase of £113, and there again this is composed of some ten items, increases and decreases, and the whole thing is so small that it is not worth troubling you with. The upshot of all that is that we carry down £47,045, which, with £2,846 brought over from the previous half-year, leaves us with £49,891. From this has to be deducted £11,223 for debenture interest, and we have placed £5,000 to reserve and £7,876 to debenture redemption. The debenture redemption fund, I may say, has been allowed to run down somewhat, and we have therefore had to make it up. We have also had to pay £1,729 for income tax. Deducting these amounts we are left with £24,061, which now has to be dealt with by the shareholders. This sum enables us to recommend a dividend of 3s. 9d. per share on the Ordinary shares of the Company, or at the rate of 2½ per cent. per annum, against 3s. per share and 2 per cent. per annum for the corresponding period of 1894, and we carry forward £5,803 for the benefit of the current half-year. I should have liked the result to be better, but still, on the whole, it is not so bad. I have now disposed of the question of revenue and expenditure. There will be curiosity in the minds of some of you, naturally, to know the position of the purchase question. Well, that remains pretty much what it was; in fact, the authority which the Government have secured for the purchase of our lines, if not exercised, would have expired in the ordinary course of events this year. The Government, however, who seem to be willing buyers, have applied to the Legislative Assembly for a prolongation of their power to purchase. The Legislative Assembly has approved of the Bill to that effect, and that will, I imagine, be speedily passed by the Senate in the ordinary course of things, so that the Government will continue the power to purchase which it has not up to the present time—I presume on account of financial and political considerations—found it expedient to exercise. Meanwhile, things have not been standing still. A new company has been formed to connect the important ports along the great Amazon river by a submarine cable with the systems of the Government and of this Company at Para. We speak of laying a cable in the River Amazon, but the river more resembles an inland sea than a river, for it varies in width between five miles and 10 miles, although it is generally the larger figure; and during the flood season the river is pretty quiet because the country around lies very low and is very flat, and the water disperses itself all over it. You then have a river, if you can call it so, about 30 miles wide. I am pleased to say that this line of communication is being rapidly completed, as we have been informed by the contractors, and all the apparatus and necessary preparations are being pushed forward vigorously. When this work is completed, which is expected to be accomplished in the early spring, it will, we hope, prove a valuable feeder to this Company. The Government and the mercantile classes of Brazil have for a very long time been desirous of seeing this work completed, and we are informed that the local authorities—the Governors and so on—have rendered every

Digitized by Google

assistance they could in furthering the operations of the gentlemen who went out to supervise the laying of the line and the establishment of the stations. I now have to approach a subject which I should have preferred to leave untouched, only that I am anxious that no incorrect impression should find a lodgement in the minds of the shareholders. No doubt, the shareholders have seen the speech which was made by the Chairman of the Brazilian Submarine Telegraph Company at the annual general meeting of that Company, and the discussions in the newspapers in reference to the laying of a submarine cable from St. Vincent, *via* Ascension, and the island—the very much disputed island—of Trinidad to the River Plate. Well now, gentlemen, as I believe many of you are aware, the Brazilian Submarine Company have no lot or part in laying such a cable during the existence of the Western and Brazilian Company, because it would be contrary to subsisting agreements, and because also it would be contrary to the interests of this Company, which would therefore insist on subsisting agreements being carried out. Under this agreement, which is at the present time rather an ancient document, the purchase of the Western and Brazilian Company's lines by the Government of Brazil is foreseen, and, more than that, it is provided for. If the purchase were carried out the agreement, under its own provisions, would, *ipso facto*, cease and determine, and the Brazilian Submarine Company then, of course, as far as this agreement goes, would be free to do as they thought fit. At present, however, we say they are not free to do as they think fit, if such action is contrary to the agreements with this Company. But looking at the provisions of this agreement the notice of the Government to purchase the Western lines was at the least not an improbable eventuality, and I do not think it is too much to say that this question must have entered into the calculations of the Brazilian Submarine Company. Where, therefore, there was such a probable contingency as this being taken into consideration, need there be any surprise or excitement? It is a sort of thing we were all of us led to expect might happen—both we and the Brazilian Submarine Company. The Government of a great country like Brazil, with such an immeasurable future, would, there is no reasonable doubt whatever, in the interests of its own trade and commerce, treat the Brazilian Submarine Company, and all interests concerned, with perfect impartiality, and would doubtless only be guided by two considerations—the justice of the case and the advantage of its own mercantile public. Now, whatever may be said, there is no doubt that the efficiency and the good service of the Brazilian Submarine Company are indisputable, and that from this important point of view the Company would be always capable of holding its own. The Brazilian Submarine Company appear to have thought that the Western Company has not acted in a friendly spirit towards it out in Brazil—I suppose on account of the purchase, which all of us expected. Our instructions have been the direct opposite to anything of the sort. We have always endeavoured, under all circumstances, while protecting the rights of our Company, to maintain the most friendly relations between the two Companies, and we continue, and we shall continue, to act in this direction. It goes without saying that our interests—I mean those of the two Companies—are so far identical that any other policy would be fatuous. I cannot imagine anyone supposing that we could be capable of any other policy—it would be cutting our own throats. We must naturally go on acting and working as if we were a continuing Company; that appears to us the only businesslike course. We think the Companies—not restricting myself to one Company—may look forward with confidence to the conclusion that, whether the Western lines be purchased or not, we are bound to take both alternatives into our consideration provided we do our best to serve the interests and earn the approval of the Brazilian Government and mercantile public by prudent and conciliatory action; we shall be treated accordingly, and may both participate in the great future reserved for that immense territory, which is now, I may say, by the enterprise and far-reaching prevision of its Government, linking up its distant Amazonian possessions through Para with the general network of the telegraphic intercourse of the world. This and other measures of development should have the happiest influence upon the rapidly increasing progress of the country, for population, as a rule, follows in the wake of enterprise. That concludes my observations with respect to this important matter. I may add that with respect to the Company's ships, I have an announcement to make which is rather agreeable—that negotiations are going on with reference to the purchase of one of these ships—subject, of course, to survey, and we have every reason to believe that those negotiations will result in our being enabled to strike off one of these ships from our accounts. I now beg to propose—

"*That the report and accounts to June 30, 1895, now submitted, be and the same are hereby approved and adopted, and that a dividend for the half-year, free of income tax, at the rate of 2½ per cent. per annum, be, and is hereby declared, payable on the 15th inst.*"

Lord RICHARD H. BROWNE seconded the motion.

Mr. DYETT called attention to the following passage in the report:—"The Directors have to notify that the conversion of ordinary shares into Preferred Ordinary and Deferred Ordinary shares will be suspended on and after January 1, 1896, until further notice." He wished to know whether the Chairman could give them an idea whether this would affect them in any way. He afterwards called attention to the stationery account—£68 in Abstract C, and £979 in Abstract A, or over £1,000 for the half-year, and therefore, he said, over £2,000 a year. He thought that that was too much. He also referred to the unclaimed dividends.

The CHAIRMAN, in reply, said: With respect to the shares, Preferred and Deferred, which the honourable proprietor asks a question upon, the reason the conversion is temporarily in abeyance is the difference that would appear if the conversion went on and the dividends were not fully paid. Some shares would be transferred with a certain amount of arrears on them and others with other amounts of arrears. It was in order to avoid the confusion of these accounts when that might arise that it was decided to suspend the conversion, but it does not affect the status of the shareholders.

Mr. FRY said he must protest against the Chairman's statement in this matter. The answer was always the same, but they had always paid their preferred interest.

The CHAIRMAN: This measure was adopted at the suggestion of the Stock Exchange, so I think you will admit that, on the whole, it comes backed up with considerable authority. We do not want it—it makes not the slightest difference to us. The honourable proprietor also asks certain questions with respect to the stationery, and he would very naturally double the half-year's expenditure on that account, but if you take the December half-year and compare it with this half-year, you will find the amount is not doubled. This half-year the expenditure is a little under £1,000, while last half-year it was only £420. With respect, however, to the stationery, as with respect to other things, there is, of course, consumption going on at all our stations. You cannot deal with hundreds and thousands of messages and all kinds of documents which must be used in connection with the work without spending money on stationery. The honourable proprietor is right in drawing attention to it in this way, but he may think that we are not as careful of the expenditure as we might be. However, I do not think there is much expenditure in this Company without its being very carefully looked after. As to the question of unclaimed dividends, we should be delighted if everyone would come and claim the dividends to which they are entitled, but, owing to trusteeships and other causes, these things are allowed by the shareholders to accumulate.

Mr. DYETT thought that some information should be given to those to whom the dividends belonged.

The CHAIRMAN dissented from this view.

The MANAGING DIRECTOR (Major Wood): Many of these people are dead.

Mr. W. GRIFFITH said that the previous shareholder had stated a most interesting point with respect to unpaid dividends. He feared that the item was owing in several cases to old age of the shareholders to whom the money belonged. He had had two or three instances where, in consequence of old age, people got out of business habits, and lived in straitened circumstances although they were possessed of riches. He had had to go to the Bank of England on one or two occasions on this account. He might also state that they would in time probably find the Chancellor of the Exchequer come upon them for these unclaimed dividends—property which the Company had a perfect right to appropriate if no claim was made for it. He had in the case of one or two companies proposed the insertion of a clause in the Articles of Association to the effect that after the lapse of a long period of time, the unclaimed dividends should belong to the Company. Of course, the Company would never think of retaining them when anyone rightfully appeared to claim them, but if no one claimed them the Company would have the benefit of them instead of the Crown. He considered this was a legal point worth consideration, and it was perfectly possible to carry out his suggestion by a small alteration in the Articles of Association. He thought they were indebted to the Chairman for the calm and statesmanlike way in which he had presented to the meeting the condition of their affairs at the present moment. They were an ordinary trading Company, but at this particular moment they were entering into the paths of statesmanship and politics, and it therefore required that their affairs should be under good guidance. He had been in hopes that before this time the Brazilian Government, which had raised expectations and hopes rather of a golden future for them, would have carried out their plans of politics and statesmanship, and have done what would have been not only a just thing towards the Company, but an advantageous thing towards the Brazilian public at large. However, they seemed to be dilatory, and the expected purchase of the Company's property had not yet taken place. On the other hand, they still remained an ordinary trading Company, and it was incumbent on them to be very careful how they carried on their ordinary business. The better their business and the more substantial the character of their concern, the more likely a foreign Government would be to acquire it. He afterwards referred to the balance sheet, and said that looking at the immense character of their undertaking and the fact that their reserve fund was under £30,000, they hardly possessed the sinews of war necessary to enable them to carry on a contest with others. They also owed £40,000 to other companies for messages. He found from their Articles of Association that it rested with the auditors to declare the amount of the net profit. He thought it would have been safer to have carried a much larger sum to the reserve fund, even though the dividend would in that case have been smaller. He alluded to the recent legal decision respecting the liability of auditors, and expressed a doubt whether a firm could be held liable, although an individual might be; and he proceeded to argue in favour of there being two auditors instead of one firm. He would propose at the next meeting that there should be two auditors instead of one.

A SHAREHOLDER: Whom would you suggest should be appointed?

Mr. GRIFFITH said he would be happy to act himself as the second auditor. He took a great interest in the Company, in which he had a large stake, and with which he had been connected for many years. He thought they would all agree with him that they were indebted to the Directors for having piloted them through somewhat dangerous and difficult waters.

Mr. FRY observed that the Western and Brazilian Company were the largest shareholders in the Platino Company, and he desired to ask how the sum of £1,200 Directors' fees would be dealt with.

The CHAIRMAN: I have no hesitation in saying that, having been so long without any fees at all, having given them up for the benefit of the shareholders until the amount paid to the former Directors was liquidated, I shall, as far as I am concerned, require my fees in the future. With respect to altering the Articles of Association in connection with the unclaimed dividends, the hon. and learned gentleman (Mr. Griffith) is quite right in what he says, but we did, I believe, make an effort to get in a clause which would enable us to take possession by effluxion of time of this unclaimed money. The Stock Exchange, however, would not pass it.

Digitized by Google

A SHAREHOLDER: They never will.

The CHAIRMAN: I suppose they never will. With respect to the reserve fund being only £30,000, it must be remembered that out of the reserves of the Company a second through line has been laid down all the way from Pernambuco to the Plate. There has been no addition whatever to the capital for that line, which has all been laid out of reserves; and therefore you have an enormous representation of earning plant for your capital. With regard to the creditors, in all these companies these things overlap. The hon. proprietor called attention to this £40,000 of debts. That is simply on message accounts, but had he looked on the other side, he would have seen £64,000 of bills receivable and not discounted, and some £19,000 odd of cash. You therefore see that the outcome of these figures, instead of being anything deplorable, is rather cheerful and encouraging, as it seems to me. We should have liked to carry more to reserve, but under the circumstances mentioned—the duplication of this cable and the payment of all these things out of revenue—we thought we were doing sufficient, and that the shareholders, who have allowed this policy to be carried out practically at their own expense, were entitled to some consideration. Therefore we made a little spring in the dividend, and as far as I am concerned I wish the improvement had been much greater. As regards our auditors, Messrs. Turquand, Youngs and Co. are a very first-class firm, and the whole subject of the auditors was very fully discussed at our last meeting. It was purely a shareholders' question, and it was felt by them—and decided by them entirely without us—that one auditor was sufficient, and, as far as my opinion is worth anything, I think they were right. If you have a first-class firm of accountants, what is the good of duplicating the work? We had that system before. With the firm of Messrs. Deloitte, Dever, Griffiths and Co., and the firm of Messrs. Turquand, Youngs and Co., it seemed a monstrous waste of time for both firms to go all through our figures one after another, just as if no one else had examined them. As a matter of fact, it was two audits instead of one. He then put the motion, and it was carried unanimously.

A vote of thanks to the Chairman and Directors brought the meeting to a close.

West India and Panama Telegraph Company (Limited).

The thirty-seventh ordinary general meeting of the members of this Company was held at Winchester House, Old Broad-street, London, on Wednesday, under the presidency of Mr. C. W. Earle.

The SECRETARY (Mr. R. T. Brown) read the notice calling the meeting, and the report of the Directors was taken as read.

The CHAIRMAN said: Gentlemen, you have do doubt observed in the report the recurrence of a clause which has become monotonous with us, announcing a decrease in the traffic receipts for the half-year in comparison with those of the corresponding period of the previous year. This is the fourth consecutive report in which we have had to announce such a reduction. During the whole of the half-year every station has been in communication, and the service has been carried on without complaint on the part of anyone. Then it may occur to you to ask, What is this reduction going to lead to, and to what is it attributable? A little time ago I saw the report of a meeting of the Demerara Railway Company, at which the Chairman, a gentleman long connected with the West India trade, and well qualified to speak on the matter, attributed the decline of their traffics to the decline in the sugar trade; and, no doubt, the unfortunate position of the West Indies in the low price of sugar that has ruled for a good many years past has very much prejudiced our traffics as well as those of other undertakings. But in seeking to be quite certain of what is the real cause of the depreciation, I have taken some trouble to look into the traffic accounts, which we divide in this Company into two classes. One we call the international traffic—that is, messages coming on to or going off our lines to other places beyond our system; and the other is called the intercolonial traffic, which is only the messages passing between the different colonies served by us. Well, I find that whereas in the year 1885—ten years ago—our intercolonial traffic amounted to £15,722 for the year, it only amounted during the year 1894 to £8,644, very nearly a reduction of 50 per cent. I may point out at the same time that the international traffic was only about 9 per cent. less in 1894 than it was in 1885. It is quite fair to presume that if our traffics were only affected by the general decline of commercial prosperity in the West Indies, it would have affected both classes of traffic equally; but from these comparisons we see that it is the intercolonial traffic that has been so very much depreciated; and I am informed that the reason of this falling off in our intercolonial traffic is the great increase in the number of "tramp steamers" which ply now to the West Indies. In former days a great part of our intercolonial traffic arose from the messages that passed for finding and chartering ships—agreeing as to freights, and so on. Now, no doubt, the merchant who has a cargo to send away waits for the arrival of what they call "the tramp,' which comes in and plies for freight very much as you see cabs crawling about the streets of London plying for fares. I have no doubt that has caused the great falling off in our intercolonial traffic. As I used the word "monotonous" with respect to the general tone of our report on the traffic, I may mention that a few weeks ago I received a letter from an honourable proprietor in our Company criticising these reports and my speeches in that respect, and saying that really a stereotyped edition might be published, and that with alterations of dates and figures it might be used every half-year; and he wanted to know what we were doing to remedy this state of affairs. Although the letter was rather cynically expressed, I thought it was a fair question to put, and also that the criticism was fair. I therefore invited this gentleman, with whom I had had no previous acquaintance, to meet me at the office to show him what we had done to try and improve our traffics. I explained to him that we had sought all round the shores of the Caribbean Sea for sources where we might obtain traffic to feed our system. We sent our general superintendent down to various places. He interviewed the merchants and consuls in several ports, but although those gentlemen were delighted with the idea of having a telegraph cable laid to their places of business, yet they were honest enough to say that they did not think we should get much traffic. We then asked whether the Government would give us a guarantee or a subsidy, and they replied that the Government would be delighted to grant us a subsidy, but that whether they would pay us was another matter. With the chilling prospects we had from these investigations we thought it was better to leave the matter alone, and the honourable member expressed himself satisfied that we had done what we could. We do not, of course, mention all these negotiations in our report—it is not our business to do so; but still, we are not letting things sleep for the want of inquiry or the want of energy in trying to push the business. With respect to the accounts, there is, as usual, very little to say. The charges are almost on the same scale and lines that they have been for years. In Abstract A it appears that we have spent £12. 9s. less than in the corresponding period of the previous year, and that in Abstract B we have spent £200. 7s. 3d. less; while in Abstract C—which refers to the repairs and renewals of cables—the sum expended was £2,524. 14s. less than in the corresponding period of last year. The whole boils down to a total of £18,000, the amount to the credit of the revenue account, against £16,109, and so far the result may be considered fairly satisfactory. I shall be very happy to answer any question that any member wishes to put to me. I must, however, before concluding, express our regret at the resignation of the Right Hon. G. W. Balfour, M.P., which he was obliged to tender owing to his having accepted the important office of Chief Secretary to the Lord Lieutenant of Ireland. It was a great advantage to us to have with us a man of his power and grasp, and of his great knowledge of the views of Parliament and of Governments. We do not propose to fill up this vacancy from economical motives. It may throw a little more work on the remaining Directors, who are now very few, but still we think that the fees had better be saved, considering our position. I have now to move—

"*That the Directors' report and accounts to June 30, 1895, submitted to this meeting, be and the same are hereby received and adopted, and that, as recommended by the Board, dividends of 6s. per share on the First Preference shares, 6s. per share on the Second Preference shares, and 1s. 3d. per share on the Ordinary shares (the last free of income tax) be and the same are hereby declared.*"

Mr. WILLIAM ANDREWS seconded the motion.

A SHAREHOLDER inquired when the dividend would be paid?

The SECRETARY replied that the warrants would be sent off that day, and the dividends be paid on the following day.

Mr. W. GRIFFITH said he was sure they all regretted the loss which the Company had sustained by Mr. Balfour's resignation. He was glad to find that the Board were economically inclined, and that they did not intend—he would not say to fill up the vacancy at present, but to take the fees which might have accrued from Mr. Balfour's retirement. There was one other point he desired to draw attention to. In these days, when the position of an auditor was somewhat equivocal, when he was considered an officer of a company, and liable to actions in Court, people were becoming somewhat suspicious. The very fact that the judges had declared that Mr. Theobald was liable had caused the public to think that all audits were not what they ought to be. In the case of their Company, the standing of the firm of auditors employed by them was so great that that suspicion could not for a moment be entertained. He had the pleasure of knowing Messrs. Deloitte, Dever, Griffiths and Co., who were gentlemen of the highest repute, but at the same time he thought that the public ought to be considered. If the public found that they were restricting the audit, that they were only having one auditor instead of two, as the Articles of Association permitted, the public might suspect what certainly was incorrect—that there was a desire on the part of their Company to conceal things; but nevertheless he thought they ought to consult public opinion as far as possible by having a shareholder as an auditor, as well as the eminent firm of accountants in question.

The CHAIRMAN: I must say, Mr. Griffith, that I cannot agree with you. I do not think it would be for the advantage of the Company to appoint a second auditor, or that it would have any influence on the public if we did. Nothing can exceed the confidence which is felt in the firm of Messrs. Deloitte, Dever, Griffiths and Co.

Mr. GRIFFITH: I said so.

The CHAIRMAN: I have had experience of another company of the same nature as this, in which duplicating the auditor—I think at your suggestion—caused a great deal of inconvenience, and that was repealed the other day, the company reverting to the system of having only one auditor. I do not think there would be any advantage in our appointing a second auditor, and we have to save every shilling we can. Your proposal, therefore, would not have my support.

Mr. GRIFFITH intimated that he would bring forward a motion on the subject at their meeting.

The CHAIRMAN then put the resolution, which was carried.

On the motion of Mr. GARROD, seconded by Mr. TERRY, a vote of thanks to the Chairman and Directors was passed.

The CHAIRMAN: I thank you for your kind vote. To receive the support of our shareholders is, I may say, one of the few satisfactions we have in administering this Company.

The proceedings then terminated.

Electro-Chemical Company (Limited).

The second ordinary general meeting of this Company was held at the Company's offices, St. Helens (Lancs.), on Tuesday, November 5th, Col. T. J. Holland, C.B., presiding. The following is abstracted from a report of the proceedings supplied by the Company.

Digitized by Google

The CHAIRMAN said: Since our statutory general meeting in London last year our registered office has been removed from London to the works at St. Helens, and therefore we hold this meeting at the works to enable shareholders to satisfy themselves as to the progress made in our manufacturing operations in the district in which our principal business will be transacted. We have been much occupied during the past year in making the necessary arrangements to enable us to commence manufacturing operations as soon as practicable, with a due regard to future commercial success, and have been very careful in selecting the best and most desirable site for our works, and very cautious in choosing and ordering the best and most reliable plant and machinery for our manufacturing purposes. If we had hurried matters, and, with the object of making an early start, had selected even the very best of the many sites first offered us for our works, or had hurriedly ordered in plant and machinery, without very careful thought and consideration, we certainly might have gained some credit for starting a few months earlier, but, on the other hand, we should not have been able to look forward with anything like the confidence we now do to the future success of our operations. When it is remembered that we shall require for our manufacturing operations some 1,600 million gallons of water annually, the selection of a site where a very large, continuous and inexhaustible supply of good and pure water, at a minimum cost, from more than one source, is obtainable, must be a matter of vital importance for such works as ours, and I feel sure that by far the best premises available have been selected here at St. Helens, and have, moreover, been obtained on most advantageous terms for this Company. Under all circumstances, therefore, I think even the most impatient of our shareholders must admit that we did well and acted wisely in waiting till we could secure such premises as these. Great care and forethought have also been given to the obtaining of the best and most efficient plant and machinery for our manufacturing purposes. We visited the works of several engineering and other firms, and having satisfied ourselves as to the best, the most efficient modern electrical engineering plant required for our purposes, careful specifications were prepared by our eminent consulting electrical engineer, Mr. James Swinburne, tenders were invited from some of the principal manufacturing engineers in the country; such tenders as Mr. Swinburne recommended were accepted, and contracts were made with the parties concerned; then buildings were adapted to suit the requirements of engines, dynamos, boilers, economisers, electrolytic tanks, and electrical generating plant generally; large water mains were laid for our condensing water to the St. Helens and Mersey Canal, and bleach chambers, caustic pots, furnaces, and other alkali appliances were all put in hand. An exceptionally severe winter prevented our progress quite as rapidly as we might have wished, and the unforeseen, the extraordinary, and the apparently unaccountable dilatoriness of the manufacturing engineers (whose weeks seem each to have numbered about 30 days) in delivering their engines and dynamos caused further delay, when all else was ready. However, all these delays now being over, we are happily at work at last, having made a good start on a good site with good plant, and I trust with good and efficient machinery, all of which I am sure you will be pleased to learn has been purchased, and erected at figures lower, instead of higher, as is usual in such cases, than the original estimates, and we have proved and are daily practically demonstrating to the sceptical chemical world, to the expectant electrical profession, that purer and better bleach and caustic soda can be made by our simple electrolytic process than by any of the older processes, and can moreover be so manufactured at something like 50 per cent. less cost. Now, gentlemen, I know I am addressing a body of shrewd, practical business men; one expects to meet such at a business meeting of this sort, especially in such a county as Lancashire. I am aware, too, that some of those present listening to me are interested in, and understand the details of, alkali manufacture by the older processes, and that others present also attending to my words are electricians, engineers and chemists, and are thoroughly conversant with matters connected with electrical engineering, chemistry, and electro-chemistry, and I know also that all present have to-day themselves personally carefully examined and critically inspected our premises here, their surroundings, their situation generally, their buildings, plant, and machinery; yet, notwithstanding all this information before me—and it is enough to make me very careful as to what I say—I have no hesitation in stating, even before such an audience, without fear of contradiction, for I know every practical man who understands the sort of work we have been engaged in, will agree with me that we, your Directors or Mr. Leith, your General Manager, could not, under all the circumstances, have pressed matters forward more rapidly than has been done, with a due regard to the future success of our operations, and I am confident, too, that all who have had any practical experience in starting large new manufacturing works will also agree with me when I say that, considering the size, the magnitude of these works, and the many most important details, some of them quite of a novel nature, requiring very careful consideration and attention, it is really a matter of sincere congratulation for us all that we have been able to start, and make such a good start too, as soon as has been done. In regard to the sale or working of our valuable foreign and colonial patents, we felt that until we could show our works in active operation in our own country, little or no advantage could be gained by pressing the sale or working of those patents in other countries. These patents have been kept up, and if the process continues to work as satisfactorily as it has begun to do here, and if it proves as profitable as we hope and believe it will do, we have applied for additional patents in India, Russia, Spain, Sweden, Norway, Denmark, Portugal, Turkey, Mexico, Argentina, Chili, Brazil, Uruguay, New South Wales, Queensland, South Australia, Western Australia, Victoria, New Zealand, Tasmania, the Cape of Good Hope, Natal, and the Transvaal. All these patents, together with the Foreign and Colonial patents originally acquired by this Company on its formation, we hope to dispose of in due course at very remunerative prices. Our Russian patent rights have already been sold subject to a short test of the working of the process here at St. Helens, which test will probably take place this month. As the demand for caustic soda and bleach in Russia is very small, we therefore thought it desirable to accept at once the best bona-fide offer from a solvent and reliable party, and have sold the Russian patents for £6,000. Our process has been at work for some time in a paper mill in France, where the plant and machinery for it were erected by our own men under the supervision of our General Manager; the working there has, I believe, given every satisfaction. The practical results of the working in France, like the practical results so far of the working here at St. Helens, have proved even better than those obtained during the two years the process was worked at Snodland, in the county of Kent prior to the formaton of this Company. Considerable interest has also been shown in our process and patents by papermakers and others in Austria-Hungary, Belgium, Spain, Mexico, Canada and Italy, with all of which countries we have lately been in negotiations for the sale of our patents. I hope our plant and machinery will shortly be erected in a paper mill in Italy. We have refrained from issuing licences to papermakers and others to work our process in their paper mills or factories in the United Kingdom until our own works were completed, and until we could clearly ascertain the best, the most economical and the most compact form in which the plant and machinery required should be constructed to fit into the limited space available in the works of alkali users.

I have been asked to say a few words on the Castner electrolytic process recently advertised. So far as I can see, that process does not affect or touch us in any way whatever. Their patents were taken out some two or three years after ours, and therefore they cannot take advantage of any part of our inventions. We use iron cathodes, which last a long time, and cost 1s. 8d. each, or about £1,000 for all our 800 large electrolytic tanks, capable of producing 20,000 to 30,000 tons of 70 per cent. caustic soda and bleach annually. They use mercury cathodes, which will cost them, at a very low calculation, £7 each, and this for a plant with the same number of cathodes as we shall have, and the same sized plant as ours, means over £80,000 for mercury alone. Mercury is a liquid metal readily volatilised, and, as we know from our barometers and thermometers, is highly sensitive to atmospheric, climatic, and thermotic influences, and its evaporation is very dangerous to human, animal and vegetable life. They use heavy oscillating electrolytic tanks, far more costly and less durable than our fixed stationary tanks, and requiring machinery, belting, and power to drive, none of which are needed by our process; and their spindles oscillating machinery, and bearings are liable to get corroded and eaten away as soon as an escape of chlorine gas touches them, and they are surrounded on all sides by chlorine gas, day and night. In fact, theirs is a complicated, elaborate, costly system, working in the midst of the deadly volatilising fumes of mercury, which costs them at least 2s. a pound to produce caustic soda and bleach, the top sale price of which is ¾d. a pound! We use no re-agent or oscillating machinery, no belting, driving gear, or bearings whatever, and our process is as simple as A B C, and works in a perfectly pure and healthy atmosphere. The success of our process has been thoroughly established by practical working on a large commercial scale; theirs is hardly yet out of the laboratory or experimental stage. They may make caustic soda and bleach cheaper than is done by the old Le Blanc process—I daresay they will—but they cannot come near us by at least some £20,000 a year spent on mercury and extra machinery. How, then, can the Castner process affect us in any way?

Mr. R. TAYLOR hoped that future general meetings might be held in London. He considered that Japan was a country in which the Company ought to have a patent. If more shares were issued he hoped the shareholders would be allowed to take them up themselves, as no doubt they would be very pleased to do.

The CHAIRMAN said that he personally also hoped future meetings would be held in London. In regard to Japan, the Japanese patent law was rather peculiar, as none but the Japanese themselves were allowed to take out patents, and all foreigners are absolutely shut out from taking such patents. At the same time he might state that a Japanese papermaker, in a good position in his own country, had already been over to England about the electro-chemical process, and wished to take a patent out in Japan for it; and they were now in negotiation with him. The Directors hoped to avoid the issue of more shares, at any rate for the present.

Mr. C. TYLDEN WRIGHT said that the site selected, the buildings, plant and machinery appeared all that could be desired for large chemical works. He considered that the manufacturing engineers had caused the Company a very serious loss by their dilatoriness.

A SHAREHOLDER asked if the General Manager was able to realise as high prices for their caustic soda and bleach as the United Alkali Company obtained.

The CHAIRMAN replied that they had never sold anything yet under the top prices fixed by the United Alkali Company; they found no difficulty in realising these prices, or in selling their products, on account of the purity of their bleach and caustic soda, which evidently, by the repeated orders they received, met with the approval of consumers; they had already sold about all they could make in 1896 unless the plant were enlarged.

After the Directors' report and accounts had been adopted, and the retiring Directors and auditors re-elected,

The CHAIRMAN proposed that a cordial and hearty vote of thanks be given to Mr. Leith, their General Manager, and to those who had worked under him so ably and well during the past year. Mr. Leith was a very able, experienced, and efficient chemist, electrician, engineer, and alkali manufacturer. The successful position they were in that day was to a very great extent due to Mr. Leith's ability, energy, and hard work, and to those who had worked under him so well.

The resolution was carried unanimously, and a vote of thanks to the Chairman and Directors brought the proceedings to a close.

Aluminium Company (Limited).

The eighth ordinary general meeting of this Company was held on Monday at the Cannon-street Hotel, E.C., under the presidency of the Right Hon. Gerald William Balfour, M.P.

The CHAIRMAN said: As regards the ordinary business of the Company, the gross profits this year amount to £17,000, against about £19,500 for last year. The difference is owing to the stagnation in the sodium trade, due to a very special cause, which is not likely to recur. The trade revived in the spring, and since then we have been, and still are, full of orders. The chief interest in the Company's affairs, however, centres in the developed value of the Company's patent. At our last annual meeting I alluded to the important question of the depreciation of our patents, and I then said that the Directors felt fully justified in stating that "the figures given in the balance sheet represent their actual value. What we have done is to write off an adequate amount for depreciation from the old patents, and to set down the patents connected with the new caustic process at a figure very considerably below what I believe to be their real value. That, of course, is right, because that value has not been realised. When it is realised I believe the balance sheet of the Company will show very much more favourably than it does now." You will no doubt agree with me that this year's report shows that the anticipations which the Board then formed are being verified. We have during the past year disposed of the Castner patents for the manufacture of soda by electrolysis. We have disposed of those patents all over the world, and the Company stands to receive in respect of them a sum amounting in cash and shares to between £150,000 and £200,000. Of this sum we stand to receive from the Mathieson Alkali Company in America £65,000, and, as the shareholders are aware, a company has been formed within the last few weeks, and we receive from that company in respect of those patents £100,000 in shares and £25,000 in cash. In addition to this, the Company owns another important chemical invention made by Mr. Castner, the exact nature of which I do not think at the present moment it would be advisable to disclose. We have sold the patents for that invention in the United States of America alone for a sum of £10,000 and a third of the capital of the Company which is to be formed there. We have yet to dispose of these patents in England and on the Continent of Europe. I therefore think we are justified, and more than justified, in making the statement as to the value of the patents which we made last year. On the general question of the value of these patents, and the value, therefore, of the shares which we hold in the Castner-Kellner Alkali Company, I would simply content myself by reminding the shareholders of the following facts. In the first place, Messrs. Solvay and Co., who are the greatest manufacturers of alkali on the Continent of Europe, have secured these patents, and are now erecting plant on a large scale to work them, while they have themselves invested in the English Company, after sending their expert over to Oldbury, who remained there watching the process for upwards of a week, night and day. I would remind you, further, that the process has been purchased by the Mathieson Alkali Company in America, with the advice of the greatest expert in chemistry in America, Dr. C. F. Chandler; and as it has been thrown in our teeth that this process has not been bought either by Messrs. Brunner, Mond and Co. or by the United Alkali Company, I will say this: I, myself, would welcome expressions of opinion either from Mr. Ludwig Mond, who first recommended this process to Messrs. Solvay and Co., or Dr. Hurter, who is the chemical adviser of the United States Alkali Company, both of whom had an opportunity of inspecting the process, and, as I have reason to know, formed a most favourable opinion of it. We have not studied this question for three years for nothing. We know the value of what we have sold, and I do not believe we have sold it for a penny more than it is worth. Last year I referred to the arrangement we had made with Mr. Castner, that he should receive 10 per cent. of the profits on anything derived from his patents, and in return give us the benefit of his inventions while he was connected with the Company, and that I regarded this as one of the most valuable assets the Company possessed. I think to-day you will all agree with me in that opinion. We, as a Company, owe a debt of gratitude to Mr. Castner for all that his inventive genius has done for us, but no less a debt of gratitude for the great business capacity which he has displayed. The Chairman then referred to his retirement from the directorship of the Company owing to his appointment in the Government, and expressed the pleasure he felt in having been successful in steering the Company through the most troubled waters which a public company had ever encountered without foundering, and in seeing the vessel brought safely into port.

Sir HENRY E. ROSCOE, F.R.S., seconded the adoption of the report, and announced that a satisfactory site for the Castner-Kellner Alkali Works had been acquired.

A dividend of 5 per cent. for the year ended June 30th last on the "A" shares was declared, and the retiring Directors (Gen. Sir Andrew Clarke and Mr. Castner) were unanimously re-elected, as were also the auditors (Messrs. Broads, Paterson and Co.).

A cordial vote of thanks to the Directors terminated the proceedings.

ST. JAMES'S AND PALL MALL ELECTRIC LIGHT COMPANY (LIMITED). The Directors of this Company recently issued a prospectus to their shareholders inviting subscriptions for £20,000 Four per Cent. Debenture Stock at a premium of 2½ per cent. The stock is redeemable at par on January 1, 1914, or previously on six months' notice, at a premium of 5 per cent. In February, 1894, the Directors created £100,000 Four per Cent. Debenture Stock, of which £30,000 was subscribed for, and it has now been decided to issue a further £20,000.

NEW COMPANIES, STATUTORY RETURNS, &c.

In addition to the information given under this heading, detailed particulars of many of the Companies whose returns appear below will be found in "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1895, pages *304-332, &c., &c.*

BRITISH ELECTRIC TRACTION (PIONEER) COMPANY (LIMITED).—This Company was registered on November 7th with a nominal capital of £100,000, in £10 shares, to acquire the rights comprised in (and for that purpose to enter into and carry into effect) an agreement expressed to be made between the Electric and General Investment Company (Limited) and this Company to acquire, construct, equip, maintain, repair and work any railway or tramway carriages, vans, cars, trucks, boats, or other vehicles and craft appropriate for the carriage of passengers or goods, to obtain any necessary licences for working the same by electricity or other motive power under the Hackney Carriage Acts, or otherwise, and to carry on in the United Kingdom and elsewhere the business of carriers of passengers and goods, electricians, engineers, contractors, manufacturers of and dealers in railway, tramway, electric, magnetic, galvanic or other apparatus, and mechanical and chemical engineers. The subscribers, with one share each, are:—C. Rivers Wilson, G.C.M.G., C.B.; Emile Garcke, electrical contractor; John S. Raworth, civil engineer; Robert Doyle, George Herring, J. Cecil Bull, and J. B. Braithwaite, jun. The first Directors are: Sir C. Rivers Wilson, G.C.M.G., C.B., the Right Hon. the Earl of Suffolk and Berkshire, Emile Garcke and John S. Raworth.

ROGER DAWSON (LIMITED).—The annual return to October 21st has been filed. The whole capital of £15,000, in £1 shares, has been taken up, and 14,993 have been issued as fully paid. The full amount has been called on the remaining seven shares.

CITY NOTES.

MEMORANDA.—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver, 30 1/16d. per oz. (Nov. 14th). Consols (2¾ per cent.) 106 1/16—106½ for money, 106 3/16—106½ for account; 2½ per cent. 104—104½ (Nov. 14th). Stock Exchange Settling Days: Consols, Dec. 2nd; Stocks and Shares Continuation Day, Nov. 26th; Ticket Day, Nov. 27th; Pay Day, Nov. 28th.

BRITISH ELECTRIC TRACTION (PIONEER) COMPANY (LIMITED).—Subscriptions are invited by the Electric and General Investment Company (Limited) for an issue of 5,000 shares of £10 each in the British Electric Traction (Pioneer) Company (Limited), which is, the prospectus states, formed "to take steps for the development of electric traction in the United Kingdom and elsewhere on systems which have already proved successful in the United States and on the Continent of Europe." The share capital of the Company is £100,000, in £10 shares, of which the present issue forms one half. £1 per share is payable on application, £1 on allotment and calls not exceeding £2 per share will be made as necessary at intervals of not less than one month. The prospectus will be found fully set out in our advertisement columns. A strong Board of Directors includes Sir Charles Rivers Wilson, G.C.M.G., C.B., and Mr. Emile Garcke is Managing Director. It will be seen that the Company is not committed to the use of any particular system, and that already some important inventions and proposals relating to electric traction have been submitted to the Directors. The only contract entered into by the Company is fully referred to in the prospectus, which contains no objectionable waiver clause. The list opens and closes this day (Friday) for both town and country.

CALL DUE.—To-day (Friday), Amazon Telegraph Company £10 shares—£2. 10s. per share.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended November 10th were £1,009, against £969 in the corresponding week of 1894, an increase of £40. The total receipts for the half-year amount to £16,658, against £16,719 for the corresponding period of 1894, a decrease of £61.

GENERAL ELECTRIC COMPANY OF AMERICA.—It is estimated that the profits on the year's working of this Company will suffice to pay a dividend of 3 per cent.

LIVERPOOL OVERHEAD RAILWAY COMPANY (LIMITED).—The traffic receipts of this railway for the week ended 10th inst. amounted to £1,063. The amount for the corresponding week last year was £892; increase, £171.

VICTORIA ELECTRIC RAILWAY AND LIGHTING COMPANY (LIMITED). The numbers are published of 25 Five per Cent. First Mortgage Debenture Bonds of this Company, amounting to £1,000, which have been drawn for repayment on and after January 2nd next, at the rate of 105 per cent. The bonds will be repaid at the office of Messrs. Sperling and Co., 8, Austinfriars, E.C.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended November 8th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,993.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861—1878.

No. 914. [Vol. XXXVI. No. 4.] FRIDAY, NOVEMBER 22, 1895. PRICE SIXPENCE.

NOTES.

FROM the report of the proceedings at the reception of the deputation of representatives of the Colonies by Mr. CHAMBERLAIN on Tuesday, it will be seen that the Minister for the Colonies is favourable to the appointment of a Joint Commission to consider and report upon the question of a Pacific cable. Owing to the extreme depth of water in places, the great length to which some of the sections must extend, the various possible routes, the probability of the maintenance being exceedingly costly, and the necessity for large subsidies from the Imperial Government and the Colonies interested, it is desirable that the whole matter should be carefully and judicially considered, and the opinions of authorities on cable matters heard. It is satisfactory, therefore, to find that there is prospect that the Government will decide to take action in the direction indicated. Mr. CHAMBERLAIN is reported to have said that there was evidence that the amount of traffic over such a line would be satisfactory, but no one believes that this enterprise, unless subsidised, could be carried on without large deficits, and the laying of the line is entirely dependent upon the amount of Government aid forthcoming. With direct steamship and cable connection doubtless a considerable trade will spring up between Canada and Australasia, but obviously it will take years to grow. So far as this country is concerned—apart from its colonies—the principal argument for the line in question is the strategic one; as the average time occupied by messages between London and Sydney is only two hours, and the rate of 4s. 11d. per word is a moderate one for the distance (16,000 miles). However, Canada and the Australasian colonies—and especially the former—will not rest satisfied until they get a direct cable. Whether the connection will effect all they seem to expect from it is, to say the least, doubtful.

AT a special meeting of the Brighton Town Council on Saturday last the Brighton and Rottingdean Seashore Electric Tramroad Company confessed to having made fundamental alterations in its original plans, and withdrew all imputations of obstruction on the part of the Corporation. Having thus purged itself, the Company was graciously permitted to erect "13 tubular poles 80 yards apart" along the Brighton foreshore on agreeing to enter into a bond for £1,000 to remove the rails, &c., if the working of the line is at any time abandoned.

THIS desirable consummation was not, of course, reached without a lengthy debate, the only item of interest being the figures given by the Company's engineer, Mr. ST. GEORGE MOORE, with regard to the estimated horse-power required to propel the 60-ton perambulatory pier. "At low tide, with an incline of 1 in 300 on a 40-chain curve against a 14-mile wind, 24 H.P. would," he said, "be necessary for a speed of six miles an hour; running with bogies in the water, 40 H.P. would be needed under similar conditions, and with the car submerged, 63 H.P." Well, we hope it will be so, and trust that this little line may prove as commercially successful as it is electrically and mechanically interesting.

THE Paper by Dr. ROESSLER, the first portion of which will be found in another column, should be of interest to those concerned, either practically or theoretically, with transformer working. The statement that the magnetising current of a transformer can be reduced 30 per cent. by the adoption of a peaked E.M.F. curve will be welcomed by alternate-current central station engineers blessed (?) with a too-pointed load-diagram. It is unfortunate that the condition for highest transformer efficiency should be the direct opposite of that for the best illuminating power of alternating arcs. Up to the present, however, arc lamps are in this country chiefly used for street lighting, and alternate-current arcs are for this purpose the exception, and not the rule. The question of insulation is of greater importance as an objection to the pointed E.M.F. wave, but so long as actual disruptive discharge is prevented the virtual leakage current would be the same for all curves having the same virtual potential difference. It is very probable, also, that there would be no need to increase the insulation to prevent disruption, for, as has been shown, transformers under ordinary conditions of working are subjected to potentials of many times their usual value when the primary circuit is made or broken. It is these abnormal potentials which determine the degree of insulation required for a transformer, and as they would not be increased, but somewhat diminished, with the pointed curve (since Dr. ROESSLER shows that the maximum magnetic induction is less for pointed curves), there would be no need of higher insulation. In these circumstances there seems no reason why we should not take full advantage of the beneficent properties of the peaked E.M.F. wave.

WE have always considered that there existed an element of scarcely justifiable empiricism in the commonly-used formula

Digitized by Google

for the hysteresis loss in iron which makes the loss an exponential function of the magnetic induction. It was difficult to believe that any such connection between the two things really existed; and it was simply impossible to rationalise the formula on the basis of any modern theory of the magnetisation of iron. In a Paper which he read before the British Association at Ipswich, and which we reprint this week, Mr. F. G. Baily has given the results of, and drawn a definite conclusion from, a number of experiments which he has made on the relation between hysteresis and magnetisation in iron. Briefly stated, these experiments seem to show that energy is wasted by hysteresis during only that portion of the change in the magnetic induction which is accompanied, so to say, by molecular grinding. When the induction changes in a region beyond the limit of saturation, the absence of any molecular movement during the change accounts for an absence of hysteresis; and when the induction is carried between widely-separated positive and negative limits, it is only the induction between positive and negative saturations which involves hysteresis. It would seem, then, that inasmuch as hysteresis is a function of the magnetisation and not necessarily of the induction, we should, as Mr. Baily points out, express the hysteresis in terms of "the intensity of magnetisation, with at most a small correction in terms of the latter quantity (the magnetic induction)," and not directly in terms of the magnetic induction itself.

The services rendered by the gas engine to electric lighting have been extensive and manifold. This engine has not only been used alone, both in public and private plants, but a useful field has been found for it as an adjunct to steam stations. Usually the supplementary gas-engine plant is to be found along with the steam engines in the same station; but at Brussels this practice has been modified in an interesting manner, by putting the auxiliary gas plant in a separate sub-station situated at some distance from the main station. The site chosen is a large vault beneath the Belgian State Railway Offices; and here the India Rubber and Telegraph Works Company, of Silvertown, have recently installed two out of a total of five generating sets, which it is intended ultimately to provide. Each set comprises a 120 H.P. twin cylinder gas engine, working on the "Otto" cycle, direct-coupled through Raffard clutches to two dynamos, one at each end of the crank shaft. The set runs at 150 revolutions per minute, and at this speed the dynamo gives a normal output of 320 amperes at 125 volts. The sub-station is provided with a storage battery of Julien cells, having a normal capacity of 250 amperes at 250 volts for eight hours' discharge. One of the features of special interest in this sub-station is the direct-coupling of the gas engines. Such engines have long been adopted in various stations on the Continent; but until recently they had not made their appearance in this country. Indeed, we have heard it stated more than once that the flexible belt between a gas engine and a dynamo is necessary to steady running of the latter. No such necessity appears to have been recognised in the successful stations of the Continental Gas Association, nor at Brussels; and we were glad to hear, the other day, that the additional plant for the Belfast gas-power electric supply station is to consist of direct-coupled engines and dynamos.

When drawing up rules or giving advice in regard to electric lighting, an insurance company is not likely to err on the side of laxity; but it would seem that its officers may be unnecessarily over-cautious. In an article contributed to the *Paper Makers' Circular*, Mr. L. M. Mann, of the North British and Mercantile Insurance Company, discusses the use of various artificial sources of light in paper mills, and the fire risks attendant thereon. After recounting the obvious and numerous precautions which are necessary with gas jets, he says:—

"With regard, now, to the lighting by electricity, there are dangers in connection with the lamps which call for safeguards not less evident than those just mentioned. For example, the surface round the top of the bulb of an incandescent electric lamp in the dry department is apt to become thickly coated with fluff and dust. Such a deposit upon the heated surface of the glass is dangerous, and should be prevented from forming by placing the lamp in an outer glass globe arranged to exclude dust."

Mr. Mann does not tell us in what way such a deposit of dust might be dangerous, but as the article is on fire risks we suppose it is a danger from fire that is apprehended. We should be surprised to hear that even an incipient fire had really ever originated from such a cause. At the same time the use of an outer globe is not altogether inadvisable where the atmosphere is so laden with dust that an explosion might result, from the fracture of a lamp bulb bringing a portion of the still glowing filament into contact with the explosive mixture of dust and air.

A few weeks ago we had occasion to express our well-grounded doubt in regard to the alleged high speeds attained by electric trains on the Nantasket Beach railway, in the United States. The claims for speeds rising to 80 miles an hour advanced by the parties interested in that railway, were, in our opinion, and taking into account the local circumstances, utterly unjustifiable. We are led to revert to this matter because of similar claims which have recently been advanced in favour of a train running on the Lake Shore and Michigan Southern Railway. It has been stated that a steam locomotive, with six-coupled driver wheels, drew a train weighing 136 tons a distance of 510 miles at an average speed of 64 miles per hour, including all stops, many miles being covered at a speed exceeding 72 miles per hour, and a maximum exceeding 90 miles an hour occurring over one mile of the run. It is time that these startling claims, of which the two already mentioned are by no means the only instances, should be disproved or else should be based upon better evidence than is at present forthcoming; and we are gratified to see that our contemporary the *Engineer* has investigated the matter very thoroughly, and has upset the claims, in the case of the Lake Shore Railway, by a complete *reductio ad absurdum*.

Coventry.—The municipal electric lighting station of this town was opened on Saturday last, November 16th.

Cable Interruptions:—	Date of Interruption.
Cadiz-Teneriffe	Sept. 25, 1895.
Perim-Assab	Nov. 19, 1895.

Sydney University Engineering School.—A Sydney engineer, named Mr. P. N. Russell, has given £50,000 for the endowment of an engineering school in the Sydney University.

The Frédureau Diffusing Globe.—The light-diffusing globes invented by M. Frédureau, to which frequent reference has been made in our columns, is now being introduced commercially into this country.

Royal Society.—Among the Papers down for reading yesterday at the Royal Society was one by Mr. G. J. Burch "On the Calibration of the Capillary Electrometer." An extra meeting for the reading of Papers will be held on November 28th.—— The anniversary meeting will be held on Saturday, November 30th, at 4 p.m.

Birmingham Municipal Technical School.—We have received a programme of the classes in theoretical and applied science for the ensuing session at the Birmingham Municipal Technical School. The classes in electrical engineering and physics are under the direct tuition of the principal, Dr. W. E. Sumpner, assisted by Mr. Coultas.

Obituary.—The death occurred, at his home, 337, West 22nd-street, New York, on October 25th last, of Mr. Holbrook Cushman, at the early age of 38 years. Mr. Cushman was well known amongst electricians in this country about 10 years ago, at which time he was head of the electrical department at Messrs. Mather and Platt, after which he returned to America and became an instructor in the physical department and head of the laboratory at Columbia College, New York. The cause of death was heart disease. Amongst other institutions, Mr. Cushman was a member of the American Institute of Electrical Engineers.

The Central London Railway.—The experimental boring beside the Bank of England, which was instituted in connection with the proposed central junction station for the electric railway, to ascertain the character of the sub-soil, has now been completed. Made earth was found down to a depth of something over 13ft. then came a layer of gravel, then one of clay, then ballast, and, at a depth of about 30ft. that good foundation and excellent material for working through, the London blue clay. Nothing of antiquarian interest was discovered in boring.

Electric Lighting in Germany.—At the first autumn meeting of the Berlin Elektrotechnischer Verein Herr von Stephan, in his Presidential address, gave some interesting figures as to the present state of electrical enterprise in Germany. There were in actual working on October 1st in the German Empire, with the exception of Bavaria and Wurtemberg, 7,419 installations. Of this number 7,108 served mainly for lighting purposes, with a total number of 1,380,000 glow lamps and 61,000 arc lamps. Further 90 installations were mainly used for electrolytic purposes and 453 for transmission of power. These figures, the President said, were not quite correct, as information in some instances was difficult to obtain, but, in his estimation, they were rather below than above the actual figures.

Royal Society Medals.—The Royal Society's medals have this year been adjudicated by the President and Council as follows:—The Copley Medal to Prof. Karl Weierstrass, For.Mem.R.S., for his investigations in pure mathematics; a Royal Medal to Prof. James Alfred Ewing, F.R.S., for his investigations on magnetic induction in iron and other metals; a Royal Medal to Dr. John Murray, for his services to biological science and oceanography in connection with the "Challenger" reports, and for his original contributions to the same; and the Davy Medal to Prof. William Ramsay, F.R.S., for his share in the discovery of argon, and for his discoveries regarding gaseous constituents of terrestrial minerals. The medals will, as usual, be presented at the anniversary meeting on St. Andrew's day (November 30th). The Society will dine together at the Whitehall Rooms on the evening of the same day.

Electric Car Accident.—A terrible accident occurred at Cleveland, Ohio, on November 17th, at eight o'clock in the evening. An electric car, conveying between 20 and 30 persons, plunged over a drawbridge in the central part of a viaduct and fell into the Cuyahoga river 100ft. below. The viaduct is 3,000ft. long, and when the car was approaching the middle, where the drawbridge is situated, the conductor went forward. Although the gates across the road were closed, he signalled the way clear. The motorman accordingly turned on the current, and the car dashed through the gates and fell into the water. Several persons, including the motorman, jumped off, but all those remaining in the car were drowned. Thirteen bodies have already been recovered. The motorman, Rogers, has been arrested. He stated that the conductor, who was drowned, gave the proper signal for the car to proceed.

Electrical Manufacturing Activity in Germany.—The report of the Allgemeine Elektricitäts-Gesellshaft of Berlin for 1894-95, just issued, contains some interesting figures as to the continued growth of this large concern. The number of employees has increased from 3,385 to 5,121, and consequently the output of the different departments has been considerably greater than in the preceding year. No less than 2,049 dynamos and electric motors were manufactured of a total capacity of 22,800 kilowatts, or about 30,000 H.P. At present the Company has in hand orders for 2,000 dynamos for a total capacity of 58,500 kilowatts, or nearly 80,000 H.P.; 26 of these machines are to be over 1,000 H.P. each. In the traction department the number of tramways on the "A.E.G." system, either in working or in the course of erection, has increased from 19 to 29, the total length of line from 120 to 237 miles, and motor cars from 350 to 680. The generating stations of these lines represent a total capacity of 11,230 H.P., as against 5,950 H.P. in the preceding year.

Finsbury Technical College.—From the recently-issued report we learn that the Finsbury Technical College is making good progress. Referring to the work done in the mechanical and electrical engineering departments, Dr. Silvanus Thompson, the principal, writes in his report:—

"The past students of the two engineering departments can also show a good record of subsequent successes. All over the country Finsbury students are to be found, as engineers or assistant engineers, in the electric lighting stations. At Oldham, Taunton, Tunbridge Wells, Belfast, &c., and at various stations in London, including the City and South London Electric Railway, they may be found occupying posts of responsibility. . . A scrutiny of the present occupations of the certificated students in the list appended to this report will show how large a proportion are pursuing careers of which their college course was designed to prepare. . . . Of the uncertificated past day students, and of the past students of the evening classes, no similar register exists; but as the vast proportion of evening students are already employed in the cognate industries at the time when they enter the classes, it is probable that a still larger proportion remain in the industries which the college classes are designed to aid. It cannot be expected, now that the electric lighting industries are so overstocked with young men, that during the next ten years there will be the same pressure toward classes for electric lighting as has existed during the past ten. But other fields are opening in the extended use of electric motive power, and in the applications of electricity to metallurgy and to manufacturing chemistry."

The Telephone in Yorkshire.—On Wednesday, at the General Post Office, a deputation from the West Riding of Yorkshire waited on the Postmaster-General to urge upon him the necessity for increased facilities in telephonic communication in Yorkshire. Mr. Arnold, M.P., said he wished to emphasise the fact that in the part of Yorkshire which they represented there was a very large manufacture of soft goods carried on. The material, in the process of its manufacture, had to go to different towns in the West Riding, so that between these different towns there ought to be absolute freedom of communication as an essential thing. To secure this end he would advocate an increase in the number of trunk wires and the uniting of the various towns which they represented in one telephonic area. The Postmaster-General, in his reply, said that he should only be misleading them if he held out hope of only being able to accede to the first request. The areas had all been specified and drawn up carefully, while the deputation asked that they should all be thrown into one. The authorities were anxious to do all they could in the direction of increasing the number of trunk wires, but even if everything was granted that was asked for, there were limits to the perfection that was attainable.

Proposed Amendment to the Electric Lighting Acts.—The Directors of the City of London Electric Lighting Company

Digitized by Google

invited the delegates to the Board of Trade Conference to a meeting at Winchester House on Monday last, with the object of an interchange of views on a proposal to appoint a deputation to wait upon the Board of Trade to suggest certain amendments to the Electric Lighting Acts. The Local Authorities represented at the meeting included the Corporations of Worcester, Burnley, Glasgow, Coventry, Tunbridge Wells, Newport and Eccles, and the Vestries of Hammersmith, Hampstead and Acton. The companies representatives present, in addition to the City of London Company, were the Westminster, Metropolitan, Charing Cross and Strand, Chelsea, Bournemouth, Oxford, Eastbourne, Hove, Sheffield and Altrincham. The chief subject discussed was the clause in the Acts which enables an individual with only a small property rights in the neighbourhood of an electric supply station to obtain an injunction, resulting in the stoppage of the electric lighting works, to the great inconvenience of the public and the serious pecuniary loss of the supply company or local authority. Several speakers commented upon the unworkability and injustice of the clauses as they stand, and the suggestion that a deputation should wait upon the Board of Trade to place the views of the meeting on this and other subjects was approved.

The Proposed Pacific Cable.—Mr. Chamberlain received, on Tuesday, at the Colonial Office, a private deputation of Colonial representatives for the purpose of discussing the project of a Pacific cable. The deputation consisted of Sir Charles Tupper (Canada), Sir Saul Samuel (New South Wales), Mr. Duncan Gillies (Victoria), Mr. Thomas Playford (South Australia), Sir Robert G. W. Herbert (Tasmania), Mr. Walter Pease (Natal), Mr. C. S. Dicken (Queensland), Sir Westby Brook Perceval (New Zealand), and Mr. Spencer Brydges-Todd (Cape Colony). Mr. Chamberlain observed that such a meeting of the Council of the Empire, brought together for the purposes of common interest, and attended by representatives of the Cape and Natal, which were not concerned with the project in its present form, was an evidence of solidarity and sympathy. He expressed his opinion that the project showed a very fair prospect of remunerative return on the capital required, and his willingness to join in the formation of a joint Commission, which should report upon the subject. He suggested that a Commission should be formed, consisting of two representatives of Great Britain, two of Australasia, and two of Canada. After some discussion it was arranged that the Colonial representatives should be named by the Colonial Governments and appointed by the Imperial Government, and that the Commission should consider and report upon the subject in all its aspects. It was also arranged that the Agents-General and the High Commissioner of Canada would move their Governments to appoint representatives on this understanding.

Magnetic Charts.—At a recent meeting of the Académie des Sciences, M. de Bernardières, of the Bureau des Longitudes, made a communication on the subject of the new magnetic charts of the globe undertaken under the direction of the Bureau des Longitudes. M. de Bernardières remarked that the magnetic charts published at the present day by the English Admiralty and other authorities, rested mainly on observations taken by navigators, the scientific value of these observations being very different in different cases. With a view of affording a better basis for a magnetic chart of the globe, the Bureau des Longitudes recently decided to train a certain number of naval officers and travellers at the Mont Souris Observatory in the art of taking magnetic observations with the latest approved appliances. In this task the Bureau received warm support from the French Admiralty and Colonial Office. The result has been that seven expeditions, each consisting of a naval officer and an assistant, have been sent out with a view of taking simultaneous magnetic observations in different parts of the world. These expeditions have been distributed as follows: On the Atlantic Ocean observations will be taken on the west coast of Africa and the east coast of America; on the Pacific Ocean observations will be taken on the west coast of America and in Oceania; on the Indian Ocean observations will be taken on the Red Sea littoral and on south coast of Asia and in Madagascar; in the China Sea observations will be taken on the Chinese, Japanese and Indo-Chinese coasts; in the north observations will be taken in the North Sea and on the coast of Scandinavia, Denmark, Scotland and Iceland; in mid-Atlantic observations will be taken at Madeira, the Canary Islands, the Azores, Cape Verd and Senegambia. As soon as the Bureau des Longitudes possesses the necessary instruments, the eighth expedition will be sent to Newfoundland, and will afterwards take observations in the Mediterranean. In addition to these special expeditions the Department of Marine has arranged to instal special apparatus on ships circumnavigating the world, and have arranged for observations to be taken as accurately and as frequently as possible on ships only possessing ordinary navigating appliances. These expeditions are at work, and have already communicated preliminary results; their observations are to extend over a period of about two years. The expedition to Iceland, which left France at the beginning of last spring on the "Manche," has returned and brought back a rich harvest of measurements taken at Cherbourg, in Scotland, the Shetland Isles, Iceland, Norway (where they went up as far as Bossekop and Hammerfest), in Denmark, and in the course of crossing the North Sea. Two complete series of observations, each lasting a week, were carried out in a temporary observatory constructed at Rejkiawik. The comparison of these results, obtained with considerable accuracy, with the results obtained 60 years ago by the observers on the "Recherche," and since then by different magnetic expeditions in these regions, should prove of considerable interest.

Contemporary Electrical Science.—P. Lenard's further Paper on CATHODE RAYS in *Wiedemann's Annalen* formulates a new general property of matter in the thesis that, whatever the nature and state of aggregation of the absorbing material, the absorption is proportional to the mass; in other words, that the absorption of cathode rays by a definite thickness of material increases with its density. Hydrogen deviates most from this rule, in the proportion of about 5 : 3. Glass, silver, collodion, and sulphurous acid are also rather highly absorptive in proportion to their density, but paper, mica, and aluminium are less absorptive. "Lenard's law" is now in the same state as was Boyle's law of yore, and requires another Andrews or Van der Waal to put it right.——Messrs. Paalzow and Neesen deal with the PASSAGE OF ELECTRICITY THROUGH GAS, and attempt to measure the temperature of the discharge by means of the evaporation calorimeter. "Supposing all the particles to take equal parts in the discharge," the temperature obtained is 649,000°C.! This astonishing result is, however, only a secondary matter in an otherwise valuable Paper.——O. Lehmann's Paper on CONTINUOUS DISCHARGES IN GASES will be noticed more fully elsewhere. As for such discharges, there are none.——H. Luggin has an interesting little Paper on the effect produced by dividing an electrolytic cell into two portions by a thin metallic membrane. In opposition to Arons, he proves that they do not take any part in transmitting the current. The apparent resistance of half a square centimetre of a gold membrane goes into 1,000 ohms, and the natural conclusion is that the current is conducted by pores in the sheet, whose aggregate area need not exceed a few millionths of a square millimetre.——Paul Czermak discusses the use of very fine thermo-elements in meteorology. These have the advantage of taking up the temperature of the surrounding air with great readiness. The wires should be 0·1mm. thick and attached to stout copper tubes filled with water. A "relative actinometer" constructed on these lines will indicate hundredths of degrees, and will gauge the varying thickness of a fleecy cloud.——Holborn and Wien are continuing their high temperature work at the Reichsanstalt. They are working with a new kind of porcelain which is exceedingly refractory. A thermo-couple made of two different rhodium-platinum alloys is introduced into the oven under an inverted magnesia crucible, and gives the melting point of platinum as 178°C.——A. Oberbeck investigates the evolving effect of air currents of known velocity upon a platinum wire carrying a current. The temperature is measured by the change of resistance of the platinum. Conversely, an anemometer can be constructed on the same principle. Here is Prof. Langley's opportunity of proving his dictum that all winds proceed in puffs.

ELECTROMAGNETIC THEORY.—LXXVIII.*

BY OLIVER HEAVISIDE.

(*Continued from page 36.*)

§ 308. If there is no impressed force, but the middle cable is initially charged arbitrarily instead, there is a similar curious limiting case when the terminal cable Z_0 and the middle cable are equivalent. The general solution (100), through (110), reduces to

$$V_1 = \sin s(y+l)\frac{\sin sx}{\sin sl}\frac{sQ}{S}, \qquad (172)$$

indicating the potential at x, on the right of y, due to Q initially at y. When on the left side, interchange x and y to get the formula. The Z_0 operator is $(R/s)\tan sl$, as in § 306.

Developing by the expansion theorem, according to the roots of $\sin sl = 0$, and denoting the result by U, we obtain

$$U = \frac{2Q}{Sl}\Sigma \sin sy \sin sx\, \epsilon^{pt}. \qquad (173)$$

Now this is exactly the same as if the cable were earthed at $x=0$ and l. See (22), § 267, for example.

But the latent auxiliary normal functions, which we know to exist in general, have not been considered. The conclusion from the above result is, therefore, that in the complete expansion of the initial state, the sum of all the extra terms is zero. Only when t is finite can they be quantitatively existent in the total. They may be infinite then, should the p in ϵ^{pt} be infinite for the extra terms; but that is of no consequence as regards the initial state.

To verify the above, we may proceed as in § 307. Let Z_0 be not equivalent to the middle cable in the first place. Then Z_0 is as in (157), and Z_1 is its negative. The general equation (110) is now

$$V_1 = -\frac{(c\sin + \tan s_0 l_0 \cos)sy\,(c\sin - \tan s_0 l_0 \cos)s(l-x)}{(c^2+\tan^2 s_0 l_0)\sin sl}\frac{sQ}{S} \qquad (174)$$

instead of (172) above.

Developing this by the expansion theorem, let U be the regular part, and W the extra part. Then we get

$$U = \frac{2Q}{Sl}\sum \frac{(c\sin + \tan s_0 l_0 \cos)sy\,.\,(c\sin + \tan s_0 l_0 \cos)sx}{c^2+\tan^2 s_0 l_0}\epsilon^{pt}, \qquad (175)$$

in which $\sin sl = 0$, or $sl = \pi$, 2π, &c. And, in addition,

$$W = \frac{Q}{S}\Sigma \frac{c\epsilon^{q(x+y-l)}\epsilon^{pt}}{(1-c^2)q_0 l_0 \operatorname{shin} ql}, \qquad (176)$$

the notation being as in § 307, equations (161) or (163) finding the values of q_0. The unit impulsive function is the sum of U and W, with $t=0$, and $Q/S = 1$. The U part subsides to equilibrium, whilst the W part increases with the time.

Simplify by taking $f=1$, making $RSl^2 = R_0 S_0 l_0^2$, and $ql = q_0 l_0$. The unit impulsive function becomes

$$u = \frac{2}{l}\Sigma \sin sy \sin sx + \Sigma \frac{c}{l(1-c^2)}\frac{\epsilon^{q(x+y)}}{\epsilon^{q_0 l_0}\operatorname{shin} q_0 l_0}. \qquad (177)$$

Here the first part expresses the unit function concentrated at the point $x=y$, with repetitions outside the limits concerned, which do not count. We conclude that the rest represents zero between the same limits. The verification is easy, because the simplification made by assuming $f=1$ allows of the reduction of the extra part to a recognisable form. The extra part of u, say u_2, is

$$u_2 = \frac{1}{l(1+c)}\Sigma \exp\left\{(\lambda + in\pi)\frac{x+y}{l}\right\}, \qquad (178)$$

where n has all integral values, positive, negative, and zero. Or, which is the same,

$$u_2 = \frac{\epsilon^{\lambda(x+y)/l}}{l(1+c)}\left\{1 + 2\Sigma_1^\infty \cos\frac{n\pi}{l}(x+y)\right\}. \qquad (179)$$

This, by § 271, represents a row of impulses (not of unit size) outside the limits in question. Within the limits, therefore, u_2 is zero, as required.

Let u become v when t is finite. Then

$$v_1 = \frac{2}{l}\Sigma_1^\infty \sin\frac{n\pi y}{l}\sin\frac{n\pi x}{l}\epsilon^{-Ht}, \qquad (180)$$

where H is $n^2\pi^2/RSl^2$, and the summation is with respect to n. And for the extras, we have

$$\epsilon^{q(x+y)}\epsilon^{pt} = \exp\left\{(\lambda + in\pi)\frac{x+y}{l} + \frac{t}{RSl^2}(\lambda^2 - n^2\pi^2 + 2in\pi\lambda)\right\}, \qquad (181)$$

which makes

$$v_2 = \frac{\epsilon^F}{l(1+c)}\left\{1 + 2\Sigma_1^\infty \cos n\pi G\,.\,\epsilon^{-Ht}\right\}, \qquad (182)$$

where H is as before, and, for brevity, additional letters F, G are introduced, given by

$$F = \frac{\lambda(x+y)}{l} + \frac{\lambda^2 t}{RSl^2}, \qquad G = \frac{x+y}{l} + \frac{2\lambda t}{RSl^2}. \qquad (183)$$

Whilst v_1 subsides to zero, v_2 augments. In the singular case of failure, real or apparent, which occurs when $c=1$, the extra part v_2 jumps from zero to infiniteness instantly.

§ 309. Returning now to real electrical conditions, one of the minor matters that remains to be considered is the influence of the terminal arrangements on the state of the cable, when they are initially energised. The existence of auxiliary functions, one for every independent kind of energisation, has been pointed out. Also how, by means of the conjugate property of complete normal systems, their size may be determined. But the example given in § 295, relating to a terminal condenser, and the later examples, were not sufficiently general to illustrate the matter fully. So now take some other arrangements.

Say the $x=l$ end of the cable is earthed. Then $Z_1 = 0$, and,

$$v_1 = -\sin s(l-x)\frac{(R\sin + Z_0 s\cos)sy}{(R\sin + Z_0 s\cos)sl}\frac{sQ}{S} \qquad (184)$$

is the potential at $x\,(>y)$ due to Q at y. Interchanging x and y makes the potential at $x\,(<y)$ due to Q at y. Differentiating the new expression with respect to x and dividing by $-R$ produces the expression for the current on the left side of y. Put $x=0$ in it. The result is

$$C_0 = \frac{\sin s(l-y)}{(R\sin + Z_0 s\cos)sl}\frac{s^2 Q}{S}. \qquad (185)$$

This is, therefore, the total current in Z_0 due to Q, reckoned from left to right.

We conclude, by reciprocity, that a current momentarily established in Z_0 will produce potential at y, determined by the same operator as is concerned in (186), when there is magnetic inertia in Z_0. This is easily corroborated. Put an impressed voltage e at $x=0$. The C due to it, on the spot, that is, in Z_0, is

$$C = \frac{e}{Z_0 + (R/s)\tan sl} = \frac{e}{Z} \text{ say}, \qquad (186)$$

because the denominator is the sum of the resistance operators to right and left of e. This expands, when e is steady, to

$$C = \Sigma \frac{e\epsilon^{pt}}{p\dfrac{dZ}{dp}}, \qquad (187)$$

ranging over the roots of $Z=0$.

But let e be impulsive, say $= pL_0C_0$, so that L_0C_0 is the momentum generated. Then

$$C = \frac{p}{Z}L_0C_0 = L_0C_0\Sigma\frac{\epsilon^{pt}}{dZ/dp}. \qquad (188)$$

Putting $t=0$ makes the initial state. So

$$C_0 = \Sigma\frac{L_0C_0}{dZ/dp} \qquad (189)$$

must be the expansion of C_0, regarded as initially given to be the current in Z_0.

Also, the potential at x due to e is got by putting L_0pC_0 for e in (59), and $Z_1 = 0$. This makes

$$V = \frac{p\sin s(l-x)}{(Zs/R)\cos sl}L_0C_0, \qquad (190)$$

* This series of articles is a portion of Vol. II. of Mr. Heaviside's work on "Electromagnetic Theory." All rights of reproduction are reserved.

Digitized by Google

operationally, or

$$V=\Sigma\frac{L_0C_0R\sin s(l-x)}{\cos sl\,(dZ/dp)}\epsilon^{pt}, \qquad (191)$$

by the expansion theorem. From this, again, (189) may be derived. It will be convenient to consider Z_0 to be R_0+L_0p in the above, meaning a coil of resistance R_0 and inductance L_0. At the initial moment, therefore, (191) is the zero expansion required to suit the case of an energised coil, an expansion in a Fourier series representing zero within the limits, such that V shows what it becomes at time t later, as the coil discharges itself into the cable.

Next consider the same matter from another point of view, viz., that of independent normal systems. Put

$$v=\sin s(l-x), \qquad c=\frac{s}{R}\cos s(l-x). \qquad (192)$$

Since $v=0$ at $x=l$, these are the proper normal functions for V and C in the cable, provided s is suitably determined to satisfy $v/c=-Z_0$ at $x=0$. That is,

$$Z_0+\frac{R}{s}\tan sl=0=Z \qquad (193)$$

is the determinantal equation. Provided, then, we include every possible normal system subject to the last equations, we see that the initial state is fully specifiable by

$$V_0=\Sigma Av=\Sigma A\sin s(l-x), \qquad (194)$$

$$C_0=\Sigma Ac=\Sigma A\frac{s}{R}\cos sl, \qquad (195)$$

where A is a constant. Given V_0 and C_0, the conjugate property finds A. That property asserts that

$$S\int_0^l v_mv_n dx-L_0c_mc_n=0, \qquad (196)$$

where v_m, v_n are any two normal systems of potential, and c_m, c_n the currents to match at $x=0$, because there is magnetic energy in the coil, and electric in the cable. It follows that

$$A=\frac{S\int V_0v dx-L_0C_0c}{S\int v^2dx-L_0c^2} \qquad (197)$$

finds the coefficient A belonging to any system v, c when V_0 is given as a function of x, and C_0 has any value we like.

Attending only to the part dependent upon C_0, the result is

$$A=\frac{-L_0C_0\frac{s}{R}\cos sl}{S\left(\frac{l}{2}-\frac{\sin 2sl}{4s}\right)-L_0\left(\frac{s}{R}\cos sl\right)^2}, \qquad (198)$$

which, used in (194), completes the solution so far as C_0 is concerned, since the state at time t is deducible by the introduction of the time factor. It will be found that the solution thus got agrees with the former one, viz. (191), on expanding dZ/dp. Also, that (195) agrees with (189). As regards the conjugate property (196) which has been used, its proof is to be found in testing that it is true, when the proper expressions for v and c are used. This remark applies in all expansions in normal functions. I shall, however, give later a general proof of the property.

In the numerical execution of the above case, it may be as well to remark that there is sometimes a pair of imaginaries concerned in the determinantal equation, which might be overlooked, if we merely drew the curves

$$y_1=\tan sl, \quad y_2=(-s/R)Z_0, \qquad (199)$$

and determined the roots by their intersections.

§ 310. Now take a case in which both kinds of terminal energy are concerned. Say

$$Z_0=R_0+L_0p+\frac{1}{S_0p}, \quad Z_1=0, \qquad (200)$$

so that there are a coil and a condenser in sequence at $x=0$. The determinantal equation is

$$Z=0=\frac{R}{s}\tan sl+R_0+L_0p+\frac{1}{S_0p}, \qquad (201)$$

where $p=-s^2/RS$, as usual. Taking the normal functions as before, equation (192), the current at $x=0$ is the current in the coil. Therefore (195) is the expression for one of the terminal arbitraries—viz., the initial current in the coil. The other arbitrary is the charge (or the potential) of the condenser. Say that the condenser is next the earth, and that its potential is v_1 in a normal system and V_1 altogether. We have

$$v_1-v=(R_0+L_0p)c, \qquad (202)$$

where v and c belong to the terminal of the cable, and also

$$v_1=-\frac{c}{S_0p}, \qquad (203)$$

these being the equations of voltage for the coil and condenser respectively. So

$$v_1=\sin sl+(R_0+L_0p)\frac{s}{R}\cos sl \qquad (204)$$

is the normal function for v_1. This may, by (201), be simplified to

$$v_1=\frac{S}{S_0s}\cos sl. \qquad (205)$$

The initial state is therefore fully expressible by

$$V_0=\Sigma Av, \qquad C_0=\Sigma Ac, \qquad V_1=\Sigma Av_1, \qquad (206)$$

where A is a constant, the same constant for every three connected functions, but differing in the different complete systems. Given, then, V_0 as a function of x, and C_0 and V_1 arbitrarily, we evaluate any coefficient A by

$$A=\frac{S\int V_0v dx+S_0V_1v_1-L_0C_0c}{S\int v^2dx+S_0v_1^2-L_0c^2}, \qquad (207)$$

because the conjugate property is

$$0=S\int v_mv_n dx+S_0v_{1m}v_{1n}-L_0c_mc_n, \qquad (208)$$

the terminal energies being of different kinds. When $L_0=0$, the value of C_0 ceases to have any influence on the value of A, as we see by (207), although the expression

$$C_0=\Sigma Ac\,\epsilon^{pt} \qquad (209)$$

remains in force, for any finite value of the time.

§ 311. If the condenser and the coil are in parallel, the case is somewhat different. We now have

$$Z=0=\frac{R}{S}\tan sl+\left(S_0p+\frac{1}{R_0+L_0p}\right)^{-1}, \qquad (210)$$

because the resistance operator Z_0 is the reciprocal of the sum of the reciprocals of the resistance operators of the coil and condenser; or the conductance operator is the sum of the separate conductance operators.

The potential v at the terminal of the cable in a normal system is the potential v_1 of the condenser, so

$$V_1=\Sigma Av=\Sigma A\sin sl \qquad (211)$$

expresses one of the terminal arbitraries.

But only a part of the cable current enters the coil, so it is not the full current c that is concerned in the other arbitrary. We have

$$c_0=-\frac{v}{R_0+L_0p}, \qquad (212)$$

if c_0 is the proper function to associate with v. Therefore

$$C_0=-\Sigma\frac{A\sin sl}{R_0+L_0p} \qquad (213)$$

is the expression for the current in the coil initially.

But to determine A to suit the initial circumstances, we may still use the formula (207), taking care, however, to use the proper expressions of the present case for v, v_1 and c. The last has now become the c_0 in (212), whilst v_1 is to be the v in (211).

§ 312. If the terminal arrangement consists of two coils in sequence, there is but one auxiliary function, because the current is constrained to be the same in both coils. Suppose e is an impressed voltage, and there is mutual inductance m between the coils r_1, l_1 and r_2, l_2. The equation of voltage is

$$e=(r_1+l_1p)c_1+mpc_2+(r_2+l_2p)c_2+mpc_1, \qquad (214)$$

where c_1 and c_2 are the currents. Both being equal to c, say, this reduces to

$$e=(r_1+r_2)c+(l_1+l_2+2m)pc, \qquad (215)$$

the same as for a single coil. So there is nothing new here.

Digitized by Google

But if the coils are in parallel, there are two arbitraries. For we shall now have

$$e=(r_1+l_1p)c_1+mpc_2, \quad (216)$$

$$e=(r_2+l_2p)c_2+mpc_1; \quad (217)$$

from which the resistance operator of the combinations and the separate ones have to be deduced. Solve for the currents thus:—

$$\frac{c_1}{e}=\frac{(r_2+l_2p)-mp}{(r_1+l_1p)(r_2+l_2p)-m^2p^2}, \quad \frac{c_2}{e}=\frac{(r_1+l_1p)-mp}{(r_1+l_1p)(r_2+l_2p)-m^2p^2}. \quad (218)$$

These are the conductance operators separately. Their sum is the conductance operator of the combination. Its reciprocal is the resistance operator. Therefore

$$Z_0=\frac{(r_1+l_1p)(r_2+l_2p)-m^2p^2}{r_1+r_2+(l_1+l_2-2m)p} \quad (219)$$

is the required Z_0, to be used in the determinantal equation. Also, the previous equations for c_1 and c_2 give the proper normal functions for them in terms of e, which becomes $-v$, the normal function for the potential at the cable end. Thus determined, the two arbitraries are ΣAc_1 and ΣAc_2, to be associated with ΣAv, expressing the potential in the cable.

In determining A by the conjugate property, m must not be forgotten. Twice the energy of c_1 and c_2 is

$$l_1c_1^2+l_2c_2^2+2mc_1c_2=F, \text{ say,} \quad (220)$$

or

$$(lc_1+mc_2)c_1+(lc_2+mc_1)c_2; \quad (221)$$

and the mutual energy of C_1, C_2 and c_1, c_2 is

$$(lc_1+mc_2)C_1+(lc_2+mc_1)C_2=G, \text{ say.} \quad (222)$$

Consequently, given V_0 along the cable, and also the values of C_0 and C_1 initially, the value of A is

$$A=\frac{S\int V_0v\,dx-G}{S\int v^2dx-F}, \quad (223)$$

which renders the solution of the problem complete, when the normal potential function v for the cable is properly determined to suit Z_0, as in (218). The principle underlying these determinations is quite a simple one, and may be applied to the most complicated cases.

(To be continued.)

COVENTRY AND DISTRICT ELECTRIC TRAMWAYS.

It is now more than two years since the cessation of the steam tramways in Coventry. Prior to the starting of those trams a name had already been won for itself by Coventry in the annals of tramway traction, for it was over identically the same route as the present six-mile electric line between that town and Bedworth that, so long ago as 1811, a stone tramway had been built, this now antiquated pattern of line then extending from Coventry to Nuneaton. The subsequent steam tramways need not concern us much, except that the present rails were formerly laid for that system, and that a very small portion of the old steam plant has been retained for use at the electric generating station. It is little, if any, wonder that the steam-driven cars should have gone out of existence; and it is greatly to be hoped, if not reasonably to be expected, that their failure arose from their inherent defects, and not from local conditions of traffic. Rarely, indeed, can a line of tramways come into existence that does not put itself into competition with, and find a serious competitor in, some existing method or methods of locomotion. Usually it is a line of 'buses, or a railway, or the poverty which makes people walk; but at Coventry it is little of these by comparison with the bicycle and the tricycle. In that district almost everyone, without distinction of age or sex, is a devotee of the wheel; and, after traversing the route and noting the conditions, we feel sure that it is the cycle which will be the most serious competitor with the electric line shortly to be put in operation between Coventry and the suburban semi-rural districts extending to Foleshill and Bedworth.

At the present time the whole of the generating house and the car sheds are equipped and in working order, the six miles of track are almost completely equipped with the trolley poles, conductors, &c., and four of the old cars have been converted into motor cars, four new motor cars have been built, while two of the old cars have been fitted up as trailers, for use on market days and in times of excessive traffic. The inspection by the Board of Trade is now impending, and the line will be opened for traffic immediately after the sanction of that authority has been obtained.

From the earliest stage it had been intended to adopt the overhead trolley system, and in May last it was definitely decided to have the Westinghouse system, the contract for the electrical and generating plant and equipment being given to the General Traction Company, of Westminster.

The style of construction adopted by these contractors very closely follows the American model, differing from it only where this is made necessary by the regulations of the Board of Trade; and a considerable portion of the plant has been made in the United States. The generating station, with adjoining car sheds, is situated at Foleshill, about mid-way between the termini of the line. It is a substantial brick structure, of airy proportions and well lighted, by means of skylights and windows in the daytime and by inverted arcs and numerous glow lamps at night. The ground plan of the various rooms is shown in Fig. 1, and this drawing also shows the position of the plant. The boiler house, the floor of which is 3ft. below the level of the engine-room floor, contains two Babcock-Wilcox boilers, each capable of developing steam for about 100 H.P. These boilers are mechanically stoked by two Babcock-Wilcox automatic coking stokers, which are driven by a small Sturtevant vertical steam engine in the machinery room. This engine also drives a countershaft, from which a number of machine tools obtain power. Feed water is derived from a neighbouring canal, and is pumped into the station by a Worthington and a Hatton steam pump, the latter having been used formerly for raising water for the steam locomotives.

Ascending a short flight of steps, we pass into the machinery room. The equipment of this room has been arranged with a view to minimise the costs of attendance and superintendence; and with the same object in view, each detail of the plant has been solidly and simply built, so as to be capable of being run by an ordinary mechanic. To this end, the machine tools for the repairs, the auxiliary machinery and the store room have all been brought into the machinery room, and are all exposed to the view of one man in charge. Further to simplify attendance, each of the two traction power generators (but not the smaller dynamo for lighting) is surmounted by six pilot lamps connected in series to the brushes of the machine. The purpose of these seems to be to minimise the need for looking at the voltmeters on the switchboard.

There are two sets of generators for the tramcar service, each of which is capable of taking the ordinary load. Each set comprises a single cylinder, horizontal, non-condensing steam engine, built by Messrs. Browett and Lindley, belt-coupled to a 4-pole Westinghouse railway generator. Fig. 2 shows the general construction of the steam engines, the most striking feature in which is the two heavy flywheels on opposite ends of the crankshaft. This unusually massive construction is designed to enable the engines to take the excessive and momentary rises in load, which are a peculiarity of traction station work; and they are rendered necessary by the fact of there being no electrical storage plant. Changes of load are, however, also taken by the steam, the engine being provided with a prompt automatic cut-off governor, which will give steam on occasion up to half-stroke. The normal and most economical load is at quarter-stroke cut-off, and at this each engine develops about 120 H.P. The cylinders are 13in. in diameter, and the stroke is 13in. The normal steam pressure is about 100lb. At half-stroke cut-off, about 150 H.P. will be developed by each engine. An exhaust-steam feed heater stands beside the engines, after passing through which the exhaust steam is discharged through a pipe outside the building. Fig. 3 shows the type of railway generator used. Each of the two machines of this type is built to develop 200

Digitized by Google

amperes at 500 volts, when running at 625 revolutions. The machines are provided with ironclad armatures, and carbon brushes are used. In addition to these two generators, there is a 5-kilowatt Immisch 100-volt dynamo, driven by a Sturtevant vertical steam engine, for the inverted arcs in the machinery room and car sheds, and for the glow lamps which are not used as pilot lamps.

at the bottom, and a Weston station voltmeter, which now has been placed in the top row. The top row includes two gravity ammeters for the generators; in the second row are the automatic circuit-breakers and a gravity station ammeter; and below are the switches, regulators and recording voltmeters.

Eight motor cars and two trailers will constitute the rolling stock. The motor cars are carried upon Peckham cantilever

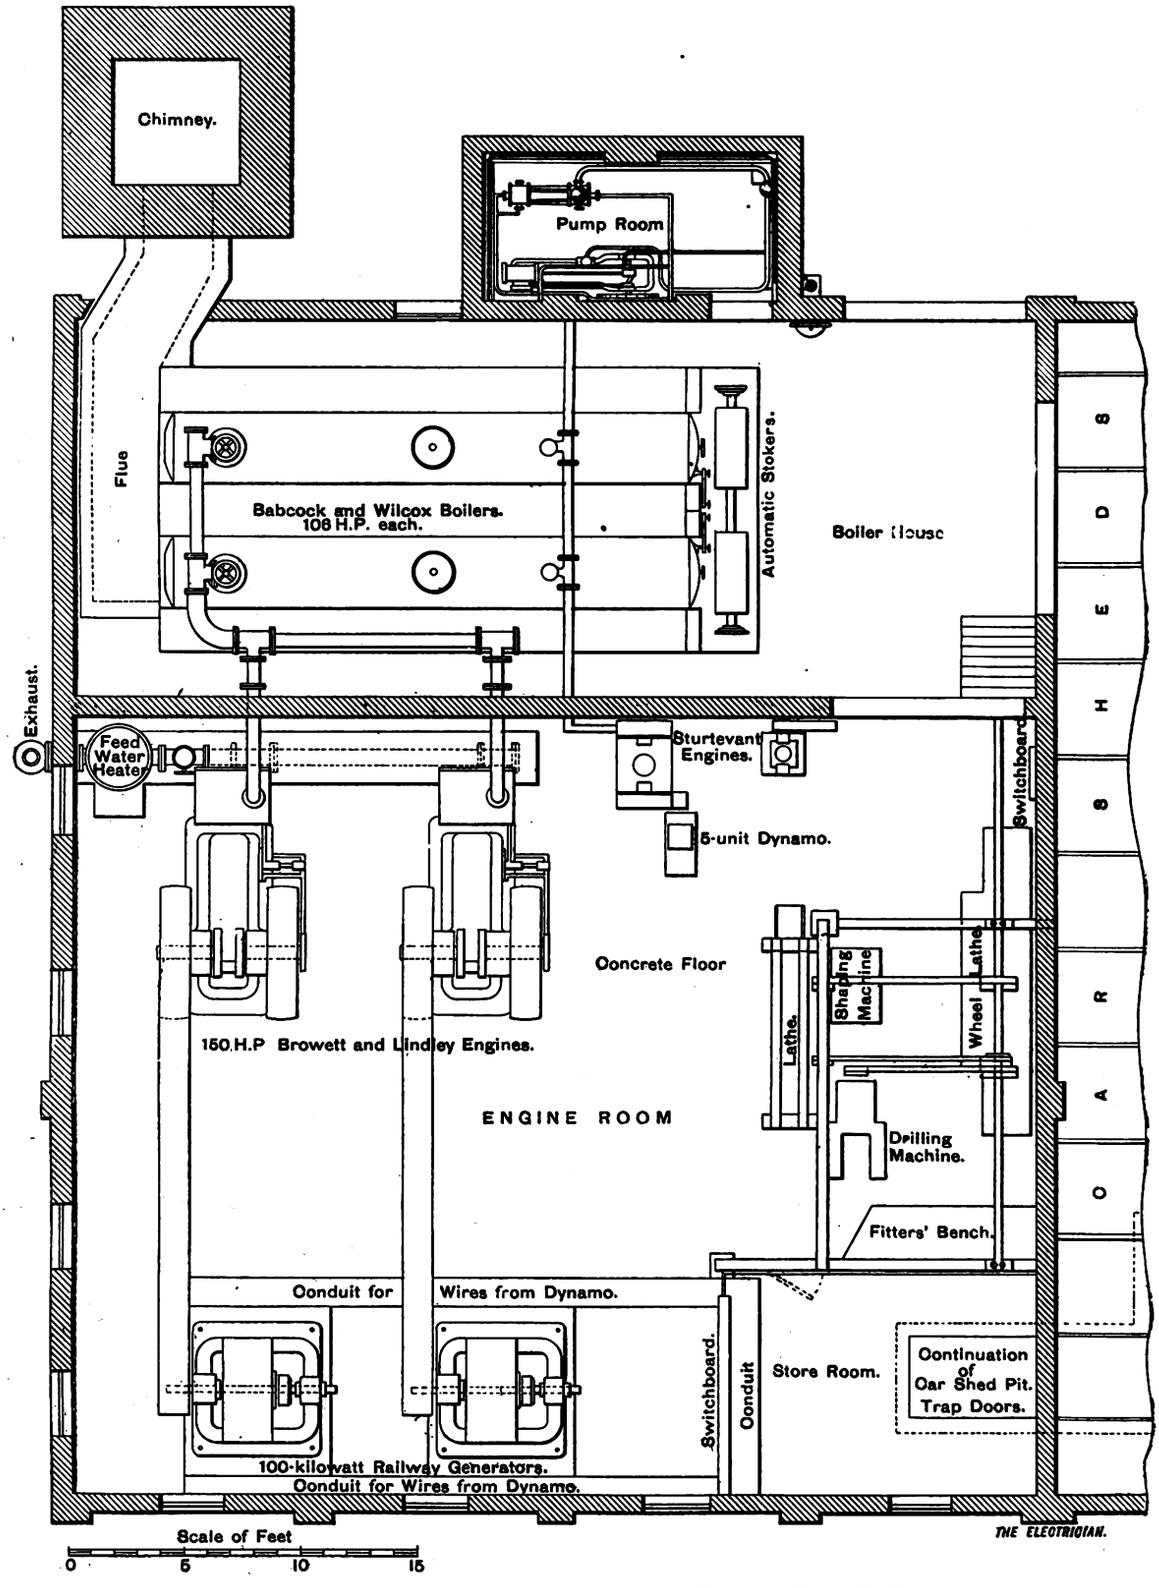

FIG. 1.—Plan of Coventry and District Electric Tramways Power Station.

The switchboard for the traction generators is built into one side of the iron-framed store room, and all the instruments are mounted on white marble slabs. Fig. 4 shows the switchboard equipment, with the exception of the two earth-current indicators, which will shortly be placed on the two vacant panels

trucks, of American manufacture, a view of one of which is shown in Fig. 5. Each truck is fitted with two 4-pole Westinghouse motors of the No. 12 type, each motor being built for a maximum load of 25 H.P. The 4-pole arrangement permits of the two brushes being placed near the top of the commu-

tator (at 90deg. apart); and ready access to these is gained through a trap-door in the car floor, and by lifting a flap on the motor cover. The motors are geared by single reduction, oil-boxed, spur gear to the truck axles, the gear being of cut steel. A reduction ratio of 4·68 is obtained with the gear. A series-parallel controller is placed on the platform at each end of the car. In addition, the platform is equipped with a hand-ratchet brake, and with a foot-gong. Each car carries 11 glow lamps of 16 c.p. each, but 10 of which will be lit simultaneously. The lamps in use at any time will be coupled in sets of five in series across the trolley circuit. It has been found both in America and in this country that the plentiful illumination always to be found in trolley cars is a strong

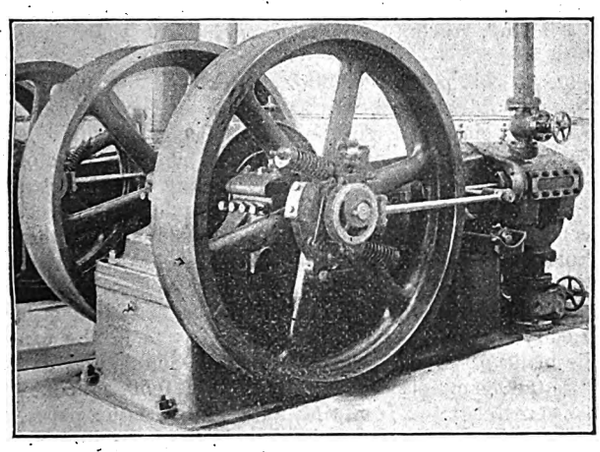

FIG. 2.—Coventry Electric Tramways. Browett-Lindley Engine.

inducement to ride in them; and in more than one place passengers are in the habit of changing from the 'bus to the trolley car at the starting-place of the latter. The Coventry cars carry four glow lamps for the deck passengers. The capacity of the new cars is 40 passengers; but the converted cars and the trailers will take 50 persons each.

The main portion of the route is of single track; but there are no less than 27 turn-outs, some of considerable length. The general character of the route may be described as undulating, with no very sharp curves, but with several steep

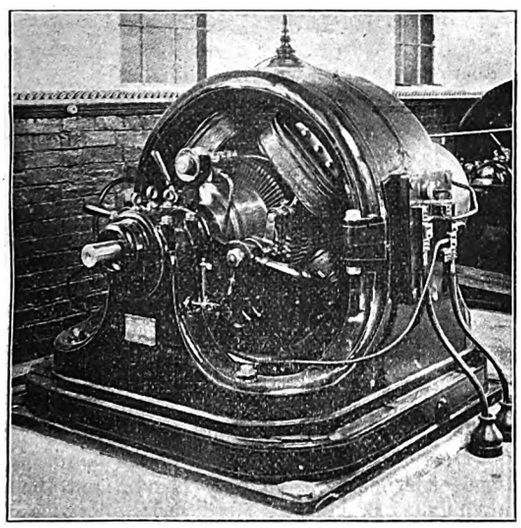

FIG. 3.—Coventry Electric Tramways. Westinghouse Dynamo.

gradients, the maximum gradient being 1 in 16. The old rails throughout have been retained, and have been bonded on the Chicago plan. There are no special cross-connections, as the bonds at the numerous turn-outs sufficiently answer the purpose. With so many turn-outs in no more than six miles of track, it has been decided to duplicate the trolley line almost throughout its length, instead of putting a frog at the in-turn and out-turn of each passing place. The object has been to save the time which would otherwise be wasted in passing the frogs, owing to the necessity for going slowly under such a device. The trolley wires are mainly held in position by means of span wires, from which they depend, and to which they are attached by "Ætna" insulator hangers. Along the country roads the span wires are fixed to steel poles, which are placed along both sides of the vehicular way at intervals of about 50ft. In the

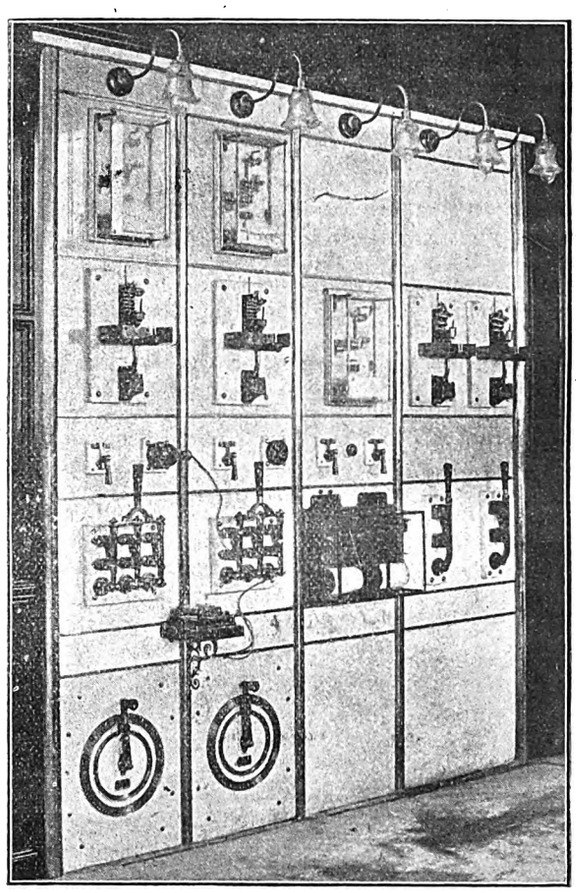

FIG. 4.—Coventry Electric Tramways. Switchboard.

narrower streets of the town these poles have been dispensed with, and the span wires are attached to insulated wall-plugs. Each of these plugs is provided with an india-rubber pad or cushion for silencing the noise of the trolleys. Over a comparatively short portion of the route, at the Coventry end, a single trolley wire, supported by single brackets on steel poles,

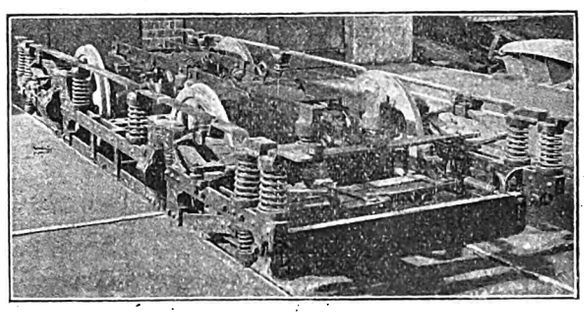

FIG. 5.—Coventry Electric Tramways. Motor Truck.

is used. The feeder for the sections of the line—these sections being in half-mile lengths—is, over the greater part of the route, carried on the tops of one line of poles, but in the narrower and busier streets of the town it is placed underground.

Our thanks are due to Mr. J. E. Winslow, the chief engineer to the General Traction Company, and to Mr. H. Lavington Fletcher, the resident engineer in charge of the construction work, for their kindness in placing information and photographs, &c., at our disposal.

THE HYSTERESIS OF IRON IN AN ALTERNATING MAGNETIC FIELD.*

BY FRANCIS G. BAILY, M.A., A.M.I.E.E.

The hysteresis of iron, when exposed to an alternating field of magnetic force, shows at low induction a continuously increasing value, which has been stated by Mr. Steinmetz to be approximately proportional to the 1·6th power of the induction. The more accurate experiments of Prof. Ewing by his ballistic method show that this expression can be taken only as giving a general average over a part of the curve, and not as an accurate interpretation of the true function. But the ballistic method of testing iron arranged in the form of a continuously-wound ring, though very accurate, does not permit of the use of high magnetising forces, and falls far short of the saturation of the iron.

From a consideration of the theory of the cause of hysteresis, it seems probable that there will be no hysteresis in those changes of induction during which the iron is completely in the saturated condition, since the molecules are maintained rigidly in one position throughout. Therefore the hysteresis loss in a complete cycle, when slowly performed, will reach a maximum value at which it will remain constant for all values of the induction above that of saturation. Thus, in Fig. 1, if A is the point beyond which the iron is saturated, the area of the closed curve gives the maximum value of the hysteresis, and increase of the induction to B or beyond will not result in any change in the hysteresis. This point has not been proved experimentally, but there can be little ground for doubting it.

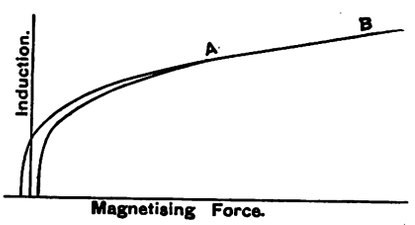

FIG. 1.—Hysteresis Curve with High Magnetising Force.

When the iron is placed in a rapidly alternating field, at a speed comparable with that of commercial alternating currents, the conditions are somewhat different. In such a magnetic field the induction will pass through alternately reversed maximum values, and as the magnetising forces are increased beyond the point of saturation the intensity of magnetisation will stay constant at its saturation value for a gradually increasing portion of each half-cycle. Hence the slope of the curve representing the change of magnetisation will become steeper at the two ends, the rate of change of magnetisation becoming greater.

At slow speeds the hysteresis, as stated above, is probably constant, but at high speeds it is possible that the increase in the rapidity of motion of the molecules may increase the energy of their vibrations as they swing into new combinations, and hence the hysteresis will be increased notwithstanding the saturation. The point depends on the effect of speed on hysteresis, which has not been very fully worked out. Experiments on soft-iron wires by Tanakadaté (*Phil. Mag.*, 1889), though not rigidly accurate, tend to show that up to 400 cycles per second the hysteresis per cycle is practically unchanged, and experiments of the author's, not yet published, confirm the result. The work of Steinmetz and of A. Siemens, in which a different result was obtained, does not seem reliable on this question, some of the results of the former experimenter being contradictory. If the problem is considered from a theoretical point of view, it seems probable that there will be very little, if any, change due to speed in hysteresis for a given value of the induction. Experiments with exceedingly rapid alternations show that iron molecules respond with great facility to rapid changes of field, and that the molecules exert a mutual action producing hysteresis. The time lag of magnetisation is therefore very small in the magnitude of its effect, although other experiments show that it is not small in the duration of its time of action. Moreover, the time of vibration of these molecular magnets must be enormously higher than a few hundreds per second, and hence nothing of the nature of synchronism can occur. Therefore the vibration caused by each cycle will be transmitted to neighbouring particles, or, in other words, disseminated as heat before the commencement of the next cycle, and changes in the speed of alternation, being of a different order of magnitude to the vibrations of the molecules, will be without sensible influence on them. On this view the same law of hysteresis should hold in a rapidly alternating field as in one of very slow change, and the curve of hysteresis and induction should show a flexure, reaching a maximum, and after that remaining constant.

To prove this point the following experiments were undertaken. In order to obtain a strong field the "isthmus" method was employed, the hysteresis being measured calorimetrically by the rise in temperature in a given time of the sample of iron under test in an alternating field of constant frequency. The apparatus consisted in a laminated iron electro-magnet built of soft charcoal iron sheets 0·25mm. in thickness, the pole-pieces being pyramid-shaped with flat ends, between which the sample was placed, as shown in Figs. 2, 3 and 4 The sample under test was very finely laminated in order to avoid eddy currents as far as possible. It was in the form of a cube made of 73 plates of thickness 0·085mm. and average breadth 0·808cm., giving a total area of 0·50 sq. cm. The plates were insulated from one another by tissue paper, the whole being soaked in shellac varnish, thus forming a solid cube. A single layer of silk tape covered the plates, and over this was wound a coil of 33 turns in a single layer. This was then covered with sheet cork $\frac{1}{16}$in. thick, and over this a second coil was wound of 22 turns. A second layer of cork was added, and the whole was coated with melted shellac. The two ends which had been left exposed were carefully faced, and a thin layer of cork was cemented on and coated with shellac. The section is shown in Fig. 5. The dimensions of the armature were as follows:—

Number of plates	= 73.
Thickness of plates	= 0·085mm.
Breadth of plates	= 0·808cm.
Area of iron	= 0·50 sq. cm.
Length of iron	= 0·9cm.
Size of wire in coils	= 0·12mm. diameter.
Number of turns in inner coil	= 33.
Area of inner coil	= 0·78 sq. cm.
Area of non-magnetic material	= 0·28 sq. cm.
Number of turns in outer coil	= 22.
Area of outer coil	= 1·61 sq. cm.

Difference of area of inner and outer coils = 0·83 sq. cm.

Between the inner layer of silk and the iron was placed a thermo-electric junction of a copper and German silver wire in contact with the iron.

The sample was placed in a small flat box, with ivory sides, against which the cork-protected ends of the sample abutted, and the box was then packed with cotton wool and placed between the poles of the electro-magnet. The armature was thus maintained always in the same condition, so that its capacity for heat remained the same throughout the experiments. The loss of heat from the sides of the sample was very small, as the experiment lasted only 1½min., and the rise in temperature did not exceed 25°C. Moreover, the cork lagging had a low specific heat and very low thermal conductivity, and the leading-in wires were extremely small. But it was found that at the ends, where the protective covering was thinner and was pressed against the pole-pieces, the transference of heat was too great to be neglected. In order to avoid this error the pole-pieces were maintained at the same temperature as the armature during the experiment by causing a stream of hot or cold paraffin oil to flow over the pole-pieces as required, the least difference of temperature being indicated by thermo-electric junctions in the pole-pieces connected to the one in the armature. By this means a very close agreement could be maintained, and any error caused was not always in the same

* Paper read before the British Association at Ipswich, Section A.

Digitized by Google

direction. A stream of cold paraffin was used to cool the apparatus between successive tests. By the use of paraffin oil as a cooling agent no precautions were required to prevent the liquid reaching the exciting coil, which was in fact immersed in a bath of the oil. The armature was protected by its box from any contact with the liquid.

The rise in temperature was measured by connecting the thermo-electric circuit to a d'Arsonval galvanometer, which being on closed circuit was dead-beat, and gave accurate and instantaneous readings. The alternating current was taken from a dynamo, the speed of alternation being kept constant at 103 periods per second. The maximum E.M.F. was 800 volts and the maximum current was 8·5 amperes. In performing the test, the current was turned on for 1½ minutes, and the increase of deflection of the galvanometer was read at the end, the rise in temperature of the pole-pieces and armature being kept equal during this time, as described above.

The determination of the maximum value of the induction was made by means of the search coils on the armature. In the coil

$$\text{Mean E.M.F} = 4\,(B_i A_i + B_a A_a)\,m\,n,$$

where B_i is the maximum value of the induction in the iron, A_i is the area of the iron, and $B_a A_a$ the values for the air

Electro-Magnet for Alternating Currents.

FIG. 2.—Side elevation, ¼ full size.

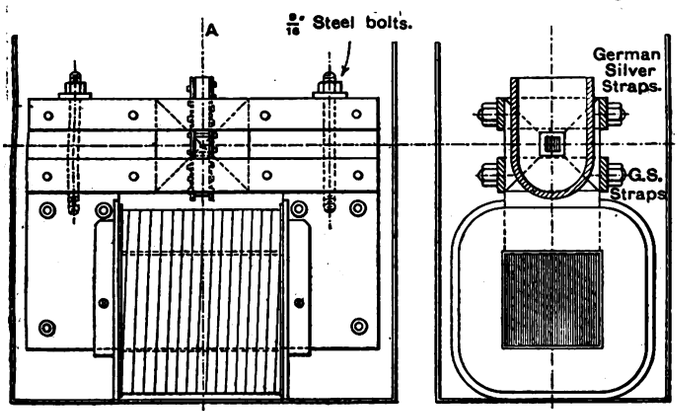

FIG. 4.—Plan of magnet.

FIG. 3.—Section through A.B.

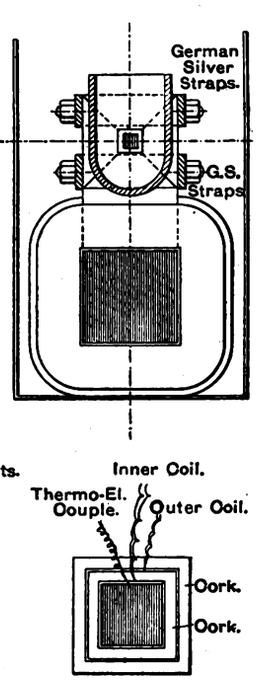

FIG. 5.—Section of armature. Full Size.

spaces, paper, &c. This is independent of the form of the curve dB/dt. Now in a circuit of large self-induction and small resistance, the counter E.M.F. follows almost exactly the impressed E.M.F., and the secondary E.M.F. induced in the search coils will also follow the same law. Hence their effects on a galvanometer will be the same and can be compared. By means of a soft iron-galvanometer, the current induced in the search coils through a known non-inductive resistance was compared to the current through a known non-inductive resistance from the terminals of one of the coils of the dynamo, the voltage of which was measured on a Cardew voltmeter. The E.M.F. curve of the dynamo was tested by the momentary contact method, and the ratio between the mean value of the E.M.F., and the square root of the mean square of the volts, as given by the voltmeter was calculated. It was found to be practically the same with different loads, so that the same constant could be used for all values of the current. The ratio was found to be 0·75, owing to the curve of the alternator being more peaked than the sinoidal form. In order to avoid any possible change in the galvanometer, each reading was calibrated immediately, by inserting resistances in the circuit from the alternator coil until the deflection was the same as that given by the search coil, the reading of the voltmeter being noted. By this method the E.M.F. induced in the search coil was compared directly with a known E.M.F. It is then easy to calculate the induction in the search coil.

If N is the total number of lines of force in the inner coil, N' is the total number of lines of force in the outer coil, R_1 R_1' are the resistances of the search-coil circuits, R_2 R_2' the resistances required to reduce the deflections of the dynamo coil to the values given by the search coils, V is the voltage of the alternator coil, m m' the windings of the search coils, and n the frequency, then

$$N = \frac{0{\cdot}75\,V\,10^8}{4\,n\,m\,R_2} R_1,$$

$$N' = \frac{0{\cdot}75\,V\,10^8}{4\,n\,m'\,R_2'} R_1';$$

and if A A′ are the areas of the coils, the magnetising force

$$H = \frac{N' - N}{A' - A},$$

and induction in iron

$$B = \frac{N - A_a H}{A_i},$$

where A_a A_i are the areas of air and iron in the inner coil. In the experiments R_1 and R_1' were always made qual.

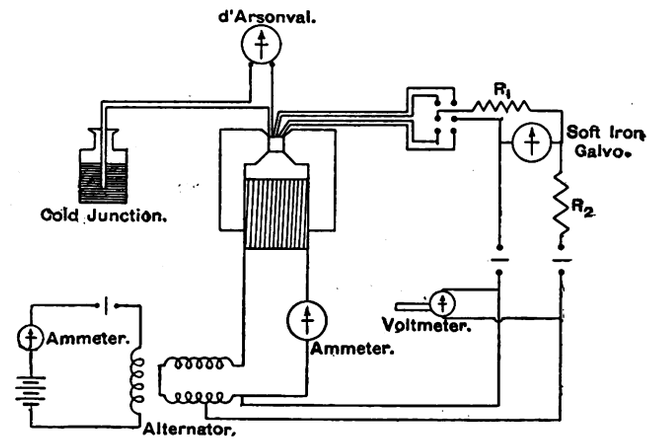

FIG. 6.—Diagram of Connections.

Owing to the change in the permeability of the iron the curves of dN/dt for the iron and the air will not be quite coincident, and this will introduce a small error in the estimation of the induction in the air. But as this only enters as a correction, the error in the value of the induction in the iron will be very small.

The galvanometer was a single-coil Thomson reflecting instrument of 10 ohms resistance and coefficient of self-induction $2{\cdot}24 \times 10^7$cm. The steel needle was replaced by a disc of soft iron placed at a small angle to the plane of the coil, so that the direction of motion was independent of the direction of the current. It carried the mirror, and was suspended by a fine platinum wire, which acted as the restoring force. A small aluminium vane, dipping in a bath of oil, damped the oscillations. With an additional 103 ohms in circuit, the impedance at 103 ∿ per second was 114 ohms. The galvanometer stood at a distance of 30ft. from the electro-magnet and 50ft. from the dynamo, so that it was quite free from all disturbances. All the leads from the armature to the galvanometer were very carefully stranded and insulated.

It may be of interest to mention that this galvanometer, though not of a form much in use, worked extremely well, giving very consistent readings when not touched, and being well adapted for the measurement of these small alternating currents. During each test readings were taken from each search coil, and calibrated from the dynamo coil.

In Fig. 6 is given a diagram of he connections with an enlarged diagram of the thermo-electri junctions in Fig. 7.

Digitized by Google

Double-pole keys allowed of the insertion in the soft-iron galvanometer circuit of each of the two search coils and the alternator coil respectively. A three-way key (Fig. 7) made connection to the junctions in either pole-piece, and finally to the cold junction for the reading of the rise in temperature at the end of 1½ minutes.

After some preliminary trials to ascertain the reliability of the readings and to improve various details of the apparatus, a series of readings was taken with different values of the E.M.F. up to the maximum obtainable from the dynamo, each point being identified by two or more experiments. No attempt was made to obtain readings at low induction, since this part of the curve has been frequently examined by other methods. Moreover, it was found that at low induction the rise in temperature of the pole-pieces was much below that of the armature, and hence it was difficult to keep a balance of temperature, whereas at high induction the two parts heated up almost exactly together, rendering the equalisation very easy. The E.M.F. was varied by inserting a greater or smaller number of alternate coils in series, thus keeping the curve of the alternator E.M.F. unchanged in form.

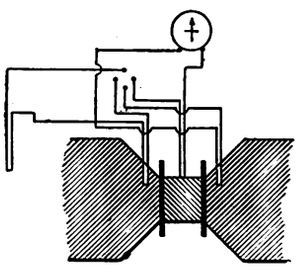

FIG. 7.—Thermo-Electric Junctions.

The differences in the values of R_2, R_2' and V in the same set of readings are caused by the fact that the winding of the magnetising coil was altered two or three times, and some of the repeated readings were made after the alterations. The calculated values of H and B were found to be in very close agreement.

The following table gives the readings and calculated results :—

—	R_1.	R_2.	R_2',	V.	Defl.	Mean values. N.	N'.	H.	B.	I.	Defl.
I.	114	9,900	13,400	116·0	5·0	7,700	8,200	600	15,400	1,180	6·0

	214	10,800	14,300	100·0	10·8						
	214	10,800	14,200	99·5	11·0						
V.	214	10,000	12,900	102·0	11·5	12,000	14.000	2,410	22,600	1,610	11·8
	214	10,000	12,900	101·5	12·0						
VI.	214	10,300	13,100	107·0	12·5	12,300	14,500	2,600	23,200	1,640	11·9
	214	10,400	13,300	109·0	11·5						
	214	10,700	14,000	111·0	13·0						
	214	10,700	13,800	111·5	12·0						
	214	10,700	13,700	111·0	11·5						
	214	10,800	13,800	112·0	11·0						

The results are plotted in Fig. 8, showing the relation between hysteresis and induction. In Fig. 9 is shown the relation between hysteresis and intensity of magnetisation, the latter being calculated from the expression $\mathsf{B} = \mathsf{H} + 4\pi\,\mathsf{I}$. It is probably not quite accurate, owing to the method of measuring H giving a somewhat excessive value for that quantity, but the general character of the curve is correct. The dotted portion of the curves are added from tests on another portion of the same sample of iron taken by the ballistic "return to maximum" method.

The results show clearly that there is a marked falling off in the rate of increase of the hysteresis as the saturation point is approached, the value at this point becoming practically constant. The calculated value of the intensity of magnetisation attained to is 1,640, a figure which is probably slightly below the real value. From Prof. Ewing's experiments the saturation value for soft iron is 1,660, so that the results are in good accordance.

The eddy currents have been neglected in the above curve, but a short calculation shows that they do not appreciably affect its shape. Taking J. J. Thomson's expression for eddy currents in thin plates in which the lines of force are in the plane of the plate, the power absorbed

$$= \frac{1{\cdot}67\,\mathsf{B}^2 n^2 t^2\, 10^{-16}}{\rho} \text{ watts},$$

where t is the thickness of the plate.

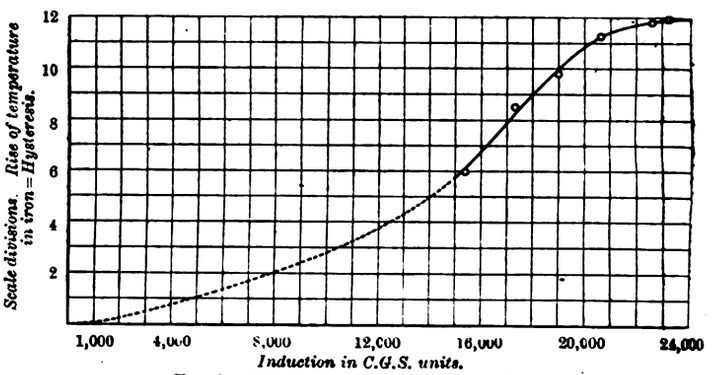

FIG. 8.—Hysteresis in Soft Charcoal Iron.
Alternating field, 103 ∿ per second.

The specific resistance of the sample was $1{\cdot}3 \times 10^{-5}$. Therefore the loss per cycle

$$= 1{\cdot}28\,\mathsf{B}^2\, n\, t^2\, 10^4 \text{ ergs},$$

where $\mathsf{B} = 23{,}200$, $n = 103$, $t = 0{\cdot}0085$cm.

$\mathsf{W} = 510$ ergs per cubic centimetre per cycle.

The maximum value of the hysteresis, calculated from the value obtained by the ballistic method, = 30,000 ergs approximately. Therefore the eddy-current loss at its maximum value is only 1·7 per cent. of the hysteresis loss, and is not greater than the unavoidable inaccuracies of the calorimeter method of measurement.

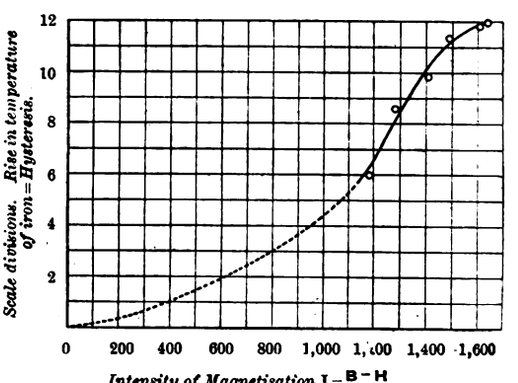

FIG. 9.—Hysteresis in Soft Charcoal Iron.
Alternating field, 103 ∿ per second.

With the dynamo power available, a further increase in the induction was not possible, but the author hopes to extend the experiment in order to obtain values of the hysteresis with induction beyond the saturation point, as it is possible that a small rise in the hysteresis may still occur.

The conclusion may, however, be drawn that the hysteresis in iron arrives substantially at a maximum when the iron becomes saturated, and that the function expressing the hysteresis in terms of the magnetic condition of the iron should depend not on induction, but on the intensity of magnetisation, with at most a small correction in terms of the former. The result accords well with Ewing's theory of magnetism, the third stage being very clearly marked. A reference to his Paper

Digitized by Google

(*Proc.* Roy. Soc., and *The Electrician*, April 13, 1894) shows, however, that even at comparatively low induction Ewing had identified three distinct parts in the curve, the middle one from $B = 2,000$ to 8,000 having the smallest rate of increase, while from 8,000 to 14,000 the rate of increase of hysteresis is slightly greater. If this is the case an additional stage must be added from 15,000 to 23,000, in which the rate of increase becomes rapidly smaller, the point of flexure being, as is seen, at about the value $B = 15,000$. It is probable that the latter is the true third stage corresponding to the condition of the iron above the knee of the induction curve, and that the two stages from $B = 2,000 - 14,000$ really are a single stage corresponding to the condition of high permeability.

The above experiments were carried out in the electrotechnical laboratory at University College, Liverpool. The best thanks of the author are due to one of his students, Mr. D. S. Mitchel, and to his assistant, Mr. E. H. Morgan, for their valuable help in the work, and also to Messrs. Knight and Crowther for their kindness in specially rolling the very thin iron plates used.

LOCAL ANNEALING OF HARD-FACED ARMOUR PLATES.*

BY HERMANN LEMP, JUN.

Everyone is now more or less familiar with the Thomson electric welding process, which in past years has been introduced in almost every metal industry in one shape or another. This process created a new field in the technical application of currents of large volume and small E.M.F., a field which, while it was primarily intended for welding, naturally suggested a number of other applications to so fertile an inventor as Prof. Thomson; and so it happened that early in its fundamental inception the use of large currents was contemplated to be utilised for heating plain metal bars or parts of sheet billets, &c., for forging purposes, to rivet, upset, to temper or withdraw the temper, or to be worked upon in any well-known manner while being kept heated by the current.

It has been the good fortune of the writer lately to work out one of these novel applications, and since the literature concerning this branch of electrotechnics is somewhat limited, he has thought it advisable to bring an account of the same before the Institute.

One of the latest advances in the making of protective armour for battle-ships, or even forts, has been the introduction of what is known as the Harvey process. For those not conversant with the latter, I will briefly state that it consists in taking an ordinary low carbon steel plate and introducing an additional percentage of carbon into the surface metal, thus changing the crust to the depth of about an inch, into a steel resembling tool steel. A plate thus treated, is lastly water-hardened, similarly to an ordinary tool, and by experience has shown to offer, under equal conditions, more resistance to the impact of a projectile than any other armour known. And therefore we will take this as an illustration of hard-faced armour. The extreme hardness of the surface of a Harvey plate, while exceedingly valuable in preventing projectiles from piercing it, has a disadvantage when it is required to be pierced by a drill and tap. Such holes may be required either for fastening ladders, swivels, or other appliances to the hull of the vessel, or to fasten T-flanges supporting the deck to barbettes or turrets.

The methods heretofore used to produce these holes were principally two:—

1. To protect the surface of the plate in patches or strips, to prevent carburation, wherever holes were expected to be drilled.

2. To make accurate drawings and patterns of each plate beforehand, to which all holes are drilled before plate is hardened.

Plan No. 1 was practised in the United States until it had to be abandoned. In practice it was found that numerous alterations in construction, errors in either draughting room or mills, made it necessary to pierce holes where no provisions for annealing were made. It also happened quite frequently that the method for prevention of carburation did not always work satisfactorily, and while white paint indicated well enough where soft metal was expected, very often hard metal was actually found. Hence it was patent from the first that some process was needed to rectify errors of this kind. Experiments were then made with oxy-hydrogen blowpipe, or the electric arc, to anneal such spots as were required to be drilled, and numerous mechanical devices for drilling, with drills of every design and method of tempering, were tried, until it seemed that the case was without a remedy.

* Abstract of Paper read before the American Institute of Electrical Engineers.

It was at this stage that the problem was referred to the Thomson Electric Welding Company of Lynn, and experiments were immediately undertaken to solve it. The process and apparatus necessary to carry it out, all resulting from the experiments undertaken, will be described presently.

The second method, which is used in England, has the advantage over the first, that there is no difficulty in carrying it out, provided there are no alterations made and no errors committed. The present method of construction seems to be to make beforehand a complete *model* of the vessel to be built; then make accurate drawings and full-size patterns of every plate, giving the exact location of every hole. These are then bored, tapped and countersunk to a depth of approximately $\frac{3}{8}$in. and of a much larger diameter, filled with clay, and then the plate as a whole is heated and hardened with water (*see* Fig. 1).

This method works apparently all right, although in spite of drawings and models, errors are made. There is no doubt, however, that it is a slow and very costly method of working, and would hardly ever be resorted to in the United States.

From the above it seems clear that there has existed a need for a process by means of which isolated spots, regardless of location, might be annealed so as to permit drilling and tapping.

If, by sending a current of large volume through any spot thus to be treated, the spot is brought to a temperature of approximately 1,000°F., there can be no doubt that the temper has been withdrawn. Experiments carried to that effect at once showed, however, that upon taking off the heating current the heat was so rapidly conducted away by the surrounding metal masses as to cause the heated spot to become chilled just as effectually as if it had been plunged into cold water. No method of outside protection of the heated spot would prevent this, and the *gradual* cooling of the spot had to be attained by different means—namely, a gradual and slow withdrawal of the heating current. The method of introducing the annealing current is best shown Fig. 2.

Two copper contacts, C C, are cooled by water circulating inside. The current enters the plate by one end, and leaves it by the other. Right under the contact the metal comes to a bright cherry heat (shown in black), while the portion intervening and partly surrounding the contacts acquires a temperature of just a visible red. Line H H indicate where the influence of the Harvey treatment stops.

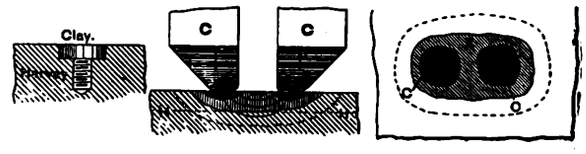

Fig. 1. Fig. 2. Fig. 3.

The shaded portions in Figs. 2 and 3 show the zone softened and ready to be machined, while the dotted line shows how far the heat radiation would cause the metal to turn blue. When cooled, the annealed portion shows a chocolate colour, while the place where the contacts have been resting is scaled and hard, and cannot be touched by a tool to a depth of about $\frac{1}{4}$in. These places can again be annealed later on, if required.

The apparatus necessary to carry out this process consists of the generator, the annealer proper (transformer) and the regulating apparatus.

The generator is commonly a separately excited alternator of variable potential, of a maximum of 300 volts and 100 amperes. The frequency, preferably, should be low, 50 cycles per second being used. When more than one annealer is to be run simultaneously from one generator, constant E.M.F. of the latter should be used, and each annealer regulated separately by a reactive coil. The annealer proper is a transformer similar to the well-known welding transformers. As the apparatus is to be operated outdoors, on board of vessels during construction, it is important that the same may be handled with immunity from electric shocks, even when operated in mist and rain.

To meet these conditions a copper-clad type of transformer is used, one in which the secondary is composed of two copper castings, each having a rectangular groove, which two halves, when bolted together, form a closed rectangular frame in which the primary is held enclosed. The hollow space intervening between primary and secondary is, moreover, filled with a heavy oil, which acts both as the insulator and conductor of heat from primary to secondary. The secondary, by completely surrounding the primary, affords an excellent mechanical protection, and prevents electric as well as magnetic leakage. The primary is a copper ribbon insulated with asbestos, and the ratio of conversion is 100 to 1. The transformer has two trunnions fastened to its sides, in a line a little above the centre of gravity, which trunnions swing in bearings, part of a yoke which straddles the whole. The yoke in its turn has a hook which may be secured to the latter at any place of the

Digitized by Google

arch, thus allowing the transformer to be suspended, like a compass in gimbals, in any position desired.

It goes without saying that the copper castings which compose the secondary are cut through at one place in the circuit. On either side of the cut two short platforms form the base for copper contacts of various shapes and sizes, by means of which the currents are made to enter and leave the plate to be annealed. These copper contacts are of forged copper, hollowed out to receive water circulation for cooling purposes, and terminate in narrow tips rounded at the end.

The weight of the whole annealer, being approximately 1,000lb., is sufficient to give proper contact pressure for all work on a horizontal plate. When inclined surfaces, vertical or otherwise, are to be worked upon, the transformer is suspended so that its weight shall not interfere with the contact pressure, which is obtained for work by bracing the contacts directly with wooden wedges against any object near by. On the outside of a hull, it is proposed to use a pair of electro-magnets, which are made to hold themselves against the iron hull, and form a support for the annealer. Fig. 4 shows some of the various shapes of contacts that are used in various positions.

The remarkable thing is the great amount of current that is being carried by the copper contacts into the plate. The contact surface is seldom more than about ½in. square, and yet 10,000 amperes are made to flow through it continually. This is equivalent to 40,000 amperes per square inch, a density which is only possible on account of the thorough cooling by the water circulation.

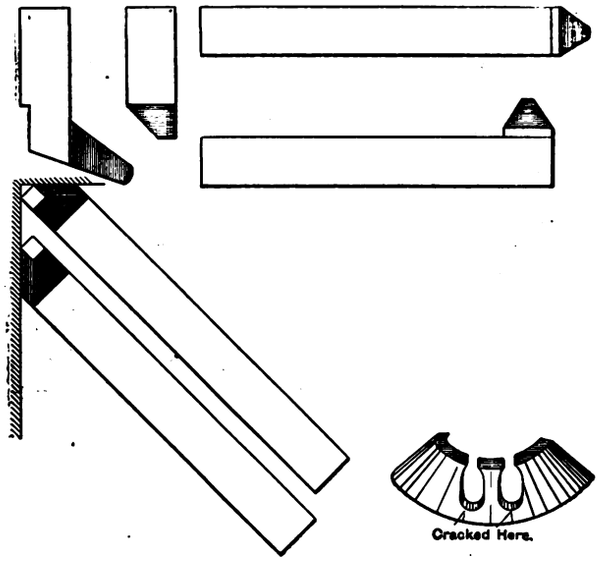

Fig. 4.

Fig. 5.

The regulating apparatus is in most cases simply a rheostat in series with the field of the generator. When more annealers than one are run simultaneously from one generator, as mentioned before, a reactive coil is interposed between the two, and this latter has been made automatic; that is to say, provided with a dash-pot, which permits the current to be reduced uniformly and at any given rate it is set for.

This reactive coil is composed of a solenoid coil of cable, well insulated, having a movable laminated iron core, which is raised out of the coil by means of a leather strap and winch. The core is composed of thin iron strips, placed side by side around a circle, and projecting radially from the same, and being held on top and bottom by a slate disc, in a manner similar to the securing of the copper segments of a commutator. No insulation of the core is necessary, and good ventilation is obtained. The core once raised out of the coil tends to return by gravity and the attraction of the solenoid, but is checked in its descent by a pair of dash-pots, one on each side of the coil. These latter communicate with each other, top and bottom, and have one of the pistons provided with a valve which opens when the core is raised, and closes when the core descends. The dash-pot cylinders are filled with a light mineral oil, which does not freeze nor clog under any ordinary conditions of temperature. An adjustable by-pass valve allows the oil to flow from the tube to the top side opposite. By opening or closing this valve more or less, any rate of descent and, consequently, diminution of current, can be uniformly obtained, without requiring any skill on the part of the operator.

The annealing operation is carried out as follows: The transformer is placed in position, the contacts touching the plate either side of the place marked to be annealed, and the primary current brought up by means of a rheostat to from 75 amperes to 90 amperes for about two minutes, according to the size of spot to be annealed, which will bring the metal to a dull red heat, a temperature at which a pine stick catches fire when held in contact with the plate. If no reactive coil is used, the current is now diminished by turning the rheostat one point every minute. If the reactive coil is used, the core is now raised by winch, the coil put in circuit by opening a short-circuiting switch, and then is allowed to descend on its own account. The operation generally takes *seven minutes*, all told. No difficulty has been experienced from the beginning. The annealing of individual spots was, however, only the stepping-stone to a more important work of a similar nature, work which was about to be given up, owing to what was considered insurmountable difficulties.

In the construction of a modern man-of-war, there are many armour plates which act as shields to the guns, and have to be perforated to allow the gun muzzle to pass through and to be either raised or lowered. Some of these shields are circular or oval, with narrow edges around the ports, in the case of Harveyed plate. To perforate these shields after carburation, and before being water-hardened, was the only possible way, since previous experiments had shown that prevention of carburation could not be relied on, and no process was known to anneal the plane locally after hardening. The hardening of a plate once perforated showed itself to be, however, almost impossible; in fact, a matter of chance. In most cases the plate cracked in two, as shown in Fig. 5, or the whole plate became distorted in such a way that it could not be used. As individual spots for holes could be annealed, there could be no doubt that a series of annealed spots could be likewise obtained by the electric process, following a line along which a cutting tool was expected to be run. The first attempt, therefore, and made in England, was to anneal a number of spots in proximity to each other in such a way that the annealed zones should overlap each other.

As described above, it is very important that the temperature of any individual part should be gradually and slowly withdrawn; and while for individual spots the only possible way was to do this by gradually diminishing the current, it was obvious that when a line was to be annealed, instead of annealing a number of spots side by side, the same effect of withdrawing the heat gradually

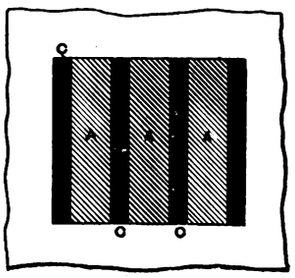

Fig. 6.

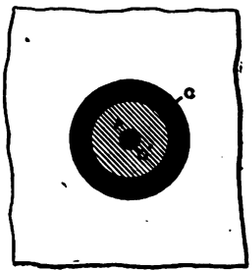

Fig. 7.

from one portion could be obtained by moving the apparatus itself relatively to the plate to be treated. The rate of this movement, of course, depended upon the rate at which the temperature should be allowed to fall in any particular spot to prevent chilling. The apparatus was therefore arranged to be moved along a line to be annealed, the motion being obtained by an ordinary screw and nut held in a bracket, the nut being turned at a predetermined rate controlled by a watch. It was found that a speed of about ¼in. per minute was sufficiently slow to ensure thorough annealing.

The copper contacts were of the simplest kind, as described above, bedding themselves partially in the surface, and when being dragged along by the screw and nut, raised in front of themselves a burr or chip similar to a planing tool. After a whole day's continuous use the copper contacts were found intact, while a number of chips from the steel surface were lying about. We thus had the peculiar phenomenon of a hard steel chip cut with a copper tool.

Upon the completion of the work, it was found that a strip about 2¼in. wide throughout the length over which the machine had been moved, could be operated upon by drills or a shaper, in a manner as easily as if it had never been hardened before.

In the work just described the apparatus was moved about, but in regular practice it would be better to construct a machine consisting of a large bed, on which the plate to be treated may be fastened and moved in any direction automatically at a predetermined speed, while the annealer proper is suspended in a given position above the plate. The annealing operation occupies but a small percentage of the time required for the cutting.

It is unnecessary to state that when the apparatus is used for continuous annealing the primary current is kept at a nearly con-

Digitized by Google

stant value, the diminishing of heat at any individual spot being obtained solely by the moving of the apparatus from it.

As mentioned before, the places where the contacts are passing over the plate, being brought to a higher temperature than any other, remain hard. Experience has demonstrated, however, that they may be re-annealed later on by treating the spots in the same way as any other hard spot on the plate. By this means we are therefore able to anneal any shaped portions, not merely lines. This is best seen in Fig. 6, in which a series of strips are annealed side by side (shown in shaded lines A). The hard-faced surface is then removed on such places by a planer and drill; the machine is then run a second time over the annealed strips, resting it this time on the bottom of the groove and on the softer metal, thus annealing the ridges C left between the annealed strips, on which ridges the contacts were running previously. When all these strips are annealed they may be removed by machine tools without any further difficulty. In a similar manner a large round place may be annealed, as shown by Fig. 7. The transformer is set on the plate, one contact resting on C′, the other at any other place in circle C; the apparatus is then slowly revolved around contact C′ as a centre, until the second contact has completed the circle C. The shaded portion A represents now the annealed surface, which is removed by a cutting tool. The contacts are then made to rest on either side of the centre C′, and the latter is annealed and removed in its turn.

The apparatus may also be used for the reversal of the annealing process; that is to say, for creating isolated hard spots in soft tool steel by sending a current through the spot to be hardened until it reaches a bright cherry heat, and then suddenly removing the current or machine.

Various other applications will suggest themselves in the operation of this process, already adopted by the United States Government. It may be used in the construction of burglar-proof safes, for dies and punches, for projectiles and other articles of a similar nature.

THE "BOOSTER" SYSTEM IN ELECTRIC RAILWAY WORK AT CHESTER, PA.*

What is believed to be the first actual installation of the so-called "booster" system for electric railway work was, some months ago, put into practical and successful operation on the lines of the Chester Traction Company, in Chester, Pa., under the supervision of J. Lester Woodbridge, of the Woodbridge and Turner Engineering Company, the licence to use this system having been purchased by the Traction Company from the owners of the patent covering this system.

Two lines were thus equipped, one extending to Darby, eight miles from the power house, and the other to Media, about seven miles from the power house. It became evident from past experience, that in order to handle the heavy Sunday and holiday traffic on these two lines through the summer in a satisfactory manner, about $20,000 must be expended for additional feed wire, unless some other arrangement were made to maintain the voltage. The Company were about to instal an additional generator of 400-kilowatt capacity, leaving idle two Short generators of 100 and 150 kilowatt capacity respectively. It was these two generators that were adapted and connected up as boosters for the two lines above mentioned, and they were so arranged that either can be used as a booster, or, by simply throwing over a switch on the switchboard, in case of emergency, either can be instantly connected up as a generator in multiple with the other machines, the corresponding feeder being at the same time restored to its original connection with the 'bus bar. Thus the total capacity of the station has not been reduced by the appropriation of these machines, and although their design is not just what it would have been, had they been specially built for the purpose, they are found to do their work satisfactorily, special connections and rheostats having been introduced into the field windings to make their action automatic.

For the information of those who are not thoroughly posted on the subject, it might not be amiss to state that the "booster" system consists in the introduction into a feeder, and in series therewith, of an additional electromotive force to compensate for the loss of voltage on said feeder. Usually this is accomplished by a generator whose voltage is made to vary with and adapt itself automatically to the varying loss on the feeder by causing its fields to be excited wholly or partially by the varying current on the feeder.

The installation in Chester proves conclusively, it is said, the advantage of the "booster" system in railway work, its adaptability to electric lighting having been already demonstrated in a number of instances; and whatever may be said regarding its economy for *continuous* use, as a substitute for feed wire, the net efficiency of the above-mentioned installation, which is operated only at times when the traffic is excessive, must be conceded at once. The additional coal consumption for operating the booster a few hours a week becomes a matter of minor importance when compared with the interest on the investment saved.

The practical results achieved in Chester in maintaining the voltage on distant portions of the line are very satisfactory. An approximately constant pressure of 500 volts is secured at the Darby terminus, regardless of load, when the "booster" is in operation, the loads on this section varying from zero to 450 amperes; without the "booster" a single car, climbing the Darby Hill, has been known to bring the voltage down to 275. At this low voltage it required a current of nearly 170 amperes to operate the car, and speed was very slow. With the "booster" in operation three cars have been brought up the hill simultaneously and at good speed.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

TO-DAY (FRIDAY), November 22nd.

PHYSICAL SOCIETY.

5 p.m. Meeting at Burlington House. (1) "An Exhibition of Photographs of Spectra," by Dr. G. Johnstone Stoney. (2) "A Direct Reading Platinum Thermometer," by R. Appleyard. (3) "Historical Note on Resistance and its Change with Temperature," by R. Appleyard.

MONDAY, November 25th.

NORTHERN SOCIETY OF ELECTRICAL ENGINEERS.

8 p.m. Meeting at the Palatine Hotel, Hunt's Bank, Manchester. Paper to be read: "The Use of Dust Destructors as Steam Producers for Electricity Supply Stations," by E. Manville.

TUESDAY, November 26th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be further discussed: "The City and South London Railway: Subaqueous Tunnelling by Shield and Compressed Air," by James H. Greathead.

WEDNESDAY, November 27th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read: "Locomotive Carriages for Common Roads," by H. H. Cunynghame.

THURSDAY, November 28th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary Meeting. Papers to be read: (1) "The Electric Wiring Question," by F. Bathurst; (2) "Concentric Wiring," by Sam Mavor.

SATURDAY, November 30th.

THE ELECTRO-HARMONIC SOCIETY.

8 p.m. Concert (Ladies' Night) at the St. James's Hall Restaurant (Banquet Room), Regent-street, W.

*** Particulars of Meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

Electricity in an Austrian Paper Mill.—The Leijkam-Josefthal paper mill, which was destroyed last spring during an earthquake, has now been rebuilt, and extensive use has been made of electricity in the fitting up of the mill. The water power of a river some two miles distant has been employed, and a generating plant of 500 H.P. has been erected. This plant consists of two turbines of 250 H.P. each, driving on to a common countershaft, to the two ends of which two "drehstrom" generators of 250 H.P. each are coupled. These machines are of the Ganz type, and give an E.M.F. of 3,000 volts when running at 170 revolutions per minute. The current is taken to the mill by three overhead conductors, where it is transformed to 300 volts. The loss in the conductors is about 5½ per cent. At the mill a third generator of 250 H.P. of the same type has been provided, but working at only a potential of 300 volts. This machine will be used as a supplementary one. From a main switchboard the "drehstrom" is distributed to various motors which drive the mill shaftings and the special machinery. There are motors of a capacity ranging from 160 H.P. to 3 H.P. A continuous-current dynamo for lighting purposes is driven off the main shaft.

Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*"

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The Rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	YEAR.	HALF-YEAR.	QUARTER.
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.

(Post free, payable in advance.)

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

RADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to* 4 *p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. *Vol. II. is in preparation.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free, 8s.
VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. 93 original illustrations, handsomely bound; price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. SNELL. 10s. 6d.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free 8s.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

"THE ELECTRICIAN" PRIMERS. In Two Volumes. Price: Stout paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 8d., post free, 8½d. Abroad postage extra.

THE WORK OF HERTZ. By Dr. O. J. LODGE. Price 2s. 6d.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. [*In preparation.*

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. [*In preparation.*

STEEL-PLATE PORTRAITS.

Of Willoughby Smith (out of print); W. H. Preece, C.B., F.R.S. (President of the Institution of Electrical Engineers); Michael Faraday (1s. extra); Sir John Pender, G.C.M.G., M.P.; Sir William Thomson, F.R.S. (Lord Kelvin); C. H. B. Patey, C.B.; Dr. John Hopkinson, F.R.S.; Dr. Oliver J. Lodge, F.R.S.; Prof. William Crookes, F.R.S.; Prof. von Helmholtz; Prof. W. E. Ayrton; Lord Rayleigh, F.R.S.; Cyrus W. Field: Werner von Siemens; Sir James Anderson; Joseph Wilson Swan; Mr. Alexander Siemens; Dr. Heinrich Hertz; Mr. R. E. B. Crompton; and William Sturgeon have been issued as Supplements to "THE ELECTRICIAN."

Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price 4s. 6d., carriage paid (U.K.)

NOW READY.—Vol. XXXV. of "THE ELECTRICIAN," bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

The published price of Volumes previous to Vol. XXXV. is 12s. 6d., post free 13s. 6d. Many of these Volumes are very scarce.

THE BOARD OF TRADE CONFERENCE.

The Board of Trade Conference has come and gone—gone, we trust, for a quinquennium at least. Not that the meeting in the Westminster Town Hall has been anything but exceedingly pleasant and fruitful. We cannot, of course, expect even the doubly revised electric lighting Regulations to be as concise and as permanent as the decalogue; but in the course of the two-days Conference between law-makers and law-breakers considerable progress was made in the direction of greater brevity, and it would be distinctly advantageous to the electric lighting industry if at least equal progress were made in the matter of permanency. The air of late has been full of rules, regulations and round-table meetings, and a lengthened breathing space is highly desirable, even though the Board of Trade rules may as a consequence lag a little behind instead of leading, as heretofore, the march of improvement. Three distinct classes of objectors have revealed themselves. There is the objector who deems all Board of Trade regulations unnecessary, who argues that as it is to the interest of the supplier of electric energy to maintain the continuity and constancy of the supply and to secure the safety of the public, enlightened self-interest will lead him to do of his own free-will anything and everything that can be reasonably demanded. Then there are individuals who do not object to Board of Trade rules, but hold that they should be mere generalities and obvious truisms; details, they contend, are better left to those who know. Lastly, there are some who realise that, under our present dispensation, regulations—

Digitized by Google

detailed regulations—are bound to be made, and, therefore, the best thing the electrical engineer can do is to take full advantage of the broad-minded policy inaugurated by Sir COURTENAY BOYLE, and to work up the Departmental edicts into a practical shape. Naturally, this latter genus predominated at the Westminster Town Hall on Tuesday and Wednesday.

As it may be some little time before the new Regulations are issued in their final form, it may not be without use to briefly review the principal results of the gathering. The ball was opened by a prolonged attack on the Board of Trade definition of "low-pressure"; naturally enough, everyone wanted the limit raised. In the end Sir COURTENAY BOYLE promised to consider the feasibility of a higher limit both for continuous and for alternate currents, and to be advised by a small committee of experts. Regulation 4, which lays it down that "no high-pressure electric line shall be used for the transmission of more than 200,000 watts . . ." was the next one attacked. The Chairman intimated that he was disposed to accept a 300,000-watt limit, but was doubtful as to the safety of a 500,000-watt maximum. Around Regulation 9, dealing with the testing and insulation resistance of new mains, the battle raged at great length; and the outcome was that the Board of Trade agreed to forego any demand for a definite insulation, and to merely require that "every electric main shall be tested for insulation after having been placed in position, the testing pressure being at least 200 volts, . . ."; service wires under a certain length being altogether exempted. The sting was then taken out of a large number of rules by their being made prospective. Regulation 13 was debated for some time, and finally Sir COURTENAY BOYLE agreed that central-station dynamos should only be submitted before coming into use to a pressure 50 per cent. greater than their normal maximum, in lieu of 100 per cent., as originally laid down. After a long discussion, the Chairman agreed to consider the question whether the Board of Trade could not relax Rule 23, requiring every high-pressure aerial line to be suspended from a bearer wire by means of insulating ligaments. Regulation 27, which ordains that all electric conduits, pipes and casings shall be so constructed as "to prevent any *influx* of gas from the adjacent soil," gave rise to a very valuable debate, in which Mr. PREECE, Prof. KENNEDY, Mr. CROMPTON and Mr. FRANK BAILEY took an active part. Ultimately, Sir COURTENAY BOYLE intimated that he was willing to accept the clause drawn up by the Institution of Electrical Engineers, in which by the substitution of "accumulation" for "influx" everyone is made happy.

On resuming its sitting on Wednesday morning the Conference set to work with renewed energy to mould the handiwork of the Board of Trade officials according to its own ideas, and succeeded to an astonishing degree in so doing. Rule 32 was much mutilated; Rule 33 was struck out, and Rule 8 of the old Regulations substituted. Rule 35 was transformed almost beyond recognition. In its original shape it ran as follows: "All street boxes which contain any vacant space shall be so constructed as to prevent any influx of gas or water. . . ." As amended it will run: "In the construction of street boxes used as transforming chambers efficient means shall be taken to prevent any influx or accumulation of gas or water. . . ." New Regulations 37 and 38 were struck out and old Regulations 15 and 16 substituted. Much time was spent in an endeavour to radically amend Rule 41, dealing with the position and protection of the consumer's main fuse; the result was a clarification of the wording and the authorisation of sealed as well as of locked receptacles for the cut-outs. New Rule 43 gave place to old Rule 18, mainly at the instance of Mr. H. M. SAYERS, and transformers in small houses will not have to be protected with all the elaborate care bestowed on an American millionaire's mausoleum. Rules 44-46, relating to consumers' wiring, were the subject of what threatened at one time to be an endless and desultory discussion. It was edifying to observe the extreme eagerness of those who, up till then, had been engaged in the game of whittling down rules applying to themselves, to impose all manner of stringent Board of Trade Rules and Regulations upon wiring contractors, and the extreme reluctance of this rule-making Department to take over this particular job had also its amusing aspect. The net outcome of the war of words is that in future no wiring is to be *permanently* connected if it be found that the insulation resistance is less than k/n megohms, k being a constant to be settled by our good friends at the Board of Trade, n being the "number of points for taking off current." But for the interposition of Mr. A. BROMLEY HOLMES, of the Liverpool Electric Supply Company, who mentioned motors, k would have been 75, as suggested by the Institution of Electrical Engineers. This addition is intended as an antidote to the very low figure of 5,000 ohms to which the insulation has to fall before the supplier of electricity *must* cut off the delinquent householder. Rule 48, relating to arc lights, resulted in the minimum permissible height of 10ft. being strictly limited to street arcs used for public lighting. After this concession, and a few more of minor importance, the meeting terminated amidst a chorus of mutual congratulation.

It only remains to be said that Sir COURTENAY BOYLE, as is customary with him, presided over the Conference with tact and urbanity, and that Prof. KENNEDY, Prof. AYRTON, Mr. CROMPTON, Mr. HAMMOND, Mr. H. M. SAYERS, Mr. HOLMES, and Mr. GAY did yeoman service in rendering these Regulations reasonable and workable; they did not content themselves, as many did, with making barren objections, they made valuable and fruitful suggestions.

REVIEWS.

Electrical Measurements. A Laboratory Manual. By HENRY S CARHART and GEORGE W. PATTERSON. (Boston: Allyn and Bacon.)

For students and others possessing an elementary knowledge of physics and mathematics, and wishing to gain a clear insight into the principles and practice of modern electrical measurement, this manual should prove decidedly welcome. It is marked throughout by conciseness, lucidity, and method. The orderly progress of the text is not interrupted by those practical hints which lend such a specious air of practicality to so many books of the kind. The proper place for practical hints is the laboratory itself; the proper person to give them is the individual actually supervising the test. Laboratory manuals dealing with such elaborate work as electrical measurement has now become should be strictly confined to elucidating methods and principles. It may be objected to this doctrine, that it tends to preclude the home student from acquiring a practical grasp of modern electrical measurement; but the elaborate and expensive electrical apparatus considered necessary in these days renders modern electrical measurement beyond the reach of anyone outside a well-equipped laboratory. Another marked feature of this volume is its extreme modernity and the frequent apposite references to more specialised works. The typography and diagrams are of the best.

Scientific and Technical Papers of Werner von Siemens. Vol. II. Translated from the Second German Edition. (London: JOHN MURRAY.)

How easy it is to sum up the life's work, even of the busiest and longest-lived men, in a few lines; and in many cases even when the written records of a life of assiduous labour are

Digitized by Google

gathered together by admiring friends or by an appreciative society, how small the bulk and how difficult is it for those who are not fully acquainted with the intrinsic value of the work done to resist a feeling of disappointment that so many years of toil should not have resulted in a greater mental output. Quite other is the feeling aroused by the contemplation of the two bulky tomes containing the collected Papers and patents of Werner von Siemens; the difficulty here is to properly digest the fare set before us. The second volume is devoted to the practical and commercial side of Werner von Siemens' work, and it exhibits very clearly the tenacious way in which Siemens ever kept pace with the steady march of electrical progress. From 1847 to 1867 we read of nothing but matters telegraphic; cable insulation, keys, relays, "constant galvanic" batteries. On January 17, 1867, came that remarkable note to the Royal Academy of Sciences of Berlin "On the Conversion of Mechanical Energy into Electric Currents without the Use of Permanent Magnets," in which the dynamo-machine, as we know it now, was first revealed; an energetic indication of his claim to priority in this discovery being made by Siemens before the same Society 13 years afterwards. Thenceforth telegraph Papers and patents are mingled with others relating to dynamos. On January 21, 1878, came a long-disquisition "On Telephony," in which the history of the subject up to that date is summarised, with many vaticinations with regard to the future. Amongst other proposals there is one for overcoming static induction effects whenever single telephone conductors are made up into multiple-cored cables by wrapping the single-insulated conductors with a thin layer of tinfoil. From 1880 onwards telegraphy is abandoned entirely, and the remaining pages of the volume are occupied by communications dealing with electric railways and electric meters. The Appendix contains two Papers on the necessity for a patent law for the German Empire, in the second of which the veteran inventor makes a vigorous appeal to his countrymen to raise their standard of commercial morality, and two Papers relating to the founding of the now world-famous "Reichsanstalt."

The pages of this work form a splendid record of practical many-sided inventive effort.

Life and Labour of the People in London. Vol. VI. Population Classified by Trades (*continued*). Edited by CHARLES BOOTH. (London: Macmillan and Co.)

We freely admit that anything is better than a mass of ill-digested, ill-arranged, unreliable statistics; nevertheless, we must candidly confess to a sense of disappointment at the small space allotted in this volume to the Electrical Trade in London and to the meagre information therein contained, and this whilst ready to make allowances on account of the youth of the industry and the vagueness of its boundaries. Less than 20 pages are occupied by curves, tables and comments, and these are rendered valueless for all practical purposes owing to the fact that surgical, scientific and electrical instrument makers are mixed up with cable-manufacturing hands, wiremen, &c. This poverty is all the more striking by reason of the proximity of the admirable section dealing with the printing trade. Electrical employees in London are easily divisible into some such classification as this:—Telegraph and telephone wiremen, house wiremen (bell and electric light), central-station hands, employees in heavy electrical engineering shops, in cable factories, glow-lamp factories, electrical-fittings factories and instrument-making firms. Tables and statistics with regard to the wages, hours, numbers and social condition of these various types of "electricians" would meet a decided want. As it is, the data gleaned are few in numbers and dubious in character. According to Mr. Booth the Electrical Trade in London numbers 4,930, of whom 3,887 are males over 20. The Electrical Trades Union, founded in 1889, has in London a membership of only 285, though it possesses a total membership of 1,700. The Amalgamated Society of Telegraph and Telephone Workers, notwithstanding the length of its title, has a very short roll of 150 members. We cannot think that this section of Mr. Charles Booth's important compilation will prove of much use to electro-statisticians.

THE BEHAVIOUR OF TRANSFORMERS UNDER THE INFLUENCE OF ALTERNATING CURRENTS OF DIFFERENT WAVE FORMS.*

BY DR. G. ROESSLER.

The general definition of an alternating current as an electrical current the strength of which periodically varies gives us only a partial conception. For the exact definition of any known alternating current we require either a statement of the mathematical law which is followed by the periodic variations of the current or a graphical representation of the same. By Fourier's theorem the general formula which describes any periodic function consists of a number of sine functions, the knowledge of which determines any alternating current in which the variation departs from a simple sine law; hence it is usual in all alternating-current problems to assume a simple sine variation of the current. This procedure is only justifiable if, by experiment, and by theoretical considerations, it is ascertained that the departure of the current from sine variation does not greatly influence its practical properties. How far this influence extends is as yet an unanswered question.

In the practical application of alternating currents we have to do with lamps, transformers and motors. With regard to lamps, it is obvious that, with glow lamps, owing to their conditions of working, the luminous intensity is independent of the form of the current wave if the $\sqrt{\text{mean-square}}$ of the current is constant. In the case of arc lamps, the influence of the form of the current wave on the luminous intensity requires special investigation. I had the honour of bringing before last year's meeting† a series of measurements which endeavoured to solve this problem. Their result was that the candle-power of alternating arcs depends greatly on the form of the potential and current curves, and in such a manner that a greater luminous intensity results from a given current, the longer the current maintains its maximum value—*i.e.*, the flatter the wave is.

Concerning the influence of the time variation of the alternating current on the behaviour of transformers and motors, our knowledge is very limited. An inquiry which the *Electrical World* of New York made on the occasion of a scientific controversy with the London *Electrician* last summer, although resulting in agreement on some points, brought forth the most contradictory answers. While, in the former journal, the position was taken that it was advisable in the building of an alternator to endeavour to obtain a sine variation of the E.M.F., the second journal considered that desideratum valueless, and "possibly" detrimental.

In face of these differences of opinion upon so important a point in alternate current working, it seemed to me right that I should bring before you a series of investigations which I have made with a transformer belonging to the electro-technical laboratory of the Berlin Technical High School. The period of investigation extends over the last year and a-half. Since an empirical result is only of value when based on a theoretical foundation, the description of the investigations, and the tabulation of their results, is followed by a theoretical explanation, which extends the results of the measurements to a general theory of the transformer under the influence of currents of different wave forms.

Description of the Alternators and Transformer.

As the source of current for the excitation of the transformer, two alternators of the electro-technical laboratory were used alternately, which machines were specially suitable for this investigation, since one of them gave an extraordinarily pointed potential curve, whereas the curve of the second was nearly sinusoidal. The first (Fig. 1) is a four-pole 5·5 unit machine, by Ganz and Co., with rotating magnets; the second is an older small 480-watt machine, by Wechsler and Co, with four magnets on each side of a ring armature having four coils (Figs. 2A and 2B). A complete description of the electrical arrangements of the two machines is given in last year's Paper, on the illuminating power of alternating-current arc lamps. To ensure uniform conditions of working with both machines it was necessary to use an old 480-watt transformer, on account of the small output of the smaller of the laboratory machines. It is probable, though the absolute efficiency of this old and small transformer cannot be taken as representative of that of the transformers of the present day, its relative behaviour, with the two alternators, may be taken as typical of all transformers, with either closed or open magnetic circuit.

The following is a description of the transformer: The iron circuit consists of 78 E-shaped wrought-iron plates, of the dimensions given in Fig. 3, and about 0·5mm. thick. The plates lie

* "Das Verhalten von Transformatoren unter den Einflusse von Wechselströmen verschiedenen periodischen Verlaufs." A Paper read at the third annual meeting of the Verband Deutscher Electrotechniker, Munich, July 6, 1895.

† See *The Electrician*, Vol. XXXIII., pp. 523, 539, August 31st and September 7, 1894.

alternately in the positions ⊔⊔ and ⊓⊓, and are insulated with silk paper. They are held together by a wooden frame, whereby the magnetic circuit is confined entirely to the iron plates. The total weight of the plates is 8·168 kilogrammes. The specific

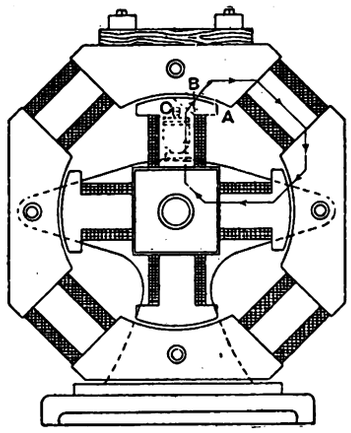

FIG. 1.—Ganz Machine.

gravity of the iron, obtained by weighing a sample in air and water, was 7·81 cubic cm., and the total volume 1,046 cubic cm. The two copper windings are arranged side by side, as in Fig. 4.

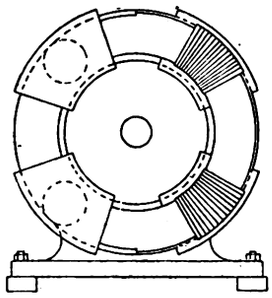

FIG. 2A.—Wechsler Machine.

The primary consists of 132 turns of 2·7mm. wire, the secondary of 265 turns of 1·8mm. wire. The primary resistance = 0·179 ohms cold, 0·214 ohms hot. The secondary resistance = 0·775 ohms cold,

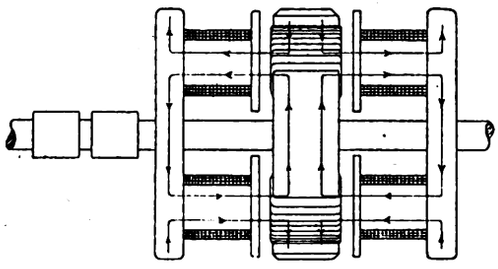

FIG. 2B.—Wechsler Machine.

0·943 ohms hot. The hot resistances were taken after four hours running of the transformer at full load. The working cross-section of iron, from the above data, was 20·19 sq. cm.

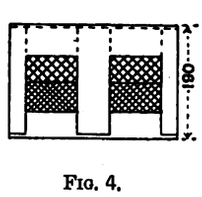

FIG. 4.

Measuring Instruments and their Calibration.

For the determination of the primary and secondary potentials a Cardew voltmeter was used. The primary current was measured by a Kelvin balance, and the secondary current by a Siemens-Halske electro-dynamometer (up to 5 amperes). The primary power was measured by a wattmeter made by the Helios Company, whilst the secondary load, being absorbed by glow lamps, was obtained by the product of the secondary current and potential.

In the calibration of these instruments for this investigation it was, for many reasons, desirable to ascertain whether the form of the waves affected the wattmeter readings. In the Cardew voltmeter and the current-measuring instruments there is, by the nature of their action, no dependence on the form of the wave. In the former, at each instant, the heating effect is proportional to the square of the potential; and in the others the force at any instant is proportional to the square of the current; the reading, therefore, for fixed coil position, always depends on the mean square. The instruments can also be easily provided with scales, upon which the $\sqrt{\text{mean-square}}$ is engraved. These $\sqrt{\text{mean-square}}$ readings are henceforth referred to in this Paper as R.M.S. (*Quadratische Mittelwerthe*). Each scale can then be obtained by standardising the instrument with known continuous currents, and can then be used for alternating currents of every kind. The wattmeter, in the form devised by Ganz, which is intended for the measurement of the mean value of the varying power, only gives this value correctly when the self-induction in the shunt circuit is negligible. If this is not the case the power, measured with alternating currents, will differ from that given by the scale for direct currents. The magnitude of the error is conditioned, by the self-induction of the wattmeter shunt, by the phase difference between the potential and current, which produce the required power, and by the form of the current curve. Prof. H. F. Weber, of Zurich, who first embodied the magnitude of these errors in a general formula, has found that in investigations on transformers by the Ganz wattmeter, the correction factor is less than $\frac{5}{10000}$, even when the current-curve differs greatly from the sine form, and the lag between current and potential is very great. The wattmeter of the Helios Company, used in these measurements, is almost identical with the Ganz instrument, so that Prof. Weber's calculations apply without alteration. Nevertheless, it was considered advisable to have experimental confirmation, on account of the capacity of the non-inductive shunt resistance, and other unknown factors. This was obtained in the following way:—

The alternating current was passed through a bank of glow lamps, and the potential measured by the two Cardew voltmeters, which had been calibrated for direct currents, and the current by the current balance. The latter was standardised against the standard of the Reichsanstalt, and had so small an error as to be negligible. The Siemens dynamometer was connected in series for calibration. The wattmeter was so connected that it measured the total power in the glow lamps and its own shunt. As the resistance is practically inductionless, the power is equal to the product of the potential and current given by the Cardew voltmeter and balance. The constant of the wattmeter is thus deducible. The results for the dynamometer and wattmeter are as follows:—

Table I.

Ganz machine.		Wechsler machine.	
Wattmeter.	Dynamometer.	Wattmeter.	Dynamometer.
c_1 = 0·001433	c_1 = 0·009080	c_1 = 0·001425	c_1 = 0·008997
0·001441	0·009054	0·001437	0·009000
0·001443	0·009080	0·001441	0·009002
0·001444	0·009055	0·001434	0·009018
0·001452	0·009023	0·001430	...
0·001447	0·009180	...	...
...	0·009C04	...	...
Mean c_1 = 0·001445	Mean c_1 = 0·00905	Mean c_1 = 0·001436	Mean c_1 = 0·009004
c_2 = 0·004530	c_2 = 0·02587	c_2 = 0·004482	0·02583
0·004528	0·02568	0·004514	0·02595
0·004525	0·02594	0·004521	0·02588
0·004555	0·02600	0·C04522	0 02600
0·C04541	0·02597	...	0·02592
Mean c_2 = 0·004536	Mean c_2 = 0·02590	Mean c_2 = 0·004510	Mean c_2 = 0·025?2

The suffixes 1 and 2 are for two connections of the fixed windings of the dynamometer and wattmeter. Each of these has a thick and thin coil. In the first readings the thick and thin coils were connected in series; in the second, only the thick coil was used. The difference observed between the constants are small: 0·62 and 0·57 per cent. for the wattmeter and 0·51 and 0·077 per cent. for the dynamometer. The fact that variations occur in the dynamometer shows that the wattmeter variations cannot be accounted for by the self-induction of the shunt. This conclusion is supported by a reading of the wattmeter, with continuous current, which gave c_2 = 0·004566, a greater value than the alternating measurements gave; whilst, on the other hand, the latter should have given the greater value, if the self-induction of the shunt was considered. The explanation of the small differences observed partly lies in unavoidable errors of reading, and partly in small irregularities of running of the machines, in consequence of which the individual values of the constant have a maximum difference of 1 per cent.

Digitized by Google

among themselves. So far as a difference of the constant exists, it has its explanation, not in the self-induction of the shunt, but in other causes, such as the capacity of the fixed coils of the current-measuring instruments and the wattmeter. By using the above empirically determined constants, in which these causes are allowed for, we may expect to get the true result.

The Measurements.

The two sets of measurements on the transformer were taken one after the other on the same day. The investigation with the Ganz machine was conducted in the morning, that with the Wechsler machine in the afternoon. The arrangement (Fig. 5) was such that, after the first set of measurements, only one main lead had to be altered, the remaining connections being unchanged. In order to reproduce the speed exactly in the two four-pole machines, the same

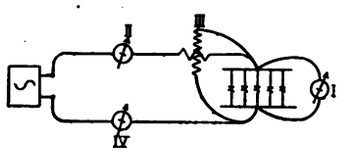

FIG. 5.—I. Cardew Voltmeter. II. Current Balance. III. Wattmeter. IV. Dynamometer.

tachometer was used in both investigations, its connecting link being attached to either machine. The Ganz machine was driven by an 8 H.P. Deutzer gas engine, which at the same time drove an "A.E.G." shunt machine which charged cells, and thus kept the gas engine well loaded. The speed was thus very constant, and by altering the excitation, or lead, of the "A.E.G." machine could be very finely regulated. The small Wechsler machine was upon the same transmission, being driven by the "A.E.G." machine as motor from the cells. The regulation gave a constant primary potential of 60 volts, and a tachometer reading of 1,250 revolutions per minute. The latter was checked by a revolution counter of Schaffer and Budenberg, connected with clockwork. The mean of six observa-

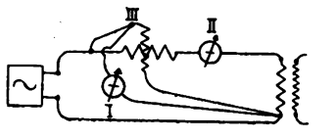

FIG. 6A.—I. Cardew Voltmeter. II. Current Balance. III. Wattmeter.

tions gave a value of 1,217 revolutions per minute; this gives, with a four-pole machine, a periodicity of about 41. The departure from this value during all the transformer measurements was always under 1 per cent.

In the connection of the wattmeter, it is necessary to remember that the instrument not only measures the power supplied to the transformer, but, if connected as in Fig. 6A, the wattmeter shunt has a higher potential difference than that of the primary circuit of the transformer; and, if connected as in Fig. 6B, a larger current flows through the fixed winding than that through the primary of the transformer. In the first case, a correction must be made for the potential difference between the shunt terminal and the trans-

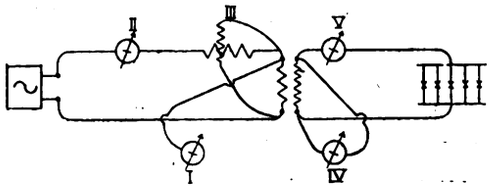

FIG. 6B.—I. Cardew Voltmeter. II. Current Balance. III. Wattmeter. IV. Cardew Voltmeter. V. Dynamometer.

former. If one of these potential differences is neglected, the other cannot be determined with sufficient accuracy, the difference depending, not only on the resistance, but also on the self-induction of the current balance and fixed wattmeter coil. These E.M.F.'s of self-induction cannot be determined very accurately by calculation, since their value depends also on the form of the current curve, and exact knowledge of the power in the transformer is impossible. If the wattmeter, balance and Cardew voltmeter are connected as in Fig. 6B, the power and primary current of the transformer is known from the readings of these instruments, and is independent of the forms of the potential and current curves.

Let t be the time, J the current as measured by the ampere balance, i the total shunt current, J_1 the primary current of the transformer, and $E p_1$ the primary potential; then, at each instant, $J_1 = J - i$.

If the inductionless resistance of the Cardew voltmeter, and wattmeter shunt, in parallel, be w, $i = \frac{E p_1}{w}$,

$$\therefore J_1 = J - \frac{E p_1}{w},$$

and
$$\frac{1}{T}\int_0^T E p_1 J_1 \, dt = \frac{1}{T}\int_0^T E p_1 J \, dt - \frac{1}{T}\int_0^T \frac{E p_1^2}{w} dt \quad . \quad . \quad (1).$$

Inserting for T in this equation the periodic time we have

$\frac{1}{T}\int_0^T E p_1 J_1 \, dt$ is the primary power of the transformer;

$\frac{1}{T}\int_0^T E p_1 J \, dt$ the power measured by the wattmeter;

$\frac{1}{T}\int_0^T \frac{E p_1^2}{w} dt$ the power lost in the shunt.

The latter is known from w, and the square of the potential difference measured by the Cardew voltmeter, which is $\frac{1}{T}\int_0^T E p_1^2 dt$.

The general equation (1), for all alternating currents, thus enables us to determine the mean power supplied to the transformer by the measured quantities. For the calculation of the primary current we have the equation

$$J_1^2 = J^2 - 2 J i + i^2$$
$$= J^2 - 2\frac{J E p_1}{w} + \left(\frac{E p_1}{w}\right)^2.$$

Hence,

$$\frac{1}{T}\int_0^T J_1^2 \, dt = \frac{1}{T}\int_0^T J^2 dt - \frac{2}{w}\frac{1}{T}\int_0^T E p_1 J \, dt + \frac{1}{w^2}\frac{1}{T}\int_0^T E p_1^2 dt.$$

In this equation

$\frac{1}{T}\int_0^T J_1^2 \, dt$ is the effective or R.M.S. of the primary current;

$\frac{1}{T}\int_0^T J^2 \, dt$ the current measured by the balance;

$\frac{1}{T}\int_0^T E p_1 J \, dt$ the power measured by the wattmeter;

$\frac{1}{T}\int_0^T E p_1^2 \, dt$ the square of the potential measured by the voltmeter.

If we denote henceforth by J, J_1 and $E p_1$ the R.M.S. of the current strength and potential difference, and by A_1 the power measured by the wattmeter, then the primary current J_1, and the primary power A_1, are given by the equations

$$A_1 = A - \frac{E p_1^2}{w}$$

$$J_1^2 = J^2 + \frac{E p_1^2}{w^2} - 2\frac{A}{w}.$$

It is to be observed that the latter equation, with the broadest interpretation, would give the primary current simply as the difference of the measured current J and the shunt current $\frac{E p_1}{w}$, if the transformer had no self-induction, then $A = E p_1 J_1$ and

$$J_1^2 = J^2 + \frac{E p_1^2}{w^2} - 2\frac{E p_1 J_1}{w} = \left(J - \frac{E p_1}{w}\right)^2.$$

This method can, with small transformers, and especially with those having open magnetic circuits, give rise to great errors.

On open circuit, in the present investigation, we have, for example, $J = 1{\cdot}598$, $A = 51{\cdot}27$, $E p = 60\ 54$, and $w = 227$.

If we calculate J_1 by the formula

$$J_1 = J - \frac{E p_1}{w},$$

we have $J_1 = 1{\cdot}598 - 0{\cdot}266 = 1{\cdot}332$ amperes.

In reality, however, $J_1^2 = J^2 + \frac{E p_1^2}{w^2} - 2\frac{A}{w}$

$$= 2{\cdot}552 + 0{\cdot}07076 - 0{\cdot}4512 \quad \therefore \quad M J_1 = 1{\cdot}474 \text{ amperes.}$$

The difference between the results amounts to about 9·6 per cent. The value obtained from the first method is always too small.

In the secondary circuit, as in the former case, the loading was effected by glow lamps; the calculation of the current J_2 from the reading J of the dynamometer, and the reading $E p_2$ on the Cardew voltmeter, is given by the simple equation $J_2 = J + \frac{E p_2}{w}$. The resistance of the shunt, which in the secondary circuit is simply the Cardew voltmeter, is in the present case 390 w.

(To be continued.)

THE BOARD OF TRADE REVISED ELECTRIC LIGHTING REGULATIONS.

CONFERENCE AT THE WESTMINSTER TOWN HALL.

A Conference of Corporations and companies concerned in the Regulations made by the Board of Trade under the Electric Lighting Acts was opened on Tuesday in the Town Hall, Westminster. Sir Courtenay Boyle, K.C.B., of the Board of Trade, who was accompanied by Mr. Hopwood, C.B., C.M.G., Sir T. Blomefield, Bart., of the Board of Trade, Mr. W. H. Preece, C.B., chief electrician to the Post Office, and Major Cardew, R.E., presided.

In opening the proceedings, Sir COURTENAY BOYLE stated that the Board, finding it necessary to revise the Regulations made by them under the provisions of the Acts of 1882 and 1888, had thought it convenient as well as courteous to give to all who had raised objections an opportunity of stating those objections verbally, thereby assuring that the Board of Trade's final decision might not be come to until after carefully hearing all that could be said on the various matters dealt with in the Regulations. Although the entire responsibility rested on the Board of Trade, who could not divest themselves of that statutory responsibility, he could assure those present that the Board would carefully weigh all the arguments and representations that might be placed before them.

The TOWN CLERK of MANCHESTER observed that it was felt by all municipal bodies which, like that of Manchester, had spent large sums on works that might be affected by the result of this Conference, that it would be of great importance that they should have an opportunity of seeing and making observations on any altered Regulations that might be decided upon before they were finally enforced.

Sir C. BOYLE promised to consider the point, though he hoped the Board would be able to arrive at a final conclusion as a result of the Conference.

The Conference then proceeded to consider the proposed revised Regulations in detail, and the criticisms submitted by undertakers and public bodies. The first controversy arose on the proposed new definition of "low pressure."

Sir C. BOYLE said they had better come to the question of whether the proposed maximum of 300 volts should be raised.

Mr. HAMMOND remarked that it was known to everyone in the room that great improvements had been made in the distribution of electricity, and that reliable electric lamps had been introduced working at from 200 to 250 volts. It was most desirable that this improvement should be facilitated. They hoped that in time they would be allowed to go up to 600 volts. He maintained that that would be a perfectly fair limit from the point of view of safety, but if it was thought too great they ought to have at least 500 volts. The Board of Trade had already sanctioned that limit for traction purposes, and the danger was less in matters of lighting. He had himself had shocks at 600 volts several times, and such shocks did not injure a man in ordinary health.

Dr. JOHN HOPKINSON pointed out that the case of Manchester required consideration, for in that town 400 volts pressure was occasionally required. The Manchester Corporation had laid out £175,000 up to the end of last March, and since then, for purposes of extension, they had obtained sanction for the expenditure of a further £100,000. This had been done on the undoubted feeling of security that the work would be allowed to go on as the system was originally laid out unless serious damage were found to result from it or serious risk. What were the facts? In Manchester they had no trouble whatever with their electric mains—they had set no buildings on fire, they had hurt no one, and they had given thorough and complete satisfaction to a large number of consumers. If there had been danger from shock surely they would have found it out, seeing that they had 937 consumers wired, with many more coming on. A large number of these had been on for a considerable time, and no one had ever complained of having received a shock that had caused inconvenience. Of course, as many of them knew, a shock could be got, and a smart one, at 400 volts.

Sir C. BOYLE said he did not wish to press the point home, but it was clear that Manchester had been infringing the Regulations.

Dr. HOPKINSON said it was a pity to waste time in considering that matter. He would deal with it if it were desired, but he did not wish to waste the time of the meeting. There was the fact, however, that in Manchester they had been working with a pressure of something like 420 volts; the thing had worked well, and, financially, had been a great success. He believed there was no town in the kingdom which had a better record than Manchester, and which had made a larger percentage and profit. They had proved that they could give the public the benefit of the electric light economically, and they desired that they should be allowed to work at the pressure they had been working at. It would be exceedingly hard on Manchester if they were to be interfered with in doing what they had done in the past, and done with marked success.

Sir C. BOYLE: If you are going to develop that argument I shall have to enter upon the question of whether you have or have not been infringing the Regulations.

Dr. HOPKINSON said this was not a question to be dealt with here. The Board of Trade would have its remedy if the Manchester Corporation had been doing wrong. They would be perfectly prepared to deal with the matter if it were raised elsewhere. It would be hard if the Regulations were to be so altered as to press more heavily on Manchester than they did at present; and, further, if they were so altered with regard to future works which had to be worked from the same centre of supply as that now used. The experience of Manchester fully justified the Board of Trade in sanctioning pressure up to 500 volts.

Mr. Alderman HIGGINBOTTOM, referring to the Manchester case, said he could not agree that they had gone beyond the Board of Trade Regulations. They had a low-pressure system of 400 volts sanctioned by the Board of Trade on two occasions—once when the Order was granted, in 1890, and again, in a letter from Sir C. Boyle himself, in 1892, in which it was said that the Board of Trade approved of the system of which the description was annexed—and that description was given as a low-pressure direct-supply continuous-current system at constant pressure of 400 volts. By leaving out the letter "a" and the words in the original Order they would convert the Manchester system from a low-pressure into a high-tension system, and the consequence would be that they would have to re-lay the whole of their mains, of which they had more than 89 miles laid up to the present time. That was a very serious thing to them, and if it was contemplated to make the new regulation retrospective, as was rather suggested, it became a matter of enormous importance. Only last March the whole of their plant capacity was taken up, and they had to go to the Local Government Board for borrowing powers. The Local Government Board granted them £100,000, and a large part of that had been spent. It would be all gone before next June. Their contention was that this new regulation should not be made to include the case of Manchester, which was a special system, namely, a five-wire system, and one which had proved so successful in every way that they had not been called to account by the Board of Trade or by their consumers. He thought in the new Regulations the Board of Trade ought to keep to the voltage that had been sanctioned by the Board of Trade and the Local Government Board. To make the Regulations retrospective would be a serious thing to the Manchester Corporation, and would mean a great increase in cost to the consumer, who now could purchase the electric light at a price that no other municipal body had hitherto produced it at. The Manchester Corporation asked that the regulation should be amended in accordance with the observations they had made on the agenda.

Prof. AYRTON thought a certain amount of difficulty had arisen from its not being made clear whether the pressure referred to any two wires leaving the central station, or to two wires going into a particular house. It seemed to him that there would be a great danger in the number of volts specified depending on what interpretation was to be given to the Order. The regulation said: "The expression 'pressure' means the difference of electrical potential between any two conductors through which a supply of energy is given." Did it mean any two conductors which left the central station, wherever those conductors might go to, or did it mean any two conductors in a house?

Major CARDEW said the question as to what was to be considered high pressure depended upon many other considerations besides the possibility of danger to human life. He did not say that in selecting 300 volts, continuous, they had not arrived at a limit which very fairly did discriminate between the pressure which might under certain conditions be dangerous to life and the pressure which could be taken by anybody with impunity. The Regulations provided that low-pressure conductors need not be continuously insulated in the streets, and that was one very material point to bear in mind in considering what should be the limit. They knew that whatever dangers arose—such as damage to pipes, explosions, fires—would be increased by an increase of pressure. Supplies such as that of Manchester were not free from danger. Though nothing might have happened at Manchester itself, taking those supplies generally, there had been regrettable accidents in connection with them. For instance, there was the accident to the St. Pancras mains, which must be fresh in the mind of everyone. Then there was a similar system at Southampton, where they had lately had an explosion caused by the same means which it was found had been at work at St. Pancras. There had been explosions on the St. James's and Pall Mall system and under the Preston Electric Lighting Company and elsewhere, but it would be invidious to hold up particular companies to reprobation. With these systems of bare conducting mains there had been accidents, and he held that if they increased the pressure at which they allowed these uninsulated, uncovered mains to be laid, they must to some extent increase the risk. Mr. Crompton had pointed to the fact that in some instances, for traction purposes, thay had allowed the use of 500 volts, and he had stated it as his opinion that what was allowed for traction might be quite equally well allowed into houses. He (Major Cardew) must differ from that. Five hundred volts had only been allowed in the case of overhead wires under very severe restrictions. Those wires were necessarily put up in a permanent and strong way, and were not likely to become into contact with by anyone; but, on the other hand, when they had wires going into houses and open to people without any electrical knowledge at all touching them, they must provide that those wires should be perfectly safe. They were put into children's nurseries, and no one knew what might happen there. Apart from any injury and alarm caused by electric shock, there was the fire risk in houses as well. They had had a strong opinion on the matter from Mr. Musgrave Heaphy. Other speakers had pointed to the great advantage to be derived from the use of 200-volt lamps. All the speakers had been dealing with the question from the point of view of supply. They had had no one come forward on behalf of the consumers to say that they had no fear of it, and he did not think they would find an educated consumer who knew much about electricity who would say there would be much advantage in the use of such lamps from his point of view. All the advantages to be derived from the use of high-pressure lamps were on one side, though it must not be forgotten that the use of them cheapened the supply, and that therefore to that extent they were of benefit to the consumer. To suddenly double the pressure there must be some risk of fire—risk of the arcing of switches and of increased leakage at the fittings. He did not think it would be right to suddenly raise the pressure throughout a whole district in that way. Something would be wanted to guarantee that the pressure in houses should not exceed 300 volts' limit. Taking the question of danger to life, the only instance, he was happy to say, which bore materially on the point in the United Kingdom had been the lamentable accident at Port

Digitized by Google

rush. There, they knew, the pressure could not have exceeded more than 300 volts by anything more than a slight fraction—possibly it might have been 320. There they had an unfortunate man thrown upon a charged rail making a good contact. Probably because the shock deprived him of the power of moving, he remained in contact longer than anyone would willingly remain in contact with such a current. The doctors who saw him thought that if the electric shock had not been added to the mechanical shock he would not have been killed. Besides this case they had had evidence of the death of horses and cattle on the line. It could not be said that with 300 volts the shock could be taken with absolute impunity under all conditions. It was impossible to draw an exact line, and to say "At this point there is danger—below it there is none." If they hastily raised the limit, which had worked well hitherto, in a short time they would be again pressed to raise it. He thought the proposal to slightly raise the limit laid down for low pressure, as regarded alternating current, so as to give them 200 volts, was worth considering; but as regarded continuous current he need hardly point out that under the existing Regulations 200-volt or 250-volt lamps could be used with the consent of the consumer. The regulation would prevent the use of such lamps except with the assent of the consumer, and that, under present conditions, was desirable. If any consumer liked to be supplied with 250 volts pressure he could get it now under the continuous-current system.

Sir C. BOYLE said he had no hesitation in stating that he intended to advise the Board of Trade to raise the 150 volts in the case of alternating pressure to a higher figure—to 220 volts or some other figure.

Mr. SIEMENS said with regard to the St. Pancras accident that if they had had only 50 or even 30 volts between the mains the same thing would have happened. The Portrush case could not be compared to the London case, where the bare wires were out of the reach of everyone but workmen. What was dangerous and what was not really depended upon the individual.

Sir C. BOYLE said he thought they had discussed this regulation long enough. He could not to-day announce what advice he should give the Board of Trade, but he honestly said that the suggestions made would be carefully borne in mind. His personal opinion was that the figure 300 in the case of continuous pressure might be slightly raised. Also, it would be his duty to advise the Board of Trade that, after all, when they were deciding what should be high pressure and low pressure, they were only deciding that in cases of high pressure certain additional precautions should be taken. There was no prohibition of the high-pressure system, but only insistance on additional precautions in connection with it.

On *Regulation* 2, Sir C. BOYLE, in reply to the representative of the Southport Corporation, said that a consumer who for experimental purposes converted low pressure into high pressure would do it at his own risk.

Regulation 4 was as follows: "No high-pressure electric line shall be used for the transmission of more than 200,000 watts, or in the case of an aerial line 50,000 watts, except with the consent in writing of the Board of Trade; and efficient means shall be provided to prevent this limit being at any time exceeded."

To this exception was taken on the ground that 200,000 watts was too low. The Institution of Electrical Engineers suggested that the figure should be 500,000.

Sir C. BOYLE said he was disposed to accept the alteration from 200,000 to a higher figure.

Mr. CROMPTON said that by means of an automatic cut-off it was as easy to deal with 500,000 watts as 200,000. The matter should be allowed to be worked out on commercial lines, as it did not affect the public. It would be unwise to unduly fetter engineering designs, and that he was sure Sir C. Boyle would be the last to wish to do.

Major CARDEW said that in the case of a breakdown, which was the danger foreshadowed by the regulation, the energy might be converted into heat at the point where the cable had broken down. If that amount of heat were discharged at one point in the street, though it might be underground, something must happen. They were not going to generate all that heat and have nothing result from it. This was the way in which the Cannon-street and Sloane-square explosions occurred. The sudden generation of heat was enough to cause a serious explosion without an accumulation of gas.

Sir C. BOYLE said he should advise the Board of Trade to raise the 200,000 watts, but he should have to consider whether he could go so far as Mr. Crompton and propose the substitution of 500,000 watts. He thought that would be going too far. The consent of the Board of Trade in writing to an excess of the watts was always obtainable.

Regulation 5.—"Every high-pressure electric line, conductor, or other apparatus shall be protected by a suitable automatic quick-acting cut-off."

Dr. HOPKINSON said that under the old Regulations at Manchester they had been required to put in fuses, but they had never ventured to do so for the reason that they feared to run a greater risk of extinguishing the light than any other risk. In Manchester they had had no trouble from the absence of fuses. No doubt they had not followed the Board of Trade Regulations, and he submitted that it would be better to omit this regulation requiring all mains to be protected by fuses.

Sir C. BOYLE said the regulation only applied to high pressure.

Regulation 6.—"In every case where any transforming apparatus is used to convert a high-pressure supply into a low-pressure supply, some suitable automatic and quick-acting means shall be provided to protect the low-pressure system from any accidental contact with or leakage from the high-pressure system, either within or without the transforming apparatus."

Sir C. BOYLE, in reply to a question whether the automatic means here referred to were really needed when earth-shielded tranformers and earthed metallic shielding between high-tension and low-tension conductors were everywhere employed, said he should think they would be.

Regulation 7.—"The maximum working current in any conductor shall not be sufficient to raise the temperature of the conductor or any part thereof to such an extent as to materially alter the physical condition or specific resistance of the insulating covering, if any, or in any case to raise such temperature to a greater extent than 30° F.; and efficient automatic means shall be provided which will render it impossible for this maximum working current to exceed such limit to the extent of 50 per cent., even for short intervals of time; and special care shall be taken that the cross-sectional area and conductivity at joints are sufficient to avoid local heating, and that the joints are protected against corrosion."

Sir C. BOYLE said this was an old regulation. There had been no difficulty in working it up to the present.

Dr. HOPKINSON, on behalf of the Manchester Corporation, urged that the regulation should be omitted. In the large majority of low-tension stations it was not carried into effect. Cut-outs were not used, and those who were best qualified to speak on the subject said they were better without them. A law which was constantly transgressed, and transgressed with impunity, would be better revoked. He proposed to omit "and an efficient automatic means shall be provided which shall render it impossible for this maximum working current to exceed such limit to the extent of 50 per cent., even for short intervals of time."

Sir C. BOYLE said he was advised that he could omit those words; therefore he would do so.

Regulation 8 was agreed to.

Regulation 9.—"Every electric line shall be tested for insulation after having been placed in position, the testing pressure being at least 200 volts, and the undertakers shall duly record the results of the tests of each line or section of a line. No electric line shall be brought into use in which this test indicates an insulation resistance less than at the rate of 100,000 ohms per mile for every volt of pressure of the supply, unless it is connected with earth with the consent of the Board of Trade, in which case the insulation resistance of such electric line shall not be less than 10 megohms."

The Conference then proceeded to consider Clause 10 of the regulations dealing with the insulation test to be applied to every complete circuit used for the supply of energy, including all machinery, apparatus, and devices forming part of, or in connection with, such circuit. A large number of criticisms upon this rule had been sent in in writing. The representative of the Bournemouth and District Electric Supply Company submitted suggestions to the effect that on low-tension mains tests at much longer intervals than a week would be sufficient, and that to maintain the insulation at the standard mentioned might involve much interference with consumers' installations, over which undertakers had no effective power, especially if the low figure of 5,000 ohms was retained.—Sir C. Boyle and other speakers pointed out that under the existing regulations it was quite possible to maintain the insulation required, because in any case where private consumers were responsible for excessive leakage the undertakers could absolutely refuse to continue a supply to any customer whose wires were not in a proper condition. On the other hand, it was pointed out by Mr. Crompton that it would be unreasonable to require a weekly test. Major Cardew pointed out that the test could be carried out without in any way interfering with the supply of electricity. His idea was that close observation should always be kept as to faults of leakage.—Mr. Crompton pointed out that they could not ascertain whether a leakage was in their own circuit or in the house circuit without detaching the house service from their own, and private consumers had a great objection to officials of the supply companies having an almost indiscriminate right of entrance to their houses to make the examinations.—Prof. Kennedy said that the Westminster Company tested their leakage every morning, and they found no difficulty in doing it. When they found that there was a large leakage going they used their best efforts to ascertain where it was.

Mr. PREECE said that, as one who had had some considerable experience in the practical maintenance of the electrical systems, he would like to point out that there was no more important clause in these draft Regulations than that which was now under discussion. There was not a single electrical enterprise that he knew of that had not been maintained in efficient order by the practical carrying out of such regulations as that now proposed. It was impossible for consumers, or undertakers or the Board of Trade to ensure that the law was properly carried out unless some such regulation as this was introduced. It had been suggested by Gen. Webber that the wording of the clause was not wide enough, and that it did not include lamps and apparatus in houses. To his (Mr. Preece's) mind, however, it was quite clear that the words "complete circuit" included everything, and unless undertakers had a certain command over the part of the circuit in the consumer's house they could not have control over the whole of the system. All of them who had any practical experience knew that the chief source of trouble lay in the way in which cheap work in connection with installations was put into houses, and, subsequently, as far as maintenance was concerned, neglected. They had all had experience of having consumers' houses disconnected in order to call in firms to put the wires into proper order. It had been urged that once a week was too frequent a test. In regard to that he thought it right to say that there was not in the country a much larger system of electric application to be kept in order than that of the telegraphs and the post-office service of the Government. Their practice was every morning without exception to test every circuit. They found no difficulty in doing that. It was done with the greatest ease, and by that means they obtained the earliest information of faults and secured the proper maintenance of the service. He could not conceive any well-conducted electric lighting company in this country having any difficulty in carrying out a proper test once a week. Therefore, as a practical man, he urged the Board of Trade very strongly to maintain the draft clause in its present form. The test was not a very serious one, and in exceptional cases the Board of Trade might make an exception to the rule.

Digitized by Google

Major CARDEW said he thought they must look to the supply companies to maintain the supply throughout, and it was quite in the power of the companies to cut off the supply where they found excessive leakage after addressing a remonstrance to the consumers.

Sir C. BOYLE: It is not necessary for me to announce any decision to-day. The observations that have been made will be carefully reported to the Board of Trade, and their decision will be announced in the usual way.

Clauses 11 and 12, relating to the quality, amount and thickness of the insulation of leads and apparatus, were discussed together.

Sir C. BOYLE, referring to Clause 12, said he was prepared to advise the Board of Trade that it should be made prospective, but only on condition that if any evil effects were discovered from the absence of the regulation in existing cases the company must expect to have the regulation made applicable to it retrospectively.

On Clause 13, which provided that "no electric line, machine, device, or apparatus intended to form part of, or be connected with, a high-pressure circuit shall be brought into use unless the insulation thereof has withstood the continuous application during one hour of twice the pressure to which it is intended to be subjected in use, and that the undertakers shall duly record the results of such test,"

Prof. KENNEDY thought that the word machine should be left out of the regulation.

Sir C. BOYLE: But you want some test even of an alternator.

Prof. KENNEDY: Yes; I would suggest 25 per cent. above its nominal pressure.

Mr. HAMMOND: I would suggest 50 per cent. I think the apparatus should bear in the public interest, the highest tests.

Mr. CROMPTON doubted whether any test of these apparatus on their own premises did much to secure the safety of the public. It rather savoured of grandmotherly legislation.

Sir C. BOYLE: I can only say that there is constant pressure being put upon the Board of Trade to be a great deal more grandmotherly than they are at present.

After further discussion,

Sir C. BOYLE said the probability was that the decision of the Board of Trade would be to make the test twice the normal pressure in the case of an electric line and 50 per cent. in the case of a machine, device, or apparatus.

On Clause 15, which provided that "where any accident by fire or explosion, or any accident causing or likely to have caused personal injury, occurs at any part of any electric line or work to which these Regulations apply, the undertakers shall give immediate notice thereof to the Board of Trade," the Town Clerk of Manchester asked that it should be so altered as not to apply to trivial accidents, but only to those of a really serious character.

Sir C. BOYLE: How do you define a serious accident?

Eventually it was agreed, subject to the final decision of the Board of Trade, to alter the draft regulation so that it should read as follows: "Where any accident causing, or likely to cause, personal injury occurs at any part of any electric line or work, the undertakers shall give immediate notice thereof to the Board of Trade."

Regulations 16, 17, 18 and 19, dealing with aerial lines, were agreed to in substance as proposed.

Clause 23 enacted: "Every high-pressure aerial line shall be efficiently suspended by means of insulating ligaments to suspending wires, so that the weight of the line does not produce any sensible stress in the direction of its length. All suspending wires, if of iron or steel, shall be galvanised."

Mr. CROMPTON urged that when aerial cables were used at all, except in neighbourhoods where the population was sparse, it was best to make them of copper and self-suspending.

Major CARDEW: What distances between the poles?

Mr. CROMPTON: From 50 to 100 yards.

Sir C. BOYLE: What happens in that case if the cable breaks?

Mr. CROMPTON: It falls down just as at present.

Sir C. BOYLE: And anyone beneath it would be in a bad way?

Mr. CROMPTON: Yes, but these cables have fallen down, and the tags, which are the most vulnerable part of the construction, have never prevented such accidents. It is always the suspending wire that breaks.

After further discussion, Sir C. BOYLE said that Mr. Crompton's argument on the matter would be carefully considered.

Several minor points having been discussed, the Conference next proceeded to discuss the Regulation (No. 37) that "all conduits, pipes, or casings used as receptacles for electric lines shall be constructed of durable material, and of ample strength to prevent damage from heavy traffic, and, where they are laid in streets in which gas mains are also laid, shall be so constructed as to prevent any influx of gas from the adjacent soil."

Mr. HAMMOND and others urged that the rule was unfair to those engaged in the supply of electric lighting.

Mr. PREECE said that from 44 years' experience of fighting between gas and the pipes they had succeeded in the Post Office at least in getting what they wanted. In London alone there were 8,000 boxes, and in the United Kingdom 16,000 boxes in connection with the Post Office, and it was a very rare thing for the year to pass without several explosions taking place. He would like very much to point out, in reference to what Mr. Hammond had said, when he advocated leaving the bottom of the boxes open, that that was what the Post Office did not do, and were prevented from doing. They were obliged to fill them up to prevent the influx of gas. They had done everything that reasonable beings could do to prevent the influx of gas into the boxes, but it did get in nevertheless, and through people throwing down matches or through sparks arising from other sources there would, when there was an accumulation of gas, be an explosion. It was difficult to prevent it. He supported the suggestion put forward by Mr. Crompton on behalf of the Institution of Electrical Engineers, in which the word "accumulation" was substituted for "influx."

Sir C. BOYLE said the desire of the Board of Trade officials was to compel the electric lighting companies to keep the gas out of their boxes, and to compel the gas companies to keep their gas from getting into the electric companies' boxes. He knew, however, that it was difficult, if not absolutely impossible, to enforce that obligation in either case. Therefore, the clause as it stood on the paper must fall to the ground. He would propose a clause to the Board of Trade based on the recommendation brought by Mr. Crompton and supported by Mr. Preece.

Mr. CROMPTON expressed his gratitude for the concession made by Sir C. Boyle.

WEDNESDAY, NOVEMBER 20TH.

The Conference on Wednesday resumed the consideration of the proposed Electric Lighting Regulations. Sir Courtenay Boyle, K.C.B., again presided. The attendance of delegates was not quite so large as on the previous day.

Sir COURTENAY BOYLE said: I have carefully considered the very important representations made to me yesterday on the question of the definition of low pressure. The importance of that definition was made very clear to my mind by the arguments which were used yesterday. The points raised were highly technical and highly scientific, and I have come to the conclusion that it would not be possible for me to give definite or final advice to the Board of Trade as to their decision on the points that were submitted yesterday. I think probably it would be for the convenience of those interested in the matter if a decision was reserved for a short time, and if the Board of Trade were to appoint a small committee—say not exceeding, perhaps, three expert advisers—to carefully consider the scientific aspect of the question, and finally to make representations to the Board of Trade.

General WEBBER, and several others of those present, expressed their approval of the course proposed.

Sir C. BOYLE: Then I shall recommend that course to the Board of Trade.

On the proposed Regulation 29, which provides that "all metal conduits, pipes, or casings containing any electric line shall be efficiently connected with earth, and shall be so jointed and connected across all street boxes and other openings as to make good electrical connection throughout their whole length,"

Mr. CROMPTON said that the Institution of Electrical Engineers desired that the regulation should apply only in cases of high pressure.

Major CARDEW pointed out that it seemed to him that the point now being raised was dealt with in the next regulation.

Mr. CROMPTON, having referred to Clause 30, said he found that that was so, and his argument therefore fell to the ground.

On Clause 30, that "where isolated lengths of metal conduit, pipe, or casing are used for the protection of any electric line at road crossings or similar positions, there shall be interposed between such electric line and the conduit, pipe, or casing such additional insulating material as will prevent the possibility of any electrical charging thereof," the representative of the Manchester Corporation suggested that it would be very hard upon them if the regulation were passed in its present form, as they had a large number of cased lines, which had cost a great deal of money, and to alter which in compliance with this regulations would involve a great deal of expense.

Sir C. BOYLE: I think we may make this regulation a little more general, and simply require that sufficient precautions be taken to prevent the possibility of electric charging.

Clause 31 provided as follows:—"Where the conductors of electric lines placed in any conduit are not continuously covered with insulating material, they shall be securely fixed in position, and no unfixed material of a conducting nature shall be contained in the conduit. Adequate precautions shall also be taken to ensure that no accumulation of water shall take place in any part of the conduit, and to prevent any access of moisture to the conductors or the insulators; and the latter shall be so disposed that they can be readily inspected."

Mr. BAYNES, of St. Pancras, said that many of their mains were laid at a depth which would make it impossible to carry out the inspection in the way suggested by Prof. Kennedy. They had something like £40,000 worth of mains sunk, and it would be a most serious matter for them to have to alter them.

Sir C. BOYLE: Nobody ought to be more alive to the danger of allowing inflammable incrustation of insulators than the authorities of St. Pancras.

Mr. BAYNES: We have examined some of them recently, and found no incrustation, and there has been only one case of explosion.

Major CARDEW: We certainly found in one case that there had been a deposit on intermediate insulators; but I admit that it is not frequent.

Sir C. BOYLE, after further discussion, said they must have some precaution such as that embodied in this regulation; but he thought it would suffice if they made it prospective. Of course, it was desirable that undertakers should start at once to work up to that level of excellence as far as they could.

In answer to a question, Major CARDEW said it was intended by the new Regulations that there should be some external protection to the casing of an electric cable, to prevent people outside being brought into accidental contact with it. In the case, for instance, of high-pressure leads being brought inside a post, the idea was that the lead should be enclosed in a metallic casing. Steel armour would constitute a sufficient casing.

Prof. KENNEDY: It is important to know whether lines going by lamp-posts are included.

Major CARDEW: The lamp-post itself would form the outer casing of an armoured cable, but, of course, it must be connected with the earth.

Sir C. BOYLE remarked that the provision in question would be retrospective.

Digitized by Google

The Conference next proceeded to consider Regulations Nos. 33 and 34, which were as follows :—

(33) "Every high-pressure electric line transmitting more than 50,000 watts, or used for the supply of energy to transformers placed in street boxes, shall, except within the generating station, be entirely enclosed in strong metal casing efficiently connected with earth, and such casing shall not contain any low-pressure electric line."

(34) "High-pressure electric lines not intended to transmit more than 50,000 watts, may be enclosed either as provided in the preceding regulation, or in glazed stoneware casings properly laid and jointed in cement at a depth of not less than 2ft. below the surface of the ground and sufficiently protected against breakage."

Mr. CROMPTON proposed to substitute for the two draft clauses just mentioned the following, which he believed would accomplish all that the Board desired, and would be more workable :—"Every high-pressure electric line transmitting more than 50,000 watts shall, except within the generating station or sub-station, be entirely enclosed in strong metal casing efficiently connected with earth, or in stoneware or other suitable casing, and such casing shall not contain any low-pressure electric line unless this line is a concentric cable with the outer conductor earthed."

Sir C. BOYLE, after considerable discussion, remarked that it had been suggested to him that instead of adopting these two new regulations, they should go back to the old regulation known as No. 8.

Mr. CROMPTON: The proposal to go back to the old regulation meets our case.

Sir C. BOYLE: I prefer it.

Major CARDEW said that the only question in his mind was as to whether the limit of depth should not be 2ft. instead of 18in.

Sir C. BOYLE said he would follow what was the evident and general feeling—that they should drop out the two new clauses, and revert to No. 8 of the old Regulations.

The next Regulation (No. 35) considered was the following: "All street boxes which contain any vacant space shall be so constructed as to prevent any influx of gas or water either from the adjacent soil or by means of any pipes, and ample provision shall be made by ventilation or otherwise for the immediate escape of any gas which may by accident have obtained access to the box, and for the prevention of danger from sparking."

Sir C. BOYLE explained that this had only been put down as a basis of discussion. In regard to street boxes used for transforming chambers, he must have some further precautions, such as were agreed to at the Conference held some months ago. He did not want the regulation particularly in regard to ordinary street boxes, but it was a question whether it should not apply to very large street boxes, even if not used as transforming chambers.

Mr. GUNYON, for the London County Council, suggested that there should be a special clause in regard to transforming chambers and other large street boxes—say those of 1 cubic yard capacity. That would leave the smaller box on a different footing.

Mr. Crompton, Mr. Hammond, Prof. Kennedy and others thought that Mr. Gunyon's suggestion would be generally accepted—namely, that the regulation should apply only to boxes of not less than 1 cubic yard capacity.

Mr. HOLMES (on behalf of Liverpool) urged that if there was to be a limit of capacity, it should be 2 cubic yards instead of one. They had put these large boxes under the streets over ten years without any difficulty having arisen.

Sir C. BOYLE: We are not proposing in any way to limit the size of street boxes. We only want to provide that where they are large they shall be provided with sufficient ventilation. I think it will be generally acceptable that Clause 35 should apply only to street boxes containing transformers. We will consider Mr. Gunyon's suggestion, that a regulation should be made for the ventilation of other street boxes, which are of 1 cubic yard capacity.

The new Regulations 36 and 37 were agreed to, after some modifications.

A long discussion arose on Clause 38, which runs as follows :—

"All converting stations, or points in a system of distribution to which a high pressure supply is given from generating stations, and from which a low pressure supply is given to consumers, shall be established in suitable places, which are in the sole occupation and charge of the undertakers."

The general feeling appeared to be that the supplying undertakers ought to have the sole right of access to chambers, and Sir C. Boyle pointed out that the difficulty of occupation could be got over by the undertakers renting a room occupied by the chambers in the same way that they might rent a cellar in a person's house. Eventually, after hearing Prof. Ayrton and others on the subject, Sir C. Boyle admitted that there was great force in the objection which had been offered to this particular regulation, and thought that it would be better to drop it, and go back to the old regulation, No. 16.

Several other rules were then discussed and agreed to with certain amendments, and Sir C. Boyle consented to a proviso that undertakers should not be obliged to connect up to houses unless there was an insulation resistance of at least k/n megohms, k to be subsequently settled, n being "the number of points for taking of current," although on the other hand they *must* cut off connection if the insulation resistance fell below 5,000 ohms.

The regulations relating to arc lighting were next proceeded with, and Sir C. Boyle stated, in answer to a question, that they related only to the undertakers.

Clause 47 was passed without amendment. On Clause 48, that "arc lamps used in any street shall be so fixed as not to be in any part at a less height than 10ft. from the ground,"

Mr. HOLMES (Liverpool) said he had no objection if the regulation referred only to public lamps for street lighting, but he would point out that, by Liverpool Corporation regulations, consumers' arc lamps could now be fixed at 8ft. from the ground, and to raise them 2ft. would render them useless for their intended purpose—viz., lighting shop windows.

Sir C. BOYLE said that the regulation would be modified so as to read that *arc lamps used for public lighting* shall be fixed at 10ft. from the ground, and that lamps used for private lighting shall be fixed at 8ft. and screened.

Mr. BAYNES asked whether the Board of Trade would not also concede that public arc-lighting lamps should be allowed to be fixed at 8ft.

Sir C. BOYLE: No. I have given way on the private lamps. I must stick to 10ft. for public lighting lamps.

In Regulation 49, dealing with arc-lamp switches, Sir Courtenay Boyle, on the representation of a delegate, agreed to leave out, in Sub-section C, the words "by an inexperienced person."

On Clause 50, dealing with penalties, the TOWN CLERK of HULL said he was afraid the clause, as it stood, would result in throwing upon electric lighting undertakers responsibilities which primarily belonged to other companies or bodies. He did not think the Board of Trade in forming these regulations intended to confer an advantage upon a gas company at the expense of an electric lighting company. Assuming that an accident occurred, the person injured might not have regard to those who were primarily responsible, but come down upon the electric lighting undertaker. The undertakers did not object to a penalty for breach of the bye-laws; but they objected to regulations framed for the protection of the public being used for the purpose of shifting the responsibility for accidents from the shoulders of those who were primarily the cause to those of the electric undertakers, who were only liable in a secondary degree. The person injured ought to rely on the common law remedy against those who were primarily responsible. He would suggest that these words should be added: "And nothing in this regulation shall impose upon the undertakers any liability to make compensation in respect of any damage or injury which may be caused by reason of such default."

Sir C. BOYLE said his counsel advised him that the regulation did not shift any responsibility. There was, however, some difficulty in the matter in the mind of his counsel, and he would only now say he would deal with it in the best way he could.

The regulations as to supply were speedily disposed of. The proposed notice of a week to commence a supply was reduced to 48 hours on the suggestion of Mr. Hammond. In the clause for the maintenance of a constant supply, the proviso was amended so that the permission to temporarily discontinue the supply might be given not only for the purposes of testing "or for any other purpose connected with the efficient working of the undertaking," and "at such intervals as may be thought expedient."

On the provision that "the variation of pressure at any consumer's terminals shall not under any conditions of the supply which the consumer is entitled to receive, *nor at any time*, exceed 4 per cent. from the declared constant pressure, *whether such variation be due to the resistance of the service lines or apparatus belonging to the undertakers, or to any action or effect produced by such apparatus, for which the consumer cannot be shown be responsible, or, partly to any variation of pressure in the distributing mains from which the supply is taken*,"

Sir C. BOYLE consented to omit the words italicised by us.

This concluded the business of the Conference.

Sir C. BOYLE said it was his pleasing duty to thank very heartily the various representatives who had attended the Conference, in the name of the Board of Trade, for the manner in which they had raised their objections and the courtesy with which they had pressed them.

On the motion of Alderman GIBSON, Manchester, seconded by Alderman MYLES, Bolton, a cordial vote of thanks was passed to Sir Courtenay Boyle.

The Conference then separated.

DINNER TO MR. W. T. ANSELL.

A dinner was given at the Holborn Restaurant, London, on the evening of the 14th inst. to Mr. W. T. Ansell, the traffic superintendent of the Eastern Telegraph Company, to celebrate his jubilee in the telegraph service. The chair was occupied by Mr. J. Denison Pender, the Managing Director of the Eastern Telegraph Company, on whose immediate right sat the guest of the evening, and the company included Sir Henry F. Mance, Major A. Wood, Prof. D. E. Hughes, Mr. C. E. Spagnoletti, Mr. W. H. Preece, F. J. Griffiths, W. H. Burman, H. C. Forde, H. A. Taylor, A. Le Neve-Foster, J. Gavey, F. Higgins, J. Hookey, W. W. Howell, J. Jenkin, F. Lucas, D. Sinclair, W. O. Smith, J. W. Wilkins, H. D. Wilkinson, F. Webb, Captain Hampton, N. Jauralde, and F. Deering, as well as a large number of Mr. Ansell's colleagues and personal friends in the telegraph service. The committee who had charge of the arrangements carried them out with complete success, and had the satisfaction of receiving a well-deserved vote of thanks.

The usual loyal toasts having been duly honoured,

The CHAIRMAN proposed the toast of "Telegraphy." It was not, he remarked, the toast of the evening, but it was one of very great importance. He would not go into the details of the progress of telegraphy, as there were so many gentlemen present who had followed, step by step, the advancement of this great enterprise, which now made so notable a mark in the world. The satisfaction of America and of Canada when they were able to speak with the old country some years ago with one cable was extreme, and the same means of communication had since been extended to all parts of the world, and not only by one cable, but by many. He was connected with some of the companies which at the

Digitized by Google

present time maintained the communication between Canada, America and Australia through Great Britain, but he did not wish in any way on that account to throw cold water on that other great project, the Pacific cable. He thought, however, he was justified in saying that before this enterprise was undertaken those who had been identified by their past with the telegraph world, whether by land or sea, should be listened to, and listened to attentively (hear, hear). It was easy to lay a cable at the bottom of the sea, or to put anything into the ocean; but when a cable was put into the ocean they wanted to be able to get hold of it again. The sounding wire had not yet fathomed the depths in some parts of the Pacific where it was proposed to lay the cable. He therefore thought the gravest consideration ought to be given to the proposal before it was undertaken. The contractors' business was to lay a cable and then hand it over to the Company concerned to work it, but he thought that if the contractors were asked to name their price for maintaining the Pacific cable, the amount required would show what the undertaking really meant. Cable men must not and did not forget the value of the land lines, which he believed were 2,500,000 miles in extent, and which took up the cable work and distributed it for the submarine companies. They also collected the cable companies' work, and handed it over to them in all parts of the world. Were it not for the network of these great land lines he feared the cable companies would not hold the high position they now occupied. They had both followed the flag wherever trade had sprung up. The public might say with truth that the cable companies received subsidies from the Governments. They did not, however, get subsidies to begin with, and it must be remembered that the cable companies had shareholders to face and to pay dividends to. It was not exactly the same thing with the Government lines, but he was bound to thank—and he wished to take that opportunity of doing so—those who held positions under the Government, and with whom the cable companies had daily dealings, for the courtesy and assistance which they always received from them (hear, hear). The great enterprise of telegraphy was due to science and capital. Science could not do without capital, and capital in this case could not do without science. He regretted that he was not a scientist, and he must admit that capital occasionally lagged, which was never the case with science. Science would on one day do that which would revolutionise the working of their cables, and even their land lines, but it would on the next day begin again with the view of improving what was regarded as perfect. He believed that if science and capital would, as in the past, set aside any little jealousies which might arise between them, there were even greater things before them than those which had been already realised (hear, hear). He was proud that the name he bore had been associated with the beginning and the development of this great industry. He felt that he could not pay a higher tribute to those who had led the way in the enterprise than by urging the younger men not only to do their duty, as those before them had done, but to endeavour to do even better; and by means of science and their own energy try to keep Great Britain in the pre-eminent position which she had always held, scientifically and commercially, throughout the world. It was by such work, by such energy, that Mr. Ansell occupied the proud and honoured position in which they saw him that night (loud cheers).

Sir H. F. MANCE traced the progress of submarine telegraphy from its earliest days, telling more than one amusing incident in connection with the defects in the lines and the mistakes which consequently arose. When he looked back over his past life he thought that his experience might possibly be considered unique, for he had assisted in the making of the cable, submerging it, working it for many years afterwards, then having to repair it, and eventually having to lay a new cable in its place. He mentioned various names identified with the progress of the enterprise, and remarked that it was the great commercial genius of Sir John Pender to which was attributable so much of the success of submarine telegraphy, while their honoured guest of that evening might be permitted to stand among them as the representative of the submarine telegraphs throughout all parts of the world. At all stations the name of Ansell was familiar as household words (cheers).

Prof. HUGHES, F.R.S., replied for scientific telegraphy, observing that instruments and discoveries had often been made in advance of their time. Thus the duplex was invented in Germany, England, and the United States many years before the condition of the lines would permit of its use. Bain early showed them how to transmit and receive over 1,000 words a minute, but the inherent qualities of their lines did not allow of this speed even at the present time. Ever since his first connection with practical telegraphy in 1856 nothing had surprised him more than the gradual and sure improvement of the lines throughout Europe and America. He believed this constant progress was due in a great part to the use of more scientific methods and exact measurements. Scientific telegraphy had ever been on the alert to combat any phenomena which would act in a deleterious manner against the rapid transmission of signals. He would not weary them by enumerating the phenomena that scientific telegraphy had to observe. Electricians and engineers had worked faithfully, and had made wonderful progress during the last 50 years, and he was convinced that science would not rest until our lines and instruments were as near perfection as possible. Mr. Ansell commenced his career in the age of steam, but he now found himself in the age of electricity. His name and services were well known throughout the civilised world to all connected with scientific telegraphy, and he was sure that they all wished him strength and health to continue his career (hear, hear, and cheers).

Mr. C. E. SPAGNOLETTI also responded to the toast, referring more particularly to the progress of the land lines and to the high perfection of working to which they had now been brought. He had lately been connected with an instrument which appeared to want a little more attention —the phonopore. It had not been favourably received, and some might laugh at it, but it had done excellent work, and he felt assured that if it were only placed in the hands of good people to work with opportunities of trying experiments, all difficulties in connection with it would be overcome. It would be an excellent instrument in case of emergency. There was no doubt in his mind that Englishmen would still continue to carry out all the improvements which were brought forward periodically for perfecting the lines. He wished long life to his old friend and old chief, Mr. Ansell, from whom he had learned a great deal.

Mr. W. H. PREECE, C.B., afterwards proposed "The Guest of the Evening." It was, he said, exactly 44 years since he (Mr. Preece) made acquaintance with a fine, bold, splendid Roman hand, whose memoranda and notes used to be deciphered without any difficulty by him in the small office in the West Strand. From a note which he received on the previous day he had been pleased to see that there was not a trace of faltering in that fine Roman hand (cheers). Mr. Ansell commenced his career before he (Mr. Preece) did, but for 44 years their careers had run side by side. In 1845 Mr. Ansell commenced with that *alma mater* of all telegraphists, the old Electric Company, incorporated in 1846, and from 1846 to 1856 he remained in a position of trust and responsibility, acting as one of those pioneers who succeeded in establishing telegraphy in this country on a sound financial basis (hear, hear). The Chairman had remarked that science and capital must always be found in this enterprise. That had been so. He could speak from experience of it. In the south of England he was the scientific fellow, and Mr. Ansell was the capital fellow (hear, hear and laughter). Mr. Ansell remained the same capital fellow, but he himself lost his science on a memorable evening 39 years ago, when he was informed that the time between Southampton and Berlin had gone back nearly two hours (laughter). His career as a lecturer had thus been cut short. He never knew the culprit, who, however, had acknowledged himself that night [referring to an incident recounted by Sir H. Mance]. He was one of those who believed that the finest incentive to progress was opposition, as illustrated by the great struggle they had had in this country to push on telegraphy, telephony, and the electric light. Unfortunately, in the time of progress, Mr. Ansell's health broke down, and he retired for a short time to the Greek Archipelago, and took charge of the cables in the Levant; but that only led, with a slight interrupton, to his subsequent entry into the service of the Eastern Telegraph Company —that great octopus, whose feeders were found all over the world (hear, hear and cheers). He was sure they would all join with him in wishing long life and prosperity to Mr. Ansell. With all his faults—they were very few—they loved him still. He had a kind heart, he was a cheering companion, and if there was anyone in discomfort or distress, and wanting assistance, he had only to go to Old Bill Ansell, and with that impetuosity which they had no doubt all seen, he would help a friend out of the greatest difficulty (cheers).

The toast was drunk with enthusiasm amid continuous cheering, followed by the singing of "He's a jolly food fellow."

Mr. W. T. ANSELL, who was again warmly received, in reply assured them that, although the expression was hackneyed, that was the proudest moment of his life. He did not know how to express his feelings in acknowledging the unprecedented honour which they had done him, and he had not been aware until that moment how many valued friends he had gained in all parts of the world. Perhaps he might say without egotism that it was a fitting end to a career such as his (Voices, "No, no," and "You have not done yet.") At the time to which his old friend, Mr. Preece, had referred, the incorporation of the old Electric Company in 1846, there were 84 of them on the muster roll—he had a printed list of them Of those 84 men, who were the pioneers of telegraphy of the world, five were still living, but he himself was the only one who was in harness. There was one old friend of his present who was his senior in telegraphy, although he had left the career of telegraphy since 1850—he referred to Mr. Wilkins (cheers). It was a source of great gratification to him to find Mr. Wilkins among them that evening, because although, as he had said, Mr. Wilkins abandoned telegraphy to resume his profession, it was to that gentleman and his principals that they were indebted for the first steps which were taken in what had subsequently been, and still was, the most important and the greatest boon to the world that this or any century had seen (hear, hear). Mr. Preece had sketched his (Mr. Ansell's) early career in connection with the land line telegraphs. The first 25 years of that career were spent almost entirely, excepting the short time he was in the Levant, in connection with land telegraphy. It was his fate to be pushed to the front, and he was in the van of nearly every line that was erected in England. In the same way it had been his fate in the last 25 years of his life to be connected with submarine telegraphy and to find himself in the van of progress. He had mentioned his friend Mr. Wilkins, and as regarded himself they knew that his connection with telegraphy began in November, 1845. There was, however, still one gentleman prominently before the public, he was happy to say, who ran him very closely in active harness—he alluded to his honoured Chairman, Sir John Pender (cheers), who in 1847 first associated himself with telegraphy in connection with the British Electric Company, and to whom the world was indebted for the greatest civilising boon that had yet been seen. Fifty years ago, before the days of ocean steamers and of the Suez Canal, it took six months for a merchant in London to get a reply to his letters and to know that his orders for a shipment had been executed. Of course, everything was dear. The merchant's capital was locked up for months, and, naturally, the consumer suffered. They now found that what formerly took six months only took six hours (cheers). He was proud to say that he was still serving the man to whose indomitable pluck, perseverance, and prescience the world was indebted for what no man yet could properly appreciate. But for Sir John Pender they would never have had submarine telegraphy in the advanced position it now occupied. Although he was deeply grateful to them for the honour that had been done him, he must still be allowed to give honour to whom the greatest honour was due (cheers). He was proud

Digitized by Google

of the assurance of his friend on his right (Mr. Preece) that his efforts to benefit his fellows had been appreciated, and he desired to thank them again from the bottom of his heart for their kindness, and for the unprecedented honour which they had conferred upon him (loud cheers).

The CHAIRMAN afterwards presented Mr. Ansell with a handsome gold watch and chain, and a clock and ornaments *en suite*, together with a beautiful diamond brooch for Mrs. Ansell. They all congratulated Mr. Ansell on having arrived at 50 years' service, and on being in a hale and hearty condition to undertake, he hoped, many years' further work. Mr. Preece had referred to having worked in harmony side by side with Mr. Ansell for so many years, and, speaking on the part of the companies with which he (the Chairman) had the honour of being associated, he wished to say that it was their desire to work in harmony with others wherever it was in their power to do so. The testimonial which he had presented to Mr. Ansell was a token of appreciation and goodwill from all parts of the world. He had a bundle of telegrams in his possession; he was not going to detain them by reading them, but he might say that they came from every part of the world for Mr. Ansell.

Mr. ANSELL again feelingly acknowledged the kindness which had been displayed towards him.

Mr. DRAPER afterwards proposed "The Chairman." Mr. Pender, he said, had always identified himself with the interests of the staff both at home and abroad, and it was due to his good feeling, his energy, and his imperturbable good humour that he was enabled to carry on his very complicated work for the companies with which he was associated. In the name of the Committee, and in his own name, he desired to thank Mr. Pender for the cordial relations that existed between them and him, and the Directors for the confidence which they reposed in their officers.

The toast having been cordially drunk,

The CHAIRMAN acknowledged it in appropriate terms, and incidentally observed that he was always not only willing but pleased to associate in anything which could bring the different sections of the telegraph service in this country together, that they might act as one man and maintain their position against any opposition that might attack them in any part of the world (cheers).

Major WOOD proposed "The Committee" who had carried out the arrangements for the celebration. He desired to endorse all that had been said that night. He could assure the Chairman, on his own part and on the part of those whom he represented, that they were really most anxious that the telegraph interests should work unitedly in every possible way.

Mr. T. A. BULLOCK, in responding for the toast, remarked that the Committee had, as they could see, done everything possible to make the gathering a success, and referred to Mr. A. R. Hardie and Mr. W. Hibberdine, as having done a large share of the hard work of the Committee.

The company shortly afterwards dispersed.

LONDON COUNTY COUNCIL.

At the weekly meeting of the London County Council on Tuesday it was agreed, on the recommendation of the Building Act Committee, that consent should be given to the erection of electric lighting buildings on the south side of Bowling Green-walk, Hoxton, on the application of the Vestry of Shoreditch, subject to the usual conditions imposed by the Council as to the works being commenced within six months, &c.

National Telephone Company.

It was reported by the Bridges Committee that the National Telephone Company had applied for permission to lay a cable along Waterloo Bridge. The Company proposed fixing a 2½in. cable upon the last cornice of the bridge and within a segmental galvanised iron casing, 9in. in width at the base by 5½in. in height. The casing was to be flanged at the base and to be attached to the cornice bymeans of Lewis's bolts let into the granite. As so large a casing would probably interfere with the architectural lines of the structure, the Committee were of opinion that the Company should be restricted to the use of a 3in. tube, as at Hammersmith Bridge. With regard to the attachments, those should be made by narrow iron straps attached at intervals to the base of the plinth of the bridge, with the object of providing a means of drainage beneath the pipes. As to the rent to be paid by the Company, the Committee suggested that an annual rent of £10 should be charged, which was the same as that charged for the cable across Hammersmith Bridge. They recommended: "That the National Telephone Company be allowed to lay a cable across Waterloo Bridge on the terms and conditions before mentioned, to be embodied in an agreement to be prepared by the solicitor, and subject to the work being carried out to the approval of the engineer of the Council."

Mr. ROBERTS said that that was a matter which he hoped the Chairman of the Committee would take back. It was a proposal to lay a 3in. cable. The original proposal was a monstrous suggestion to fix a 9in. by 6in. pipe. That was not a question of saving the ratepayers' money. Waterloo Bridge was, he might say, the best bridge they hadin London, and there was already one tube there for the Council's own purposes. Should they allow the Company to save money by the laying of that tube and spoiling the bridge architecturally? Why should not the National Telephone Company put the tube in the road, for there would be very little space required? He thought it was somewhat strange that the Company did not approach them when the roadway was being made; but of course it was a question to the National Telephone Company as to how they could best carry out their work; but it was no part of the work of the Council to allow them to spoil one of the best bridges in London.

Mr. EMDEN said that whilst they wanted to keep the bridge from being disfigured he did not think they should encourage the placing of the wires under the roadway. Nothing could be worse for the general public than having the middle of the public road pulled up. He did not think the placing of that small tube on the cornice of the bridge would disfigure it in the eyes of anyone unless they looked specially for it. If the matter went back there might be some other bridge on which it might be carried over.

Mr. PEARCE (Chairman of the Committee) said that in view of what was evidently the feeling of the Council, he would take the recommendation back.

The proposal to take the report back was then agreed to.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *November 1, 1895.*

Electrical Speculation in Philadelphia.—The Quaker City has not been noted as a speculative centre, but recent events would seem to indicate that its character in this respect is undergoing a change. Some months ago a storage battery company was organised there with a capital of $13,500,000, and a few weeks ago the stock reached 70, but has since fallen to below 50. Mr. W. W. Gibbs, the promoter of the United Gas Improvement Company, of the Heisler system of electric lighting and of the Welsbach light, is at the head of the enterprise first referred to—the Electric Storage Battery Company. Speculation in all of the above stocks (except the Heisler, which system has apparently been abandoned) has been so rife that the name of the "American Kaffirs" has been applied to them. Still more recently, the same promoter organised a syndicate which has obtained control of the Edison Illuminating Company of Philadelphia, and it is announced that the profits under the new management will be largely increased from the sale of exhaust steam, for which purpose an extensive system of piping is to be laid throughout the business districts. The capital stock of the Edison Company was $2,000,000, and that of the new concern is $10,000 000.

November 8, 1895.

A New Conduit Electric Railway.—The Metropolitan Street Railway Company of Washington (D.C.) has nearly completed equipping about four miles of double track with a modified Budapest conduit system, after the designs of its chief engineer, Mr. A. N. Connett. The insulators, instead of being horizontal as at Budapest, are vertical, and consist of a corrugated porcelain cylinder in a metal cup, which latter is secured by a set screw in the top of the conduit. The conductor consists of a 6in. T bar, to the vertical face of which chilled shoes secured to a plow similar to a cable grip will be held by a light spring pressure. A voltage of 500 will be used, instead of 300 as at Budapest. A manhole alongside of each insulator will make these easily accessible for examination and repair. The feeders are carried in terra-cotta ducts between the tracks.

Storage Batteries.—The phenomenal success of the Electrical Storage Battery Company of Philadelphia in its stock operations has caused storage battery companies to flock to the front. The above Company last week purchased the Pumpelly-Sorley battery of Chicago, paying, it is said, a price that was very advantageous to those interested in the Chicago Company. The Reed Electric Company of Philadelphia was incorporated a few days ago, and will manufacture a Planté cell invented by Mr. C. J. Reed, the well-known electro-chemist. The specific points in the Reed cell are its light weight and the extremely small amount of time required for charging, it being said that the cell can be fully charged in 40 minutes; it is also claimed that the cell will stand a very high rate of discharge on account of its extremely large surface and depth of active material. Among other companies entering the field are the Haschke Storage Battery Company of Chicago, and the Hatch Storage

Digitized by Google

Battery Company of Philadelphia, but no details have as yet been printed concerning the construction of their cells. In connection with storage batteries, we may say that the Madison-avenue street car line of New York city has during the present week placed two storage batteries cars on its line, using chloride cells.

CORRESPONDENCE.

STREET LIGHTING BY ARC LAMPS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have glanced through Mr. Hesketh's translation of M. Blondel's very interesting articles, being already familiar with the original. There are several points which I should like to discuss, but I will confine myself for the present to only one or two.

The curve (Fig. 8) on page 848, correctly reproduced from the original, appears to me to be wrong. It should not run up to a sharp point; and supposing that it is fairly correct between the one lux and eight, it ought to curve over and stop at about 12. Figs. 5 and 6 appear to me to be inaccurate also. I cannot understand how so sharp a peak as that given in Fig. 15 is possible. It is true that it represents an artificial and not a natural distribution, and means that the light was strongly concentrated at a point below the lamp. But the polar curve in Fig. 13 gives no indication of any such vertical concentration. The natural curve is given correctly in Fig. 4 and in Fig. 17. The expression "curve of horizontal illumination," a true enough translation from the French, is an unfortunate one. The author means illumination of (or upon) a horizontal plane, but those who have not studied the subject, or who only run rapidly through the articles, might think that the illumination due to horizontal rays is intended. This is an instance of ellipsis which is already too common in scientific writings. People use "potential" instead of "difference of potential" merely to save time, or because they are lazy. I have been guilty of using "candle-foot" instead of "candle at a foot," but will do so no more. The undue compression of *ars longa* into *vita brevis* can only be accomplished by scamping.

The calculated isolux, or as I have called them, contour, or isophotal curves, which the author has borrowed from M. Maréchal's book, are very pretty, but one or two actually observed plans would have been much more interesting. Plans of this kind, from actual measurements in Queen Victoria-street and in Whitehall, were given in my Paper read before the Institution of Civil Engineers in 1892. That Paper covered a good deal of the ground traversed afterwards by M. Maréchal and M. Blondel, and when the latter alludes to "Mr. Trotter's article, which is by no means a mere repetition of mine," I can only suppose that he has been rather carelessly translated. My Paper was read on May 10, 1892, and M. Blondel's articles only appeared this year. He probably means repetition neither in the sense of imitation nor of subsequence, but of coincidence. He did not see a copy of my Paper until his own had been written. I regard the coincidence of our independent work as a very valuable confirmation of the results at which we have arrived.

One mistranslation of a more serious character catches my eye, and appears in the first paragraph on page 89, the word *foyer* being translated "lamps" in some places and "lanterns" in others. It is generally safe to translate this comprehensive word (in this connection) as "source of light," and one is tempted to shorten this into "light" or "lamp." But to translate it as "lantern" entirely misrepresents the author's meaning. The translation runs: "At first sight everything seems to resolve itself in favour of large lanterns." The use of large globes for small lamps is a well-known tradesman's trick. For exhibition purposes a 6-ampere arc in a 20in. globe seems to the more or less intelligent public as good as a 10-ampere arc in a 14in. globe. The useful illumination, of course, is not so great, but who cares for useful illumination except MM. Blondel, Maréchal, Wedding, Wybauw, Palaz, Weissenbruch, and a few other photometrists?—Yours, &c.,

A. P. TROTTER.

[With regard to the translation of M. Blondel's French we cannot do better than quote the original, which is as follows:—"Les lecteurs que ce sujet interesse auront donc grand profit à lire entièrement le mémoire de M. Trotter *qui ne fait pas double emploi avec le mien.*" The italics are our own, and these words were translated accurately as above. As to the word *foyer* being sometimes translated "lantern" and sometimes "lamp," Mr. Trotter is quite right in pointing out the incorrectness of the former term, which was in nearly every instance avoided.—ED. *E.*]

GRAPHICAL METHOD OF CALCULATING MAGNETIC FORCE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The method mentioned by Mr. Everett in his letter in last week's issue was the first way of doing this that suggested itself to me when I wanted to make the planimeter do the required integration. On considering it, however, I saw that in practice it would be an inaccurate method, involving as it does the measurement of angles as well as lengths. It is well known to practical men that lengths can be measured much more accurately than angles, so I discarded this method in favour of one involving only the measurement of lengths. He, by the way, takes no precautions about his dimensions, so gives it a specious simplicity. I think that if he will look at my Paper again and remember that in a practical formula it is of the utmost importance to keep the dimensions correct, he will see that I have not made it needlessly complicated. The measurement of angles, also, comes into his other method, making it less accurate than the method I gave.

I am amused at the persistent quoting of Ampère's formula

$$F = i\int \frac{d\theta}{r}$$

by Mr. Everett in his letters to you; in time some people may be led to believe that he was the first discoverer of it.—Yours, &c.,

ALEXANDER RUSSELL.

Faraday House, Charing Cross-road, W.C.,
November 15, 1895.

HIGH VOLTAGE SUPPLY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With reference to the discussion on the subject of raising the E.M.F. of continuous-current supply stations (Hull, St. Pancras, &c.), I beg to suggest the following method, which I am advocating in similar cases. Allow a substantial discount to all consumers taking a supply at the higher voltage, raising the price to others if necessary. This may be applied to all alike or to old consumers only, new ones being supplied only at the higher voltage. In the case of a large consumer having more than one meter the change may be made gradually, leaving one circuit on the low tension till the old lamps are used up as far as possible. A small allowance may be made for old lamps, to be used up in the station, where there will be no advantage in using the higher pressure (except for experiment) until the change is complete, and even then any pressure may be taken from the batteries. When, by this method, the bulk of the consumers have been induced to make the change, it may be enforced on the remainder with comparatively little friction. It is of some importance to arrive at the easiest method of making a change which will put continuous-current stations more on a level with alternating as regards capital outlay, and enable them to supply power economically for tramways from the same plant as for lighting purposes.—Yours, &c.

126, Prenton-road, Birkenhead, ARTHUR J. HILLS.
November 19, 1895.

THE PRESIDENCY OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: There can be little question that the majority of Members and Associates of the Institution of Electrical Engineers have cordially endorsed the opinion set forth in last week's electrical Press; but it has since become apparent that

Digitized by Google

the Council intend to persist in the nomination of Sir David Salomons to a position which he and they must fully know should only be occupied by a man of great distinction in electrical science and engineering. All of us appreciate how much the Institution of Electrical Engineers owes to the Institution of Civil Engineers, and the intercourse between the societies must be mutually useful. It is to be hoped that in the coming election the Electrical Engineers will take a leaf from the book of the parent society and follow their policy in such a matter as this, for it would be humiliation indeed if, in the same year as the Civil Engineers have appointed the most distinguished engineer in England (if not outside of it) to be their chief, the Council of the Electrical Engineers succeed in electing to a similar position a most worthy and benevolent dilettante. It will be pitiful, too, if the Council succeed in putting pride in its own procedure above the interests of the Institution. It has already become quite apparent that, however ingenious and influential may be the support of the Council's nominee, the justification of its choice is feeble enough. The Council must further know that its action will be opposed by a large part of the youth and energy of the profession, who have a strong ally in time, and who most firmly believe in the principle for which they are contending. It might conceivably be the great privilege of some of those young engineers to write the biographies of the distinguished gentlemen who now control the destinies of the Institution, and it would be sad to have to chronicle the notable dis-service the promoters of Sir David's candidature are rendering to their own constituents. This movement has been carried on so far with a great desire to avoid personalities and to leave unimpaired the dignity of the Institution. This spirit will be continued through the contest which has been challenged if it is clearly remembered that the opponents of Sir David have no other motive than the preservation of the high scientific renown which previous presidents have won for an Institution which has already become a factor of no inconsiderable importance in the industrial development of the Empire.—Yours, &c.,

ALFRED E. MAVOR.

32, Victoria-street, S.W.

LEGAL INTELLIGENCE.

Hunter and Jack v. Kuisopp.

The plaintiffs, who are electrical engineers at Glasgow, were successful in the Sheriffs' Court at Linlithgow, in an action against the defendant, a draper of Bathgate, who was sued for the sum of £36. 4s. 7d., the balance of contract price for an electric light installation amounting to £166. 6s. 8d. The defendant contended that plaintiffs asked permission to fit up on the outside of his premises two arc lamps for the inauguration of the installation. The lamps did not turn out satisfactory, and in January last one of the brackets from which the lamps were suspended broke, and in its fall smashed one of the defendant's shop windows and injured three persons, to whom the defendant had had to pay £30 as compensation. He attributed the accident to carelessness in fitting up the lamps and the bracket being insufficient to bear the strain of the lamp. Defendant urged that plaintiffs were bound to repay him the £30 paid as compensation.

The Sheriff decided that plaintiffs, having completed the work, are entitled to payment of the sum sued for. The lamps, he says, which were at first fitted up were changed for two lamps of a different pattern; and one was removed and placed in a higher position by the defendant without the sanction of the plaintiffs.

Poole and White (Limited) (in Liquidation) v. South.

In the City of London Court, before Mr. Commissioner Kerr, this action was brought to recover £37. 7s. 10d., for fittings and other electrical appliances supplied to the defendant, Mr. Harry South. The defendant did not dispute the delivery of the goods, but set up an agreement with the plaintiffs to take electrical goods in contra account. Mr. South, the defendant, said that he had done business with the plaintiffs for a great many years. In September, 1894, their representative, a Mr. Larkin, agreed that he should receive electrical goods from the plaintiffs as a set-off against his account, as the plaintiff Company was then in liquidation. That was the second liquidation, and as he could not get money for the goods which he had previously supplied he took goods instead. As a matter of fact there was a balance due to him. For the plaintiffs it was urged that Larkins had no authority to make the arrangement set up by the defendant, as the Company was at that time in the hands of a man named Kelly, who had been made receiver and manager by the debenture holders. There was no agreement in writing.

Mr. Commissioner KERR said there was no necessity for that. If there was to be a flat contradiction he would send the case for trial before a jury. Ultimately the case was referred to the Assistant Registrar for consideration and report.

Imperial Telephone Company (Limited) v. Electric Novelty Syndicate (Limited).

This action was heard in the City of London Court, and was for the recovery of the sum of £3. 13s. for goods sold and delivered to the defendants. Mr. Gilbert, who appeared for the defendants, said that his clients were in negotiation with the plaintiff Company for the purchase of their patent. At the suggestion of Mr. Watson (who was in fact the plaintiff Company) a telephone was put up in the defendants' office for experimental purposes, but the defendants declined to purchase the instrument, and had asked the plaintiffs to take it away. Evidence was given that the defendants had purchased the instrument, but the case was adjourned for the attendance of Watson.

Harrison v. Estelle.

In the Westminster (London) County Court, last week, the plaintiff, an electrical engineer, sued the defendant to recover 15 guineas, balance of account, in respect of work done. Work had been done to the extent of over £100. There had been payments on account, but there was still due the amount now claimed. The defendant appeared to be under the impression that she was not liable to pay for certain alterations and extras which had been carried out to her instructions, which, she contended, were rendered necessary owing to the plaintiff's own mistakes. The judge decided that the defendant was right so far as some of the items were concerned, and should therefore give judgment for the plaintiff for nine guineas and costs on that sum.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

SPECIAL NOTICE.—The 1895 (thirteenth) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is READY. In addition to the old well-known features of the book, which are brought up to date, a quantity of new and useful matter has been added, rendering the book more than ever indispensable to the Electrical, Engineering, and Allied Trades. Price 7s. 6d., post free 8s. 3d., abroad 9s.

The Edition for 1896 is in active preparation, and orders for Advertisements and Subscriptions (5s. 9d. post free, abroad 6s. 6d.) should now be sent in. The usual circulars, &c., are now being sent out.

NEW BOOKS AND EDITIONS.

The following New Books and Editions of "THE ELECTRICIAN" SERIES can be obtained of the Booksellers or direct from the Publishing Offices:—

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett *(now ready)*. Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"THE WORK OF HERTZ."—By Dr. O. J. Lodge, with many original illustrations, price 2s. 6d. nett, is now ready.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

A LARGE-SHEET TABLE, giving full particulars of the Electricity Supply Stations throughout the Kingdom, can now be supplied mounted on stout board, with cord for hanging. Price: Varnished, 3s. 6d.; Unvarnished, 3s. —each post free. A Map showing positions of Supply Stations throughout the country is mounted on the back of the Table, and a Coloured Map of Metropolitan Electric Lighting Areas and a large sheet of Electricity Supply Statistics are also mounted on some copies, the price of which complete, post free, is 5s.

A SHEET TABLE showing Total Capital Outlay and Receipts and Expenditure for the year 1894 of the Statutory Electric Supply Undertakings of the Metropolis is now ready, printed on thick paper. price 6d.

A SHEET TABLE giving similar particulars in relation to Provincial Statutory Electric Supply Undertakings is now ready, printed on thick paper, price 6d.

"ELECTRIC MOTIVE POWER."—A new work, by Mr. Albion T. Snell with this title, is now ready, containing the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d. post free (abroad 11s.).

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by Messrs. W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

Digitized by Google

TENDERS INVITED.—The Corporation of Durban require tenders for cast-iron service boxes, cast-iron junction boxes, cast-iron manhole frames and covers, and ornamental cast-iron arc-lamp pillars. Conditions, &c., from the Consulting Engineer, Mr. W. H. Radford, Pelham-chambers, Nottingham, and tenders must be sent in to Messrs. Webster, Steel and Co., 5, East India-avenue, London, E.C., by the 27th instant.

——— The Swansea Corporation invite tenders for (1) the supply and erection of destructor and electricity supply station buildings; (2) for the erection of a chimney shaft, 150ft. high, with all necessary foundations and accessories; and (3) for the supply and erection of a dust destructor, including eight destructor furnaces and four water-tube boilers, with all necessary flues, dampers and accessories. Tenders, addressed to the Town Clerk (Mr. Jno. Thomas), The Guildhall, Swansea, must be in by 4 p.m. December 6th.

——— The Magdeburg Direction of the Prussian State Railways invites tenders for the supply of 25¾ tons of galvanised iron wire and 1,500 porcelain insulators. Tenders to the Königliche Eisenbahn Direction, Knochenhaueruferstrasse I, Magdeburg, by 26th inst.

——— The Secretary of State for India is inviting tenders for the supply of electric light plant, railway stores, &c. Tenders to Mr. J. Parker, India Office, Whitehall, S.W., by December 10th.

——— The Markets Committee of the Manchester Town Council invite tenders for the supply of two dynamos for the Foreign Animals Wharf, Mode Wheel. Tenders by December 2nd to the Town Clerk.

——— Tenders are invited for the electric lighting of New Cardiff Technical School. Tenders to the Secretary, University College, Cardiff.

TENDERS ACCEPTED.—The following tenders were received by the authorities of the Cancer Hospital, Brompton, London, for electric light wiring and fittings at the hospital:—

Name of Firm.	Wiring.			Cutting away & making good.			Fittings, exclusive of lamps.			Totals.		
	£	s.	d.	£	s.	d.	£	s.	d.	£	s.	d.
Drake & Gorham (*accepted*)	309	0	0	25	0	0	86	19	0	420	19	0
Crompton and Co.	668	0	0	45	0	0	107	8	0	820	8	0
Rashleigh Phipps and Co.	523	0	0	20	0	0	115	5	6	658	5	6
H. M. Leaf	310	0	0	25	0	0	99	11	6	454	11	6
Sotheby and Co.	293	10	0	25	10	0	77	14	0	397	14	0

Mr. Morgan Williams, Assoc.M.Inst.C.E., is consulting engineer for the installation.

——— The Harrogate Town Council, at their last sitting, accepted the amended tender of Messrs. Paterson and Cooper for the wiring of the public baths for the electric light. The tender of Mr. C. O. Dawson for erecting electric bells was also accepted.

——— The Saltash Town Council have decided to accept the tender of Mr. T. Martin for lighting the town by electricity from January 4th next. The cost is to be £2. 10s. per light.

——— At the last meeting of the Cheltenham Town Council it was decided to accept Messrs. Siemens Bros. and Co.'s tender for a switchboard at £165 and regulating resistance for £12. 10s.

SALES BY AUCTION.—Our advertisement columns contain particulars of the sale by auction, by Messrs. Wheatley Kirk, Price and Goulty, on Thursday, December 5th, of the entire contents of the works premises at Broadway, Walham Green, S.W., in the occupation of Messrs. Russell and Co., who are giving up business. Catalogues can be obtained from the auctioneers, and from Messrs. Russell and Co., 11, Queen Victoria-street, E.C.

——— The Reading Electric Supply Company having completed their new electricity station, Messrs. Wheatley Kirk, Price and Goulty give preliminary notice of the piecemeal sale by public auction, at an early date, of the entire contents of the Company's old station, the Island, Reading, comprising engines, boilers, combined lighting sets, dynamos, &c. Further information is given in our advertisement columns.

CHANGE OF ADDRESS.—We are invited by the publisher of *Electricity* to insert the following:—

"DEAR SIR: If not too much against your own interests I shall esteem it a great favour if you will mention in your columns that, owing to the constant increase in the sale of this paper and the technical works published by me, I have had to move to more commodious offices on the first floor of No. 11, Ludgate-hill, London, E.C."

APPOINTMENT VACANT.—The Lighting Committee of the Wolverhampton Corporation require a clerk and canvasser in the office of the borough electrical engineer. Salary £100 per annum. Applications to Mr. F. Harman Lewis, Borough Electrical Engineer, Town Hall, Wolverhampton, by Saturday, December 7th next. Further particulars appear in our advertisement columns.

DISSOLUTIONS OF PARTNERSHIP.—The partnership business of electrical engineers hitherto carried on by Messrs. E. Hodgson, A. Blackburn and J. Walker, under the style of Blackburn, Walker and Co., at Toft's Mill, Cleckheaton, Yorks., has been dissolved. The business will be carried on under the same title by Messrs. A. Blackburn and J. Walker.

LIQUIDATIONS.—Mr. E. Wilding, liquidator in the matter of Poole and White (Limited), forwards us a summary of the liquidator's accounts from March to September, 1895, which shows that the estate is becoming smaller by degrees and beautifully less. The balance brought forward in March was £520. 19s. 11d., the balance carried forward in September £165. 2s. 6d., £350 of the difference being swallowed up in remuneration to the liquidator. There is nothing on the face of the summary to show what has been done for this very considerable sum, except the disbursement of a few pounds in "sundry expenses."

——— In the failure of W. J. Kelly (the representative of the debenture-holders in Poole and White, Limited) a return has been made which shows receipts £5, payments £7. 12s., assets *nil*. Mr. E. Leadam Hough, the Official Receiver in this matter, intends to apply "within 21 days" for his release. This may be taken as an official intimation that there is nothing in the estate for the liquidator or the creditors.

——— At the County Court, Worcester, on Wednesday, before Sir R. Harington, the examination of the Directors and officers of the New British Electrical Installation Contractors (Limited) took place, the examination being conducted by Mr. Luke Sharp, the Official Receiver. The secretary, Mr. J. W. Hill, stated that the Company was promoted by Messrs. Griffiths and Millington. He as secretary had no salary, and kept no books except the register of members and the share ledger. The prospectus of the Company, of which fifty or sixty thousand copies were circulated, "was made as attractive as possible to the public." One of the ideas was to put electric launches on the River Severn, but no launches were ordered. He admitted that a paragraph extolling the prospects of the Company was written by himself and appeared in the Worcester papers, in which the prospectus was extensively advertised. The promoters had lost over £3,000. Mr. J. Duce, who was General Manager and Secretary to the old Company, said that the whole of the contents of the prospectus was true, and that had capital been subscribed for the old Company it would have been a great success, but they could not get the money in. After the examination of Mr. Millington, the Chairman of the Company, who said that if everyone had worked as hard as he had done the result would have been different, the examination was adjourned till December 18th.

——— A meeting is to be held at 3, Hammet-street, Taunton, on December 20th next, at 3 p.m., to receive an account of the winding-up of the Taunton Electric Light Company (Limited).

——— At an extraordinary general meeting of the members of the Collier-Marr Telephone and Electrical Manufacturing Company (Limited) on the 13th inst., it was decided to wind up the Company voluntarily, and Mr. Wm. Frost, 77, King-street, Manchester, was appointed liquidator.

——— Creditors of the Printing Telegraph and Construction Company of the Agence Havas (Limited) (in liquidation) must send in particulars of their claims to Mr. W. H. King, 13 and 14, Basinghall-street, London, E.C., by December 31st next.

INTERNATIONAL ELECTRIC SUBWAY COMPANY (LIMITED) (*in Liquidation*).—A meeting of shareholders was recently held for the purpose of deciding what steps should be taken to renew the British and Continental patents owned by this Company. The shareholders decided to contribute no money for this purpose. The liquidator, Mr. C. W. Grimwade, 38, Coleman-street, E.C., therefore invites creditors to provide the necessary money for the upkeep of the patents. The amount required is £25. Should the creditors not be disposed to adopt the suggestion, the liquidator proposes to take the usual steps to close the liquidation of the Company.

HOOKHAM ELECTRICITY METERS.—Messrs. Chamberlain and Hookham are prepared to receive applications from first-class agents in the United States and foreign countries for the Hookham meter.

"PRITCHETT" ACCUMULATORS.—We have received a price list of these accumulators, which are of the Planté type. It is claimed that the construction of the plates renders them capable of being discharged at very heavy rates without buckling or loss of active material. The method of connecting the plates to the lug allows for any positive plate to be removed and a new one substituted without the section being taken out of the acid. The list of prices received is for batteries of from 1 to 21 plates. These cells are manufactured by Messrs. Pritchetts and Gold, of Soho-square, London, W., who will supply full particulars on request.

CATALOGUE.—Messrs. Crompton and Co. (Limited) have sent us a copy of their new price list of electrical heating and cooking apparatus, for which five diplomas and four gold medals have already

Digitized by Google

been awarded to the firm. Judging by the variety and size of the apparatus, cooking and heating by electricity are making considerable progress; indeed, the cleanliness, convenience and general superiority of the electrical over every other methods have only to become widely known to be very generally adopted by the public.

ELECTRO-HARMONIC SOCIETY.—A "ladies' night" is announced for Saturday, the 30th inst., at the St. James's Hall Restaurant (Banquet Room), Regent-street, W., at 8 o'clock.

ASHTON-UNDER-LYNE.—At the last meeting of the Town Council it was decided to refer the electric lighting question to the General Purposes Committee.

AUSTRALIAN LAND LINES.—Telegraphic communication has been established between Perth (Western Australia) and Yalgoo, and is expected to materially assist in developing the mineral resources of that extensive district.

BANGOR (IRELAND).—A special meeting of the Town Commissioners will shortly be held for the purpose of considering the question of the advisability of applying for a Provisional Order.

BELFAST.—The head offices of the Belfast Banking Company have been fitted throughout for the electric light by Mr. J. H. Greenhill. Theinstallation consists of four 3,000 c.p. arcs and 72 incandescents. The work has given the greatest satisfaction to the Directors.

BLOEMFONTEIN.—The Town Council have just signed a contract with an electric lighting firm for the lighting of the town by electricity.

BRAY.—At the last meeting of the Town Commissioners it was decided that a clause be inserted in the Provisional Order now sought by the Commissioners to enable them to sell electricity for motive-power purposes.

BURTON-UPON-TRENT.—In an application to Parliament by the Corporation notice is given of application for powers to manufacture, sell and hire apparatus and fittings for the electric light. ——The Town Council have decided to apply for powers to extend their electric lighting area.

BURY ST. EDMUNDS.—The electric lighting plant recently put down by Messrs. Crampton and Co. for the lighting of Abbeygate-street is now in full working order, current being supplied to shops and offices in the locality at 7d. per unit. The first quarter's working has, it is stated, proved successful and profitable.

'BUS LIGHTING.—In London several attempts have been made to light the public omnibuses by electricity, but apparently with only a small measure of success. While the owners of the "Star" line of 'buses and the Westminster-Liverpool-street 'buses, not owned by the London and General Company, continue to use the light, other lines have returned to the old and very bad system of lighting by means of the dismal oil lamps. At Nottingham, Mr. E. Mann, the owner of a well-known line of 'buses, has recently constructed a new class of vehicle, into which the electric lamps are fitted. An application has been made to the Electric Lighting Committee of the Corporation for permission to have the batteries filled at the Corporation's works. This is the first time the electric light has been introduced into public vehicles in Nottingham.

CAMBERWELL (LONDON).—The General Purposes Committee recommend the Vestry to give their consent to the application of the County of London and Brush Provincial Company for a Provisional Order.

CANADA.—The Government is negotiating for the extension of the telegraph to Belle Ville, viâ Bonne Bay, Newfoundland. This line will be of great benefit to shipping interests, as it will enable vessels from England to be reported the fourth day out.

CARDIFF.—The Lighting Committee of the Corporation have signified their appreciation of Mr. W. H. Massey's services as consulting engineer in connection with the electric lighting scheme by unanimously passing the following resolution :—

"This Committee desire to place on record their appreciation of the valuable and important services rendered to the town of Cardiff by Mr. W. H. Massey, M.Inst.C.E., as consulting engineer in connection with the laying down of the system of electric lighting within the borough under the Cardiff Electric Lighting Order, 1891, and also to convey to Mr. Massey their sincere thanks for the conspicuous ability displayed by him in the carrying out of this great work, and of the many intricate and important details in connection therewith."

CHELTENHAM.—At the last meeting of the Town Council the Electric Lighting Committee reported that they had received applications for 4,540 8 c.p. lamps, of which 4,134 were connected. Alderman Norman, in moving the adoption of the minutes of the Committee, said they were anxiously awaiting the sanction of the Local Government Board for borrowing an additional sum of £10,000 for extension purposes.

CHURCH LIGHTING.—Messrs. Drake and Gorham, of 66, Victoria-street, S.W., have been entrusted with the contract for lighting St. Paul's Church, Deptford.——St. John's Church, Paddington, has just been fitted for the electric light by Messrs. Rashleigh Phipps and Co. Two hundred incandescents will be used.——The Welsh Presbyterian Church, Princes-road, Liverpool, is now lighted electrically.——The authorities of Redcliff Church, Bristol, are so satisfied with the temporary electric lighting of the building that it has been decided to make a permanent installation. Between 300 and 400 8 c.p. lamps will be used. The work is to be completed before Christmas.

DUBLIN.—The *Freeman's Journal* on Wednesday contains a sketch map of the proposed electric tramway extension in Dublin and an account of the scheme.

DUNDEE.—At the last meeting of the Town Council it was decided to light the Free Library electrically.

EDINBURGH.—At the last meeting of the Town Council a letter from Mr. M. Holroyd Smith, offering to introduce an electric system of traction on the Edinburgh tramway lines, was referred to the Lord Provost's Committee for consideration and report. It was also agreed to extend the electric light mains from the Post Office to Regent-terrace.

ELECTRIC ATHLETIC ASSOCIATION.—The annual *conversazione* and distribution of prizes in connection with this Association was held last week at the Holborn Town Hall under the presidency of the Duke of Norfolk, Postmaster-General. The chief officials of the postal telegraph department were present. A vote of thanks to His Grace for presiding was proposed by Mr. Spencer Walpole, and seconded by Mr. Fischer.

SMOKING CONCERT.—Mr. F. J. Wray presided at the first smoking concert of the season of the cricket club of the City Electric Athletic Association, formed in connection with the City of London Electric Lighting Company, which took place at the Masons' Hall Tavern last week. The Chairman was supported by Mr. J. Cecil Bull and about 130 members and friends.

FULHAM (LONDON).—The Electric Light Committee of the Vestry have instructed Mr. F. H. Medhurst to prepare a report on and draw up a scheme for the electric lighting of this district.

GAS COMPANIES AND THE ELECTRIC LIGHT.—The *London Gazette* contains notices from the following gas undertakings of an intention to apply to Parliament for powers to supply electric current for lighting and other purposes: Bournemouth Gas and Water Company, Bexhill Water and Gas Company, Guildford Gas Light and Coke Company.

GENOA.—The *Daily News* of the 20th inst. is responsible for the statement that the Syndic of Genoa has suspended the work of all the tramways in that city owing to a number of accidents which have recently happened, but fortunately, it is stated, without much damage to passengers.

HALIFAX.—A syndicate has been formed for the purpose of constructing and working a network of electric tramways in this town.

HAMPSTEAD (LONDON).—At the last meeting of the Vestry the matter of extending the electric light mains from Heath-street to The Grove was referred to the Lighting Committee for consideration and report. On the recommendation of the Committee, the Clerk was instructed to make official complaint of the gas lighting.

HAPTON (LANCS.).—This is probably the smallest village in the Kingdom lighted by electricity, both public and private lighting, and the contract with Messrs. Simpson Bros. has just been signed for a further six months' supply of current.

HARROGATE.—The Town Council have decided upon a further extension of the electric light mains.

HARWICH.—The report of the Public Health Committee of the Town Council sets out the terms upon which the Town and Village Electric Light and Power Company offer to take over the Harwich Order, and to instal the electric light in the borough without cost to the local authorities. The Company proposes to enter into a contract for the supply of current lighting for 14 years at 4½d. per unit, and to pay the Corporation £300 by an allowance of 10 per cent. discount off each quarter's account for public lighting until the £300 is absorbed. This proposal was considered at the last meeting of the Council, and, by the casting vote of the Chairman, was agreed to.

JOHANNESBURG (S.A.R.).—The Sanitary Board have decided to adopt the "Brockie-Pell" arc lamp, and Messrs. Johnson and Phillips recently received an order for upwards of 50 lamps.

KETTERING.—A meeting of the District Council has been held to consider the advisability of applying to the Board of Trade for a Provisional Electric Lighting Order. A Committee recently appointed to consider the subject has reported to the Council that the proposed compulsary area was too large and should be somewhat curtailed; that a reasonable estimate would be for an equivalent of 2,500 8 c.p. incandescents and 20 arcs as a start; that the estimated cost of an installation to provide current for this number of lamps and to include accommodation for extension to machinery, &c., would be £9,500, with annual up-keep charges,

Digitized by Google

including interest and payments, £1050. 10s., the estimated income being slightly in excess of this sum. The meeting of the Council on Thursday was called specially to consider this report. Mr. Mobbs said that the Committee had gone very carefully into the subject, and had obtained statistics, &c., from all places in the country which compared with Kettering. The Committee found that the electric light was installed in no less than 110 districts in the kingdom, and that a similar number of places had the work either in progress or under consideration, and the Committee therefore considered they were justified in recommending the Council to apply for the Order, although he personally was not in favour of at once starting the works. They had had an offer from one firm to put down the whole of the necessary plant, and to hand over to the town authorities a complete installation at a payment of 3 per cent. on the outlay for a period of 30 or 40 years. Of course, they could obtain the Provisional Order, and could drop it altogether subsequently if they chose. It was stated that the local gas company had no intention of opposing the introduction of electric light unless the application for an Order was made by a private company. The Chairman of the Council, Mr. J. I. Stockburn (also chairman of the local gas company) considered the scheme premature, and did not think it desirable that the Order should be applied for at the present time. Mr. M. T. Gorman, upon whose suggestion the Committee had been formed, went fully into the advantages of the electric light over gas, and strongly urged the Council to proceed with the matter. The adoption of the Committee's report was carried with a good majority.

KIDDERMINSTER.—A Company is about to be formed for constructing electric tramways between Kidderminster and Stourport. It is proposed that the first line should commence opposite the Town Hall buildings, pass along Oxford-street, Bridge-street and New-road to Stourport, and terminate in Bridge-street, Stourport; the second line is to commence at the intersection of Spirit-lane and Comberton-road, and connect in Oxford-street with the line to Stourport; while a third tramway would run westward of the line in the New-road. The Company will apply for Parliamentary powers in the next session.

LECTURES.—Prof. S. P. Thompson delivered the Saturday Public Lecture at Toynbee Hall, London, E., last week, the subject being "The Magnetic Effects of an Electric Current." The lecture was illustrated by experiments and gave great pleasure to a large audience, who cordially thanked the Professor at the close.——Mr. W. A. Douglas Rudge delivered a lecture at the Plymouth Technical Schools, the subject being "Warming and Lighting." The lecture was illustrated by some Crompton electric heating and cooking apparatus, and the use of this apparatus was practically demonstrated. A large audience took great interest in the lecture.

LEEDS.—At the last meeting of the City Council the report of the Highways Committee recommending the engagement of Dr. J. Hopkinson to advise them on the electric traction question was adopted.

LONDON COUNTY COUNCIL.—At the meeting of this Council on Tuesday, Mr. Roberts objected to the recommendation of the Bridges Committee giving permission to the National Telephone Company to lay a telephone cable across Waterloo Bridge, and proposed that the recommendation should be referred back. This was seconded by Dr. Longstaff, and was approved.——Owing to ill health Mr. de la Hooke, the much-respected Clerk to the London County Council, has been compelled to send in his resignation, to take effect in March next. It is stated that the post is to be thrown open to competition to solicitors and barristers-at-law, at a salary which has been fixed at £2,000.

LLANDRINDOD WELLS.—At the last meeting of the District Council a letter was received from the Town and Village Electric Supply Company offering to tender for the electric lighting of the district. The Clerk was instructed to obtain particulars.

LLANELLY.—The Borough Council recently appointed a committee to negotiate the terms as to the sale of their Provisional Order to Mr. J. C. Howell, and it is now stated that the parties have agreed upon the conditions of the transfer, and that the Committee will present a report on the matter to the Council at their next meeting.

NECHELLS (NEAR BIRMINGHAM).—The first meeting of the Committee appointed to consider the proposal of the Birmingham Central Tramways Company to erect an overhead electric tramway was held on Wednesday, and a further meeting is to be held on Monday next to consider a reply from the Tramways Company, giving particulars of the system proposed to be adopted on their Nechells route.

NESTON AND PARKGATE (CHESHIRE).—A meeting of the principal ratepayers of these districts was held last week for the purpose of considering the report on the electric lighting question recently prepared by Mr. Marsh for the Lighting Committee of the District Council. The report was discussed at considerable length, and it was finally decided to call another meeting to further consider the matter.

NEWPORT (MON.).—The local gas company have already become alarmed at the progress of electric lighting in this town, and have appealed to the Corporation for longer notice and other benefits before electric lamps are allowed to take the place of the old gas lamps. The Corporation show an amicable spirit, and have agreed to continue to pay for the gas lamps until December 7th, and to give three months' notice in future before discontinuing gas lighting in any district of the town.

PROVISIONAL ORDERS.—The Corporations of Bath, Cork, Huddersfield and Liverpool, and the District Council of Keswick, give notice of their intention to apply to the Board of Trade on or before December 21st, for Provisional Orders under the Electric Lighting Acts 1882 and 1888.

RAILWAY STATION LIGHTING.—The electric light has just been installed at the Durban Railway Station.

RAWMARSH (YORKS.).—A proposal having been made for the construction of a tramway between this town and Rotherham, the District Council have appointed a Committee to consider the matter, more especially in reference to the question of the adoption of an electric system of traction for the proposed tramways.

SHEFFIELD.—The London and Provincial Tramway Syndicate have prepared a scheme for the construction of electric tramways in Sheffield, which it is ultimately proposed to extend to Rotherham.

SKATING.—The Commons Committee of the Cambridge Town Council at the last meeting recommended that the application from the Cambridge Electric Supply Company for permission to erect poles to carry wires to enable the Company to supply current to the skating ground in the Grantchester Meadows should be granted. As, however, no plan was submitted to show the position of the poles, the matter was referred back to the Committee for reconsideration.

STROUD.—The formal opening of the Stroud Telephone Exchange took place on Monday.

ST. LUKE'S (LONDON).—A proposal from the County of London and Brush Provincial Company to light the public thoroughfares of this parish is before the St. Luke's Vestry.

SUNDERLAND.—The Board of Guardians have under consideration the electric lighting of the new infirmary. Messrs. W. & T. R. Milburn are the Board's advisers in this matter. The lighting by electricity of the main workhouse building has been referred to the House Committee for consideration.

TELEGRAPH WIRE AND APPARATUS EXPORTS.—The export trade in telegraph wire and apparatus connected therewith shews during October a falling-off compared with the preceeding month, the value only amounting to £39,769, against £45,268 in September. Compared with October last year, the returns shew an increase of £17,507. The exports for the ten months ending with October amounted to £423,206, compared with £1,326,856 in the corresponding period of last year and £1,012,305 in the first ten months of 1893.

TELEPHONE EXTENSION.—The National Company have under consideration a proposal to establish a telephone exchange at Bedford.

THEATRE LIGHTING.—A considerable extension has been made to the electric lighting at the St. James's Theatre, London, by Messrs. Rashleigh Phipps and Co.

THE METRIC SYSTEM.—Mr. A. J. Balfour, the First Lord of the Treasury, received a deputation from Chambers of Commerce, the "New Decimal Association," and other bodies, on the subject of the metric system on Wednesday. The deputation recommended (*a*) that the metric system of weights and measures be at once legalised for all purposes; (*b*) that after a lapse of two years the system be rendered compulsory by Act of Parliament; (*c*) that the system be taught in all public elementary schools as an integral part of arithmetic, and that decimals be introduced at an earlier period to the school tuition than is the case at present. Sir A. Rollit, M.P., who introduced the deputation, pointed out that the deputation represented an immense body of public opinion, and it was agreed that the present system was obsolete and disastrous to British trade. Sir S. Montagu, M.P., said that if the United Kingdom adopted the system the United States would also do so. Mr. Balfour gave his adhesion to the recommendations (*a*) and (*c*) without hesitation, but pointed out that the recommendation (*b*) required careful consideration, and that he could see there would be very great difficulty in compelling every class in the community to suddenly alter its habitual practice in the weights and measures in which it deals. He was pleased to learn that all the great engineering firms used the metrical system, which, in his opinion, was the only rational one. To the observation made by one member of the deputation, that the metric system was excluded from the manufactures undertaken by the Government, he thought this was a matter well worthy of consideration, and he would consult with his colleagues to see if anything could be done to meet the wishes of the traders in this respect. He would especially consult with Sir J. Gorst to see if something could not be done to spur on the teaching of this system in the schools, and to so familiarise the imagination

Digitized by Google

of the children with the system which they might have to use in later years.

TIME SIGNALS.—It is proposed to add the port of Belfast to the list of ports in the United Kingdom provided with time signals worked by electricity. The towns at present include Greenock, Dover, Southampton, Portland, Liverpool, Edinburgh, North Shields, Dublin, Deal, Portsmouth, Swansea, Dundee, Leith, Cork and Queenstown.

TRAMWAY PROVISIONAL ORDERS.—Notice is given in the *London Gazette* of the intention on the part of the following companies and Municipalities to apply to the Board of Trade for powers to use electric or other motive power on the tramway systems under their respective control:—Hull and Plymouth Corporations, Pwllheli West End and Belfast Street Tramways Companies.

WANDSWORTH.—The Electric Lighting Committee of the Board of Works has notified its approval of the plans for the proposed electric light supply station of the County of London and Brush Provincial Company.

WINDSOR.—In reference to the decision of the Town Council to put their Electric Lighting Order up to tender, a discussion took place at the last meeting, at which Alderman Dyson hoped that the matter would be fully considered before this step was finally taken. Councillor Barber asked whether any particular system (two-wire or three-wire) had been decided upon. It was pointed out that the object of the advertisement was to enable the Council to obtain full information on the subject, and place the same before the Council at a later date. A letter was read from the Thames Conservancy stating that the proposal to use the water power at Windsor Weir for electric light purposes could not be entertained.

WITHINGTON.—The District Surveyor is preparing an estimate of the cost of lighting the Town Hall electrically.

WOKING.—A report by the Sanitary and Lighting Committee on the subject of the lighting of this town was discussed at the last meeting of the District Council. The Committee's report was adopted, and it was decided to advertise for tenders for lighting the district by electricity or gas.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

October 15, 1895.

19,340. P. W. T. DAVIES. London. Improvements relating to electric cars.

19,353. J. JAHNSSON. London. Improvements in electric gas lighting apparatus.

19,374. S. E. COX. London. Improvements in incandescent electric lamps and the method of making the same.*

October 16, 1895.

19,380. G. H. NISBETT. London. Improvements in the manufacture of insulated cables.*

19,389. C. B. CRAWSHAW and R. KENNEDY. Bradford. Improvements in tempering the wire points of textile cards electrically, and in apparatus therefor.

19,402. W. E. HEYS. Manchester. Improvements in and connected with return circuits for electric railways and tramways. (G. Kapp, Germany.)

19,442. A. HIRSCH. London. An improved method of and apparatus for welding by electricity and for other purposes.

19,461. H. B. COX. London. Improvements in thermo-electric generators.*

October 17, 1895.

19,503. C. ADAMS-RANDALL. London. Improvements in telephonic apparatus.

19,509. J. A. MCMULLEN. London. Improvements in alternating electric current transformers.

19,527. J. M. URQUHART and W. H. DINGLE. London. Improvements in high insulation fuses or cut-outs for electric lighting.

October 18, 1895.

19,551. W. D. REID. London. An improvement in conduits for conductors of electricity or other mains.

19,577. P. LINDSAY and J. BRADIN. Glasgow. Improvements in incandescent electric lamp-holders.

19,605. J. V. SHERRIN. London. Improvements in and connected with dynamos and the driving of same and electric motors for the driving of vehicles and machinery.

19,628. A. J. BOULT. London. Improvements in or relating to electric burglar alarms and the like. (R. Damseaux, Belgium.)*

October 19, 1895.

19,647. W. H. WILLATT. Hull. Improvements in secondary batteries.

19,669. A. SCHANSCHIEFF. London. Improvements in secondary battery plates.

19,670. A. SCHANSCHIEFF. London. Improvements in secondary batteries

19,696. J. E. WOODRIDGE. London. Improvement in electric light display systems. [Date applied for under Patents, &c., Act, 1883, Sec. 103, July 8, 1895, being date of application in United States.]*

19,734. COUNT A. DE DIXON and C. BOUTON. London. Improved means or apparatus for electrically igniting petroleum and other like motors.

19,745. J. KÖRNER. Liverpool. Improvements in and in the manufacture of plates for electric accumulators or secondary batteries.

October 22, 1895.

19,815. C. B. WHITE. London. An electromagnetic apparatus for actuating railway brakes and switches. (The St. Louis Brake Company, United States.)*

19,828. R. HEATHFIELD and W. S. RAWSON. London. Improvements in electrolytical apparatus.

19,832. A. G. NEW and A. J. MAYNE. London. Improvements in connection with electrical propulsion.

19,833. A. G. NEW and A. J. MAYNE. London. Improvements in connection with the electrical propulsion of vehicles.

19,837. T. E. ADAMS. London. Improvements in electric arc lamps.*

19,838. T. E. ADAMS. London. Improvements in electric arc lamps.*

19,839. A. DE PUYDT and M. PONCIN. London. Improvements in dynamo generators or motors.

19,860. J. DEVONSHIRE. London. Improvements in regulating electric motors. (W. B. Potter, United States.)*

19,861. J. DEVONSHIRE. London. Improvements in three-wire electric railways. (W. B. Potter, United States.)*

19,862. J. DEVONSHIRE. London. Improvements in dynamo electric machines. (E. Thomson, United States.)*

19,863. J. DEVONSHIRE. London. Improvements in regulators for alternating currents. (C. P. Steinmetz, United States.)*

October 23, 1895.

19,934. C. A. BURGHARDT and G. RIGG. Manchester. Improvements in a process and apparatus for the electrolytic production of metallic zinc and metallic copper from zinc ore containing copper, and oxygen gas as a bye-product.

19,947. C. MORADELLI. London. Improvements in electric contact devices.*

19,973. W. J. DAVY. London. Improvements in or connected with electric lamps.

October 24, 1895.

19,989. J. W. FLETCHER. Stockport. An electrical "tell-tale" or watchman's recorder.

19,992. C. BARLOW. Glasgow. Improvements in the method of laying an electric cable for tramways or railways, and the means of communication between the conductor and the car.

20,047. THE EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY (LIMITED), and A. WOODLEY. London. An improvement in the caps of incandescent electric lamps.*

20,048. F. E. ELMORE. Leeds. Improvements in or pertaining to electrically-driven pumping apparatus.

20,071. A. PHILIPPI. London. Improvements relating to electric railways.

20,073. S. O. COWPER-COLES. London. Improved means to be employed in the production of sheets or strips, or equivalent forms of metal, by electro-deposition.

October 25, 1895.

20,127. F. E. ELMORE. London. Improvements in apparatus for the manufacture electrolytically of tubes and other articles of circular section.

20,131. P. OPITZ and W. PETSCHEL. London. An improved manufacture of secondary or storage battery plates.

20,132. J. H. DUNN and J. PARSONS. London. Improvements in generating gases or steam by electricity from water, oil, or other suitable material.

20,164. S. O. COWPER-COLES, M. ULCOQ, W. M. GUTHRIE, and C. R. G. SMYTHE. London. Improvements in or connected with the production of metal, in sheets or other form, direct from zinc ores, applicable in part for use in the electrolytical deposit of metals generally.

October 26, 1895.

20,215. E. S. BOYNTON. Wolverhampton. Improvements in tubular galvanic batteries.*

20,214. E. S. BOYNTON. Wolverhampton. Improvements in double-fluid galvanic batteries.*

20,216. E. S. BOYNTON. Wolverhampton. Improvements in galvanic batteries.*

20,237. THE EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY (LIMITED), and C. F. PROCTOR. London. An improvement in electric safety fuses.

NEW COMPANIES, STATUTORY RETURNS, &c.

TRAMWAYS CONSTRUCTION COMPANY (LIMITED).—This Company was registered on November 14th, with a capital of £100,000, in £10 shares, to enter into contracts for the construction, repair and maintenance, and to construct, equip, repair and maintain tramways and other roads or ways to be used for traction by electricity or other agency, bridges, subways, waterworks, &c., including the laying of pipes for the distribution of electricity and for telephonic communication, and to work and carry on any electric or other tramway, telephonic, telegraphic, or electric lighting system. The first subscribers are: J. B. Concannon, H. W. Jefferson, H. Oppenheim, J. Morris, and H. Marnham, 500 shares each; H. R. Beeton, 300 shares, and W. Haldinstein, 100 shares.

CITY NOTES.

MEMORANDA.—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver, 30⅝d. per oz. (Nov. 21st). Consols (2¾ per cent.) 105⅞–106⅛ for money, 105⅞—106⅛ for account; 2½ per cent. 103½—104 (Nov. 21st). Stock Exchange Settling Days: Consols, Dec. 2nd; Stocks and Shares Continuation Day, Nov. 26th; Ticket Day, Nov. 27th; Pay Day, Nov. 28th.

BRITISH ELECTRIC TRACTION (PIONEER) COMPANY (LIMITED).—Letters of allotment in this Company's recent issue of 5,000 shares have been posted. The applications were, it is stated, largely in excess of the capital required.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The *Financial News* of the 19th inst., in a critical review of the position of the above Company, calls attention to the comparatively small interest which investors are taking in electric railway enterprises in the metropolis. Attention is called to the decrease in expenditure from year to year and to the satisfactory improvement in the dividends paid by the Company. But what is, perhaps, of most interest to investors is the fact that at 40-42, the figures at which the shares at present stand, the yield is nearly 3 per cent., and the stock may certainly be classed with many of the best home railway issues "with a practically certain prospect of a notable increase before long in dividend and capital value."—The traffic returns of this Company for the week ended November 17th (on which day the railway was partly closed for alterations at King William-street Station) were £958, against £972 in the corresponding week of 1894, a decrease of £14. The total receipts for the half-year amount to £17,616, against £17,691 for the corresponding period of 1894, a decrease of £75.

EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY (LIMITED).—Our advertisement columns contain the numbers of 381 Five per Cent. Mortgage Debentures of £100 each in this Company, which have been drawn for payment at par on January 1st next by Messrs. Barclay, Bevan and Co., 54, Lombard-street, E.C.

GESELLSCHAFT FUR ELEKTRISCHE UNTERNEHMUNGEN (BERLIN).—A meeting of this Company will be held on the 28th inst. for the purpose of considering a proposal to increase the capital of the Company from 15,000,000 to 30,000,000 marks.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 17th inst. amounted to £1,028. The amount for the corresponding week last year was £881; increase, £147.

RUSSISCHE GESELLSCHAFT FUR EXPLOITATION ELEKTRISCHER KRAFT.—A Company bearing this title, and with a capital of 500,000 roubles, has just been formed in St. Petersburg. Herr N. Demtschinsky is president.

ST. JAMES'S AND PALL MALL ELECTRIC LIGHT COMPANY (LIMITED). The recent issue of £20,000 Four per Cent. Debenture Stock by this Company, offered to the existing shareholders at 2½ per cent. premium, was, we learn, largely over-subscribed.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended November 15th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,243.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the half-month ended November 15th are £2,120, against £1,994 in the corresponding period of 1894. The July receipts, estimated at £3,488, realised £3,577.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861—1878.

No. 915. [Vol. XXXVI. No. 5.] FRIDAY, NOVEMBER 29, 1895. PRICE SIXPENCE.

NOTES.

On the whole, approximate justice has been done in the action Fareham Electric Light Company (Limited) *v.* Fareham Urban District Council, a report of which will be found in another column. The local authority, several members of which were more or less interested in the Electric Light Company, decided, by a narrow vote, just previous to the elections, to purchase the electric light undertaking. The elections resulted in a majority adverse to the purchase scheme and and the new Council consequently refused to go through with the bargain. Hence the lawsuit in question, which has resulted in a verdict for the Company with £3,800 damages. It is well that the principle of the continuity of municipal liability should be vindicated, but we should have preferred to have seen it vindicated with less to be said for the other side.

It has been said that a man's views, when he believes them to be so absolutely correct that express them when, where, and to whom he will they cannot but be acceptable, are almost sure to be half wrong. We earnestly hope that this dictum does not apply to Mr. Sam. Mavor and his views on concentric wiring, though he most certainly has not failed to insist in season and out of season on the pre-eminent virtues of this system; and he has now wound up his crusade at the Institution of Electrical Engineers by a slashing indictment of double-wiring, wood-casing and crockery ware. If strong language were synonymous with strong argument there could be no discussion of this vigorous Paper. The question would be straightway settled for all time by its mere perusal. As it is, however, strong language by a strong man is an excellent prelude to a warm exchange of opinions, and we anticipate an informing debate, and shall look forward with some curiosity to the defence which we have no doubt will be made by the advocates, or if there be none left, by the sellers of the type of electric light fittings so unsparingly denounced.

The question opened up by this matter of house-wiring is an exceedingly wide and difficult one. It is without a doubt to the general interest of the industry, and, in the long run, to the interest even of competing wiring contractors, that good work should be put in. The problem is how to attain this desirable end without killing the goose that lays the golden eggs; that is to say, how are we to reconcile the small householder, who is generally a tenant, to the increased *first* cost? The owners of big West-end mansions, hotels, factories, &c., can afford the luxury of a consulting engineer, and will not look askance at a 20 per cent. bigger bill than they were led to expect. One might reasonably have anticipated that the rules of the various fire offices would have effected all that was required, but apparently fear of competitors is greater than fear of fires. Hence stringent rules are made, but leniently enforced. In the same way the rules of the electric supply companies are largely neutralised by considerations of a similar character and a desire not to frighten away intending consumers. Hence the strongly-expressed wish at the recent Board of Trade Conference that our great regulation machine should turn out a set of house-wiring rules and see to their enforcement, thus securing uniformity and safety. An admirable idea, which only suffers from the disadvantage that the Board of Trade has no power or desire to issue minute regulations of the kind.

Then, again, the sweet simplicity of the concentric system resides largely, if not entirely, in the outer being earthed. The objections of fire offices having been overcome, buildings served by isolated plants can now be wired on this plan. The Board of Trade, however, still remains obdurate with regard to the earthing of the middle wire of a three-wire system, and the development of concentric wiring with the outer earthed is, therefore, to a large extent barred. Could not the expert committee of three, which is to assist that Department in defining "low pressure," also assist it in the equally important question of the earthing of the neutral wire? Is it to be or not to be? We quite agree that it is better to bear the ills we have than fly to others we know not of; but meanwhile, Board of Trade or no Board of Trade, three-wire engineers assert that their currents *will* "turn awry." Would it not be as well to definitely ascertain if there be in reality any danger in recognising and legalising this state of things? The questions raised by Mr. Mavor's Paper are, therefore, as we have said, numerous, important and far-reaching, and we trust the discussion on his paper and on the one by Mr. Bathurst, which loudly proclaims the virtues of "interior conduit" wiring, will tend to their elucidation.

The type of steam engine which Mr. P. W. D'Alton has recommended for the new plant recently erected at Deptford is a somewhat novel one to this country, although we believe that in Germany the particular arrangement of cylinders

Digitized by Google

therein adopted is not uncommon. A glance at the illustration of the engine, which we publish this week, might suggest that it is a type of marine engine; but it will be seen that the engine differs from the standard marine pattern, in having its three cranks driven by three tandem compound engines. In our opinion this possesses, for alternator driving, a distinct advantage over the side-by-side compound or triple-expansion arrangement, inasmuch as it tends to maintain the regularity of the crank effort at all loads. With a side-by-side triple-crank engine, though the distribution of steam may be regulated ever so nicely at full load, there will be irregular driving at light loads. This is due to the fact that, though at full load the cylinders may share the work equally between them, the duty will be divided when the load falls, with increasing disproportion between them. As a consequence, alternators driven by such engines will not infrequently cause unsteadiness in the light at low load, even though the light may be faultless at other times. Of course, it is possible to provide side-by-side cylinders, each with a separate variable expansion gear, which will equalise the duties at all loads; but such gears are not commonly used, and in electric light stations they would probably be found to be too complicated. With a tandem arrangement the same expansion gear will actuate both cylinder distributions.

While speaking of valve gears, we are reminded that the new engine introduces a fresh type of gear into the Deptford station, where until lately the Corliss gear reigned supreme. The recent addition is provided with piston valves for the high-pressure cylinders and ordinary slides for the low-pressure cylinders. There is no comparison between the older and the newer gears, neither in the matter of simplicity nor of silence. For electric lighting work the merits of Corliss gear have been sadly over-rated; and in the haste to get a pretty indicator diagram many engineers have forgotten the complicated structure of these gears, and the consequent risk of an entire engine being thrown out by the derangement of one of countless little studs and pins. Under some conditions, not met with in electric light work, the Corliss gear will, no doubt, save steam; but we strongly suspect that not infrequently it saves it only to make a noise with it. The energy wasted in hubbub has not yet taken its place in a thermal balance-sheet; but if it were to do so, it would loom large in the statistics of some patterns of Corliss engine.

Judging from an article by Mr. Hermann S. Hering, in a recent number of the *Electrical World* of New York, the Americans have not yet given up entrusting the construction of their tramways and railways to the electrical engineer. "The civil engineering work of roadway construction is seldom designed and superintended by competent civil engineers," we are told. Our contemporary reflects that "in time electric railway engineers will probably have that part of civil engineering which relates to roadbeds included in their professional instruction." We sincerely hope that nothing of the sort will happen, at any rate, in this country. The proper person to set out curves and gradients, and to settle such matters as relate to foundations, cuttings, embankments, rails and their super-elevation, &c., is not the engineer who designs or superintends the manufacture of rolling stock. It was never so in steam railway work; where the functions of the civil and of the mechanical engineer have been always kept distinct. Why, then, adopt a polyphase system of duties for the electrical engineer when life is not long enough for him to learn his own work properly?

Mr. Hering passes on from the consideration of track construction to dilate upon other matters which affect the working expenses of an electric railway. He enlarges so ominously on the cost of stopping a car, and shows so convincingly how much would be saved if it were not stopped, that we can almost imagine a conference of managers debating the question: "Does it pay to stop our cars?" Another lamentable waste of money arises from the fact that when doing his "supper" trip—or the last trip at night—"the motorman will accelerate (use his controller on starting) as rapidly as possible, and these trips are always expensive to the Company." Turnouts also are wasteful, when they are too numerous; and this, we may add, is especially the case where frogs are used on the overhead trolley wire. We had occasion last week to describe a tramway blessed with no less than 27 turnouts in a length of six miles. A delay of but 60 seconds due to slowing down at each of these would add some 13 minutes to the time of a single run, and would necessitate the building of three additional motor cars to maintain a ten-minutes service.

Cable Interruptions and Repairs:—

	Date of Interruption.	Date of Repair.
Cadiz-Teneriffe	Sept. 25, 1895.	Nov. 22, 1895.
Perim-Assab	Nov. 19, 1895.	Nov. 26, 1895.

Electric Motors in Works.—The report of the Middlesbrough engineering firm of Dorman, Long and Co. (Limited) states that a saving of between £3,000 and £4,000 per annum is now being realised by the introduction of electric power for driving the outlying machinery.

Errata.—On page 110 of our issue of last week, under the heading of "Contemporary Electrical Science," there occurred two printer's errors. The seventh line from the bottom of the column should read: "gives the melting point of platinum as 1,780°C.," instead of "178°C.," as stated. On the sixth line read: "the cooling effect of air currents," instead of the "evolving" effect.

The Pollak Rectifier at Zurich.—The first application on a large scale of the Pollak system of charging accumulators by alternating currents (see *The Electrician*, August 9, 1895, Vol. XXXV., p. 488) has been made at Zurich in connection with the lighting of the new concert hall. The electric lighting of this building is carried out by 1,200 16 c.p. glow lamps and 50 large arc lamps. As the local supply station has nearly reached its full load in the evening, but has an available energy in the day time, a large battery of accumulators has been laid down in the building in question, which is charged during the day by the rectified alternating current from the mains.

Railway Carriage Lighting.—On Wednesday Messrs. J. Stone and Co., of Deptford, invited the Press to witness a trial run on the Tilbury and Southend Railway of a train fitted with their patented system of electric lighting. The train, consisting of an engine and tender, with two coaches, left Fenchurch-street at 5:5 p.m., and made a run as far as Grays, Essex, and back. In this system the dynamo is suspended under the frame of the carriage, and is driven by a belt off the carriage axle, the current obtained being used to charge a small accumulator. Provision is made for preventing the vibration of the carriage

Digitized by Google

axle being communicated to the dynamo, and, however much the speed of the train may vary, that of the dynamo is constantly uniform.

Horseless Carriages.—A meeting for the purpose of forming an Association in connection with self-propelled traffic is to be held on Tuesday, December 10th, at the Cannon-street Hotel, at three o'clock, at which Sir David Salomons, Bart., will preside. A series of resolutions will be proposed at the meeting, with the view to starting such an Association. As the trade may become an important one in England, it is hoped there will be a large attendance at the meeting. Tickets for the meeting may be had on application to Mr. Andrew W. Barr, 30, Moorgate-street, E.C., who is acting as honorary secretary for the time being. We may also remind our readers that Mr. W. Worby Beaumont is about to deliver a course of three Cantor lectures on "Mechanical Road Carriages." The first lecture of the course will be given on Monday evening next at eight o'clock, at the Society of Arts, John-street, Adelphi.

La Compagnie Française des Cables Télégraphiques.—This Company's Atlantic cable system, the breakdown of which was reported some time ago in *The Electrician*, is still interrupted, inasmuch as, after the "Faraday" had restored the Brest-Penzance section, and had finally recovered the Penzance-St. Pierre cable at the localised portion of the main break, which was found to be in upwards of 2,500 fathoms, another interruption was discovered some 200 miles further to the westward in 1,700 fathoms, and this was not touched. Moreover, the Brest-Penzance section again broke shortly after its restoration early in October last by the "Faraday," and is still interrupted, attempts made during the past few weeks to repair it with a small steamer having failed. The French cable-ship "François-Arago" has now returned from Madagascar, and it is rumoured that, the advanced season notwithstanding, the Compagnie Française propose chartering that vessel to proceed early next month to try and repair both of their cables.

Rapid Electric Tramway Construction.—Several American papers have lately published accounts describing the rapid construction of an electric tram line in Chicago. The road in question was about 1½ miles long. All the overhead material for the construction was in readiness before the equipment of the line was begun, and at 11·30 p.m. a gang of 300 men was set at work. In 22½ hours the work was completed and a car was running over the line. "There is no doubt that this was a remarkable performance," says the *Electric Railway Gazette* of New York, "but it is not as extraordinary as some of the papers have assumed. The equipment of the line from Weehawken to Fort Lee in New Jersey was a much more formidable undertaking, and under the circumstances the rapidity of construction was even more noteworthy." In this case about 100 men constructed over four miles of overhead line in six days, and it was even found necessary to blast rock before the majority of the poles could be set, while in Chicago the holes were dug in soft earth. It is to be hoped that the depreciation of this property will not be correspondingly rapid.

Use of Electricity on Railways.—Mr. J. R. Kendrick, third vice-president of the New York, New Haven and Hartford Railroad, referring to the proposed extension of electrical equipment on the Old Colony division, is reported to have said:—"We are entirely satisfied with our experiment on Nantasket beach business, the season having demonstrated the fact that the cheap and frequent trains create traffic. The passenger statistics for the summer just closed show an increase of 300 per cent. over those for the season 1894, and next year we expect these figures will be beaten. In regard to the report that our Company was taking steps looking to the equipment of the link between Nantasket junction and Braintree with electricity, I am at liberty to say that it is in every way correct. The plan that will be carried out provides for four tracks, the two outer for trolley cars and the inner for steam. The centre tracks will be fenced in so that there will be no possibility of injury to passengers when using the electric cars."

American Street Railway Finance.—At the recent annual meeting in New York of the American Society of Railroad Superintendents, Col. H. G. Prout, editor of the *Railroad Gazette*, delivered a lengthy address on "The Use of Electricity as a Motive Power on Railroads Now Operated by Steam." In the course of this address the following noteworthy passage occurred: "There is, however, a set of conditions at work which will change the situation of the present electric railroads a good deal before long. Up to the present time it has been, and still is, easy to finance them, because rail mills and electrical manufacturers are glad to help float the bonds of new electric railroad projects; the public is credulous and investors look for great profits. We are, therefore, in the midst of the 'kiting' epoch of electric railroads, when bonds which are sold to-day pay the interest on the bonds sold last month or last year. But, naturally, this situation must come to an end before long." Once more we repeat the hope that we shall not import into this country America's financial methods along with its admirable electrical devices.

British Association Speakers.—An American, who attended the recent meeting of the British Association at Ipswich, has been criticising the style of speaking current at these gatherings. He says that among the leaders of the various sections of the Association there are few good speakers, and he could not help contrasting the oratory, as he passed from room to room, with that which he had heard only a fortnight before at the Trades Union Congress at Cardiff. The labour leaders, he remarks' know nothing about science, but they understand the art of speaking without hesitation and circumlocution, and know how to hit the mark. The educated professors, with few exceptions, do not speak well. "They have a halting, hesitating manner, are constantly 'hemming' and 'hawing' and changing the construction of their sentences. An accurate phonetic transcription of speeches delivered at this session would be a curious and amusing study. It would be punctuated with sighs, ejaculations and groans, and would be a veritable maze of mixed constructions and circumlocution. There are some excellent speakers among the regular attendants at section work, but the majority of them are careless and slovenly talkers to whom it is almost painful to listen."

The Fastnet Lighthouse Cable.—We are requested to state that the paragraph which has recently appeared in many of the daily papers relating to the breaking of the Fastnet lighthouse and Crookhaven cable is somewhat misleading. The communication is effected by means of the non-continuous cable system, first suggested by the late Mr. Willoughby Smith, and has worked satisfactorily for over four months. The system necessitates two short lengths of strong bare copper cable being bolted to the rock from the lighthouse to the water's edge, and this can only be done when the sea is exceptionally smooth—a very rare thing at the Fastnet. Owing, however, to the persistent bad weather, the cable down the north face of the rock could not be absolutely secured, and has, therefore, given way. Communication can be, and has been, maintained, except in the very roughest weather, by means of a temporary copper wire which the lighthouse men throw over the side of the rock so that the end just enters the water. The main cable, about nine miles long, which terminates at a mushroom submerged in the vicinity of the rock at a depth of about 80ft., still remains in perfect order.

Ships' Side-Lights.—The *Shipping Gazette and Lloyd's List* publishes the substance of the report of the departmental committee appointed by the Board of Trade to inquire into the subject of the screening of ships' side-lights. The Order in Council of January 30, 1893, professed to secure compliance with the international regulations affecting the screening of side-lights by providing that the rays from the red and green lights must be screened to an angle of four degrees from the outside edge of the wick. The position taken up by the shipping interest was that this requirement constituted a serious danger to navigation, and was calculated to increase rather than diminish the risk of collision. The Committee conclude their report in the following terms:—"(1) That the Order in Council of January 30, 1893, be cancelled. (2) That in the case of oil lamps the forward edge of the screen or chock on it should be in a line parallel to the keel with the inside edge of

Digitized by Google

the wick. (3) That in the case of electric lights there should be a similar screening in regard to the inside edge of the filament. (4) That the breadth of the wick of oil lamps, and of the filaments in the case of the electric light, should be not more than 2in. nor less than 1in., measured at right angles to the fore and aft line of the ship. (5) That the visibility of the green light should as nearly as possible be equalised to that of the red by the employment of higher candle-power, and that the mast-head light should not be so powerful as to diminish the visibility of the side-lights."

The "Belt Line" Tunnel Electric Locomotive.—The 96-ton electric locomotive has now been in operation on the Belt Line of the Baltimore and Ohio Railway since August 4th last, and according to the American Electrical Journals has been hauling the entire north bound freight service of that railway. Some tests have been made of its capabilities, and in the following we give a few of the more important data. A train consisting of 27 loaded freight cars and two steam locomotives, not working, of a total weight of 1,125 tons, was hauled up a gradien of 42ft. to a mile. At the end of one minute the train was moving at a speed of 10½ miles an hour, and at this point the speed was increased to the usual rate. The distance moved in 40 seconds was 150ft., and in one minute 450ft. Another test was made with a dynamometer car placed between the electric locomotive and the train, which consisted of 22 cars loaded with coal, one guard's brake and two locomotives. The total weight was 1,068 tons. On the 10 per cent. grade in the tunnel an average drawbar pull of some 25,000lb. was obtained from the dynamometer diagram. The speed at this point was 11⅛ miles per hour. A test with a train of 1,600 tons weight showed a drawbar pull of 45,000lb. On October 6th a train over 1,800ft. long and weighing about 1,900 tons was started from rest in the tunnel. It consisted of a north bound freight train of 28 loaded cars and two locomotives coupled to a local freight of 15 loaded cars and one locomotive. The maximum drawbar pull in this instance was 60,000lb., and a speed of 12 miles an hour was obtained.

Light Railways Association.—A meeting of gentlemen interested in the encouragement and construction of light railways in Great Britain was held on Wednesday last at 17, Victoria-street. The meeting was convened to consider (1) what steps should be taken to amend the laws at present governing such enterprises; (2) to appoint a deputation to wait upon the President of the Board of Trade to formulate the views of the Conference; (3) to establish an association to support and foster the movement; and (4) generally to take all such steps as may be considered desirable in connection therewith. Among those present were Gen. Hutchinson, Major-Gen. Webber, Mr. J. G. B. Elliot (Secretary of the Tramways Institute), Mr. W. M. Acworth, Mr. W. J. Carruthers Wain. Mr. Carruthers Wain was voted to the chair. The Chairman suggested that a strong committee should be formed—a council of administration—to be guided by the advice of experienced engineers and solicitors; and with their aid the association might be able to formulate suggestions, or a scheme, which might be useful to the new President of the Board of Trade when he came to submit his proposals to Parliament. The following committee was nominated:—Gen. Hutchinson, Major-Gen. Webber, Mr. A. C. Payne, Major Rasch, M.P., Sir Douglas Fox, Mr. Hamilton Smythe, Mr. W. J. Carruthers Wain, Mr. R. Harding Milward, the Duke of Sutherland, Lord Wantage, Mr. Beachcroft (of the London County Council), Dr. Carte and Mr. W. M. Murphy (of Dublin), with power to add to their number.

Portland (Oregon) Electric Transmission Plant.—American electrical papers of recent date contain descriptions of a 12-mile electric transmission plant at Portland, part of which has been in operation for some time, the current being employed for lighting, power, and traction purposes. As motive power the falls of the Willametta river, near Oregon city, are used. The power house is situated alongside a head-water canal, and consists of 20 sections, 5 of which are already built, and the remainder are in course of construction. The fall is 40ft., with an estimated total capacity of 50,000 H.P. The ultimate generating capacity of the station, however, will be only 12,800 H.P. At present there are three units, each consisting of a pair of vertical Victor turbine wheels 42in. and 60in. in diameter respectively, and a 450-kilowatt generator coupled direct to the shaft of the smaller. The larger wheel is an auxiliary, to be brought into service only at periods of excessive high water, which the records show occur about once in every five years. The smaller wheel runs at a speed of 200 revolutions per minute, and the larger at 100 revolutions per minute. Both turbines are set at the same level, and each carries a pulley. When the large wheel is in operation, the two pulleys are belted together, the smaller wheel is disconnected, and the large wheel drives the generator at a uniform speed of 200 revolutions. When the smaller turbine is operated alone, the belt lies upon a shelf surrounding the pulleys. The generators are of the three-phase type, with a frequency of 33 cycles per second, and an E.M.F. of 6,000 volts. Two exciters of 250 kilowatts each are provided. Each of these machines is capable of exciting the whole 20 generators which it is proposed to ultimately put down. At present one of the exciters is used for supplying current to the electric tramways at Oregon city. From the generators the current is carried to Portland by overhead conductors, a separate circuit being installed for each machine. At the sub-station the current is transformed. Forty-five transformers are at present in use, of which 15 are connected to each generator, five being placed between each pair of wires of the three-phase system. The distribution of light from the secondaries is effected on the Edison four-wire system. The direct current for the railway service is obtained by conversion from the three-phase alternating current. This is effected by means of rotary transformers, two of which are at present installed in the sub-station, each having a capacity of 500 H.P. The long-distance transmission lines for this railway service as in the case of the lightning circuits, are connected to step-down transformers, transforming the current from 6,000 volts on the line to 400 volts at the secondaries. The secondaries are connected to the three collector rings of the rotary converter. The alternating current at 400 volts is then converted into direct current at 500 volts at no load, and 550 volts at full load.

Contemporary Electrical Science.—An accurate method of measuring specific inductive capacities is described by H. Pellat in the November *Journal de Physique*. It is founded upon the increase of attraction between the armatures of a charged condenser on replacing the air between them by the dielectric under investigation. The way this is managed is by an attracted disc electrometer with two discs attached to the top and bottom of a vertical rod, and suspended by one arm of a balance between two attracting discs above and below. The attracted discs are surrounded by stationary guard rings. After equilibrium is established, a slab or layer of the dielectric is placed upon the upper guard ring, and the upper attracting disc is shifted until equilibrium is once more established. This point is determined by observing through a telescope the motion of the rod carrying the attracted discs. This method can be carried to a point of extreme accuracy, and the practical limit only lies in the measurement of the thickness of the dielectric. Liquids can be dealt with in the same way, by putting them into flat dishes, or they may be introduced between the lower pair of discs in contact with the metal itself.—Wladimir de Nikolaieve introduces us to the somewhat unfamiliar phenomena of magnetic self-induction, by a discussion of the cause of the repulsion of Elihu Thomson's ring. "A piece of iron," he says, "attached to the end of the core of an electro-magnet, will drop off if a disc of copper is moved along the core. An increase of the magnetising current is observed at the same time. This diminution of the attraction of the iron is due to magnetic self-induction." If there are magnetic (displacement) currents, why not magnetic self-induction?—E. von Aubel and R. Paillot scrutinise the validity of the law enunciated by Wiedemann and Franz, that metals of fairly good thermal conductivity have an electrical conductivity varying in proportion. Taking the case of aluminium bronze, "constantane" and ferro-nickel—all alloys of high electrical resistance—they find that this law is anything but verified, although a rough kind of correspondence may be observed. The law evidently holds for pure metals only of homogeneous structure.

MOTIVE POWER AND GEARING.*

(*Continued from page 7*).

BY E. TREMLETT CARTER.

Water-jacket Heat.—Undoubtedly the exigencies of construction make the chiefest inroads upon the heat account, and cause large amounts of energy to be thrown away. Were it not that, at all costs, the working parts of the gas engine must be kept from growing red hot, or even approaching the temperature of free explosion, we might have a much more economical gas motor. No doubt whatever this difficulty will in time be overcome; and, instead of the materials we now use, we shall make our explosion chambers, and the working parts which are directly exposed to the hot gas, of some more highly refractory materials. It will, perhaps, scarcely be credited that in an "Otto" cycle gas engine of modern construction it is quite usual for *more than 50 per cent.* of the total energy of the gas to be passed into the water jacket.

One of the partial remedies for this great waste of heat has already been referred to—viz., an increase in the piston speed. It needs no saying that to this remedy there is a limitation which is soon reached; indeed, with the highest speeds found to be practicable at the present time the jacket losses are rarely, if ever, lower than 40 per cent. A high piston speed was advocated even by de Rochas, who perceived the supreme necessity for getting useful effect from the gas before it had time to give up its heat to the surrounding metal.

A slowly-moving piston is a fatal mistake, because it permits the gases to remain long in contact with the water-cooled walls of the cylinder.

It may here be remarked that Dr. Witz has shown experimentally that an increase in the piston speed causes a corresponding increase in the rapidity of the explosion, the maximum pressure of the gas and the completion of the combustion taking place earlier when the piston speed is raised.

Ignition Gas.—It is not customary to include the volume of gas used in maintaining an ignition flame, or in heating an ignition tube, in any estimate of the performance of a gas engine. From the nature of the case, it is clear that this volume of gas is very nearly independent of the size or power of the engine. Ignition tubes are now almost universally employed, and the gas required to keep one of these properly heated is about 4 cubic ft. to 10 cubic ft. per hour. The gas is usually burned in a Bunsen type of burner. At the Belfast electric supply station the ignition gas for the engines is being specially metered.

Incomplete Combustion.—Strictly speaking, loss due to the escape of unburnt or partially burnt gas is not directly loss of heat, but of the potential energy of the substance from which heat might have been obtained. It has already been stated that the whole of the gaseous fuel admitted in one charge does not become burned by the time of the maximum pressure and temperature of the gases, but that a considerable part of it liberates its heat at a later period, when the pressure and temperature are falling. This phenomenon is called *after burning*; and when it is carried beyond the moment when exhaust commences, loss by incomplete combustion may be said to result. That this after burning really takes place, a careful examination of the indicator diagram of a gas engine will show.

To make this clear, however, it is necessary to mention a restriction of the combined law of Boyle and Charles, which correlates pressure, volume and temperature. *That law is not necessarily true if chemical change goes on within the gas.* For example, it is not true for a mixture of hydrogen and oxygen at temperatures at which the fired gases would condense into water. There is, then, no *a priori* necessity that the P.V. law of the gaseous charge fired in a cylinder shall remain unchanged throughout the working stroke. As a matter of fact, however, experimental data warrant the conclusion that, at the high temperatures found in a gas engine cylinder, the products of perfect and of imperfect combustion have the same P.V. law as the explosive mixture of gas and air. In analysing the indicator diagram, therefore, we may ignore altogether the chemical changes which have been going on in the cylinder, and may treat the working substance as if it were a stable gas.

Proceeding upon this datum, if we compare the actual line of working pressure throughout the working stroke, with the adiabatic line drawn through the point of maximum pressure, we discover one or another of the following surprising results: (1) The two lines will be almost identical; or, (2) the working line will actually rise above the adiabatic line; or, (3) the difference between them will be smaller than is necessary to account for the great abstraction of heat by the water jacket. All these three relations are met with in gas-engine practice, in general. Now, it is evident from any one of these results, but most forcibly from the second of them, that during the process of expansion the gas has been receiving heat from some source. The heat represented by the state of the gas at its maximum pressure is not sufficient in amount to account for the behaviour of the gas. The only admissible inference is that combustion has been going on at a later stage than the point of maximum pressure. We may carry the investigation further, and determine the rate of combustion at each part of the stroke, obtaining a curve showing the extended combustion of the entire charge. But for this investigation the reader is referred to a more ample treatise on the subject.

It has been found that the percentage of after burning, and therefore the liability to loss from incomplete combustion, increases as the percentage of gaseous fuel in the charge is diminished. The loss by the rejection of unburnt gas into the exhaust is therefore more likely to arise when an engine is working on a small fraction of full load.

Engines Worked on the Otto Cycle.

Before passing to the study of one or two complete examples of gas engines working on the Otto cycle, we will consider the structure and action of some of the details of these engines. It will be as well to state at the outset that none of these details have any logical connection with this cycle. Any one of them might be used in engines working on other cycles; or it might be replaced in an Otto-cycle engine by another kind of mechanism. The details have been chosen with a view to represent the best or the most common modern practice in Otto-cycle engines.

Ignition Apparatus.—Various devices for igniting the explosive mixture in a gas engine have been adopted, but these all have by now become almost obsolete, with the exception of the hot tube. Electric spark ignition has two principal defects: the deterioration of the spark electrodes inside the cylinder, owing to the high temperature; and the complications due to the use of induction coils or other spark-producing apparatus. Flame ignition, by means of sliding valves, was for long in use; and its disappearance came about, not so much because the flame ignition itself was defective as for the reason that slide valves had to be abandoned. The admission and exhaust of the gases exclusively through lift valves, which is now general practice, rendered flame ignition practically impossible. The hot-tube method of igniting was first introduced in 1879, by Mr. Atkinson. In its simplest form it consists of a short stout tube of wrought iron, steel or porcelain, with its lower end in communication with the back of the cylinder and its upper end sealed in some suitable manner. This tube is maintained at a bright red heat—sufficient to ignite the compressed gases—by means of a Bunsen flame applied to it externally. When unprovided with a timing valve, the ignition tube is always in communication with the back of the cylinder; and explosion is determined by the fact that the mixed gases will not ignite until a certain degree of compression has taken place. The compression stroke of the engine forces some of the explosive charge into the hot tube, and at a certain point ignition results. When thus used, the ignition tube is liable to be uncertain in its action; and for all but very small engines it is now commonly provided with a timing valve, by which the communication with the cylinder is not opened until the proper

Digitized by Google

moment for explosion to take place. Fig. 75 shows in section one arrangement of hot tube and timing valve used in the "Robey" gas engine. The flame of the Bunsen burner, A, heats the tube, E, which is fitted inside the chimney, F. The lower end of this tube communicates, through the timing valve, D, with the ignition port, B. The

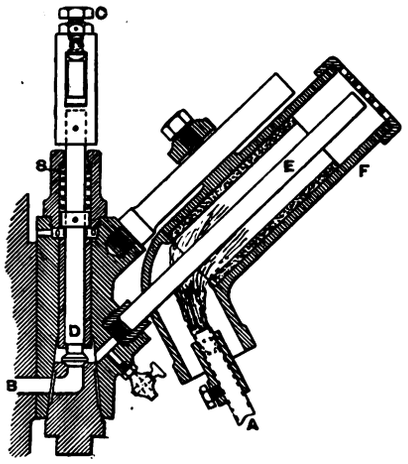

Fig. 75.—"Robey" Ignition Tube and Timing Valve; Early Form.

timing valve is lifted by a rod which slides insides a sleeve, and which is normally held down by the spring, S. The lifting is effected by a lever, actuated by a cam on the valve shaft of the engine; and this lever presses upward against the stud, C, which may be adjusted within small limits. These adjustments will determine the instant of explosion. A later form of the apparatus is shown in Fig. 76.

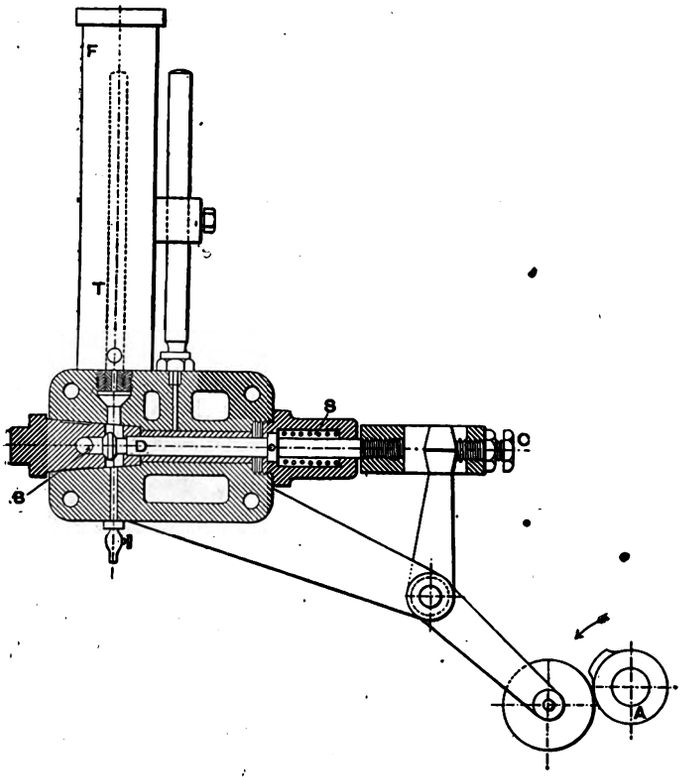

Fig. 76.—"Robey" Ignition Tube and Timing Valve; Later Form.

The chief defect in a properly constructed hot-tube ignition apparatus is the rapid deterioration of the tube, whereby it becomes necessary frequently to renew the tube in order that the engine may not break down through the tube bursting. The longest life of a good wrought-iron tube is not much in excess of 100 hours; and it is more common to have to renew the tube after from 50 to 60 hours. A six-inch length of wrought-iron steam pipe, of ½in. bore, well plugged at one end, makes as serviceable and cheap an ignition tube as the author knows. This will generally last about 50 hours, and the cost does not exceed 1·5 pence. The longest life of tube the author has met with has been in very short porcelain tubes, but these are more expensive initially than those of wrought iron.

Governors and Governing Gear.—Gas engine governing may be classified under two heads: (1) Governing by miss-fire, or the omission of explosions; and (2) governing by a graduation of the explosive force, generally by varying the amount of gas admitted in each charging stroke, but sometimes by variation both of the amount of air and of gas. In some engines these two methods are combined, the graded charges regulating the speed down to a certain fraction of full load, below which explosions are missed.

Miss-fire Governors.—There are many objections to the omission of explosions for one or more cycles; but this method of governing has the advantage of simplicity and convenience, besides that under great variations of load it is more economical than the graduation of the charge. Its main objections are: (1) That it tends to unsteadiness of speed; (2) that it is not sufficiently fine for small variations of load; and (3) that consequently a heavier flywheel is required, with the attendant increase in the weight and friction of the engine. It tends to unsteadiness of speed, because, although the

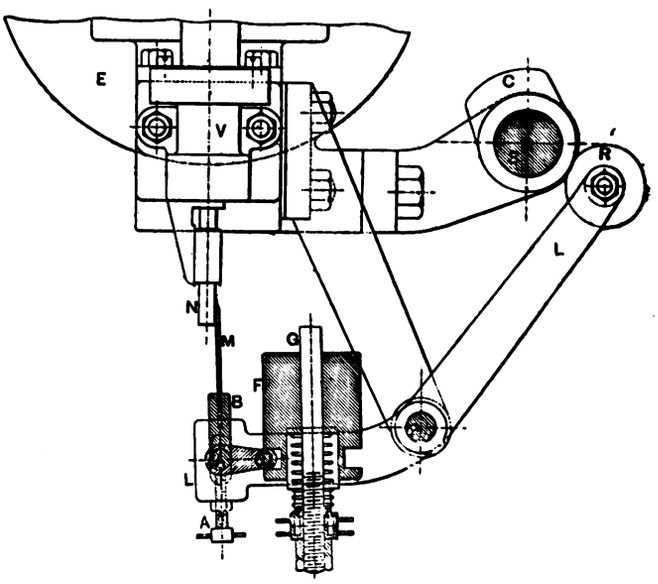

Fig. 77.—Vibrating Governor of "Stockport" Gas Engine.

omission of an explosion may seem theoretically simple, as a matter of fact almost all, if not quite all, governors will miss two or three explosions in succession, where only one omission is required; and then will allow a rapid succession of explosions, where one or more should have been omitted. It also tends to unsteadiness, for the reason that after the omission of one or more of the explosions the cylinder is free of waste gases, and the next explosion will therefore be exceptionally violent, through the excessive richness of the charge. The heavy flywheel is partially a necessary consequence of a cycle which involves an idle revolution and a-half; but it is all the more necessary when, by the omission of an entire cycle of activity, the task of doing work for three and a-half revolutions or more is wholly thrown on the flywheel.

Fig. 77 shows the form of miss-fire governor used in the "Stockport" engines. The gas admission valve, V, is lifted by the spindle, N. A cam, C, on the valve shaft, S, when it presses on the roller, R, causes the lever, L, to be depressed in its right-hand part and lifted in its left-hand part, this lever moving about the pivot, P. Upon the extreme left-hand part of this lever there is carried a bell-crank lever, B, which has at one end a pin, D, and at the other end a lifting rod, M, the upper end of which rod is bevelled down to a sharp edge. The bell-crank lever can be turned about the pivot, A, by the action of a collar, F, carried on a rod, G, which is raised or

Digitized by Google

lowered by the centrifugal governor. It will be seen that when M is shifted so as to fall just underneath N, as M rises and falls with the motion of the lever, L, its rise will cause the valve, V, on the cylinder end, E, to be opened, and gas will be admitted. Whereas, when the governor lifts with rise of speed, the rod, G, will be depressed, and M will be forced aside; with the result that M will miss the valve spindle, N, and will rise beside of it, causing the omission of an explosion, by preventing the entry of gas. The governor used in the "Robey" gas engine is shown in Fig. 78. In this, a

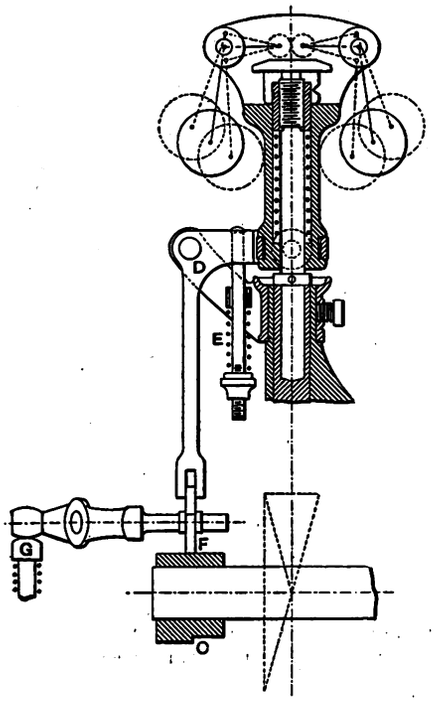

FIG. 78.—"Robey" Gas Engine Governor.

"Richardson" governor actuates a lever, D, on the lower end of which a roller, F, is carried. By the play of the governor this roller will be shifted to the right, on to the cam, C, when it will actuate the gas valve, G; or else it will be shifted to the left, leaving the cam and causing the omission of gas supply. An adjusting screw, E, enables the speed to be regulated, by supplementing the controlling force on the governor.

(To be continued.)

A 1,000-UNIT FLYWHEEL ALTERNATOR.

The latest addition to the generating plant at the Deptford station of the London Electric Supply Corporation is a 1,000-unit flywheel alternator, direct coupled to a 1,500 H.P. compound triple-crank steam engine. The alternator is by Messrs. S. Z. de Ferranti and Co., and the steam engine—or engines, for there are really three engines on one crank shaft—by Messrs. Plenty and Sons. Through the courtesy of Mr. P. W. d'Alton, the chief engineer to the London Electric Supply Corporation, we are able to publish two illustrations and some particulars of this interesting and imposing piece of engineering, which, we may say at the outset, reflects the highest credit upon all who have been concerned in its design and manufacture.

Nominally rated at 1,000 kilowatts, the alternator will usually develop 100 amperes at 10,700 volts, allowing for the 700 volts drop in the transmission system; and it is capable of giving continuously a very much larger output if called upon to do so. The radial-field type, adopted by Mr. Ferranti in his Portsmouth alternators, has not here been followed; a return having been made to the parallel-field type of his earlier machines, on account of the higher frequency at Deptford. The armature coils, 64 in number, are mounted in pairs on ebonite-insulated spokes projecting from the rim of the flywheel. The coils are thus carried between two circles of field-magnet coils, 64 of these latter coils being placed on one side and an equal number on the other side; and all the field coils being mounted upon the inside of the cast-iron circular frame (upon which, in Fig. 1, is the name plate). The armature complete weighs 35 tons, and its extreme diameter is 22ft.; the diameter of the pitch circle of the coils is 20ft. The speed at all loads is 156 revolutions per minute; and as this involves a linear velocity of 10,800ft. per minute, it will be seen that the centrifugal stresses against which the copper coils have had to be designed are something enormous. The armature coils are wound with hard-drawn copper ribbon, $\frac{3}{4}$in. wide, upon a core of laminated brass insulated with asbestos. The windings, both of the armature and of the field coils, are bare. The current density in the armature does not exceed 2,000 amperes per square inch, at full load; and in the field coils it does not exceed half that figure. The field coils are wound on solid cores of hammered scrap wrought iron, the cores being of circular section, 5in. in diameter, in the main part, and fitted with a pole-piece shaped in a rectangle with rounded ends, of 9in. diameter across the circular ends. Over the pole face a 9in. circular cap of insulating material is securely fixed, the purpose of this being to prevent sparking from the armature to the field coils or cores. Some hard experience had to be gone through before the right sort of material for these caps could be found, as it is no easy matter to prevent sparking at 10,700 volts through a mere $\frac{1}{8}$in. or $\frac{5}{32}$in. of material. Woodite was tried, and while some caps of this material could stand over 20,000 volts, others broke down rapidly under normal pressure. The present caps are of enamelled micanite, $\frac{5}{32}$in. in thickness. Into the gaps between the rectangular pole-piece and the circular cap, gunmetal filling pieces have been bolted. The clearance between any pole and the opposite pole on the other side of the armature is, when the machine is running, $1\frac{3}{4}$in.; and this is composed of $\frac{3}{4}$in. for the armature, $\frac{5}{16}$in. for the two insulating micanite caps, and $\frac{1}{32}$in. for each air clearance between the armature and the pole caps. So narrow an air gap necessitates that the armature coils should be securely mounted, and that some means of adjustment should be provided for bringing them into exact centre. These provisions are made in the following manner: Each pair of armature coils is first held in position in a frame and placed between two heavy bronze castings, with a sheet of mica between each casting and the metal of the coils. The castings are then hydraulically squeezed towards one another, so as to grip the coils tightly; and while in this position the castings are riveted together. The solidly-built armature pair is now mounted upon a pair of radial pillars or spokes projecting outwards from the rim of the flywheel. These pillars are arranged in pairs, side by side, and the bronze holder of the armature coils is bolted between the pillars in such a way that by the adjustment of a locked nut on the end of each pillar the coils may be shifted laterally and thereby be brought into exact centre. The nuts on the pillars are ebonite insulated.

The rim of the flywheel which carries the armature coils is in two parts, held together at the rim by two steel rings shrunk over lugs or bosses on the inner side. Each ring is 23in. in diameter and 5in. by 3in. in cross-section, and is of Siemens-Martin forged steel. The rim is also held by eight double spokes of rectangular section and eight mild steel tie rods. These ties are of $5\frac{1}{2}$in. diameter in the body, and have 6in. screws at their ends. At their inner ends they are secured to a mild steel block shrunk on to the armature spindle. This spindle is 18in. in diameter in the main portion, coned to 12in. in the bearings, and it is flange coupled to the end of the engine shaft. The bearings are each 3ft. long, and are of the spherical pattern admired by Mr. Ferranti. A collar on the shaft outside each bearing serves to prevent end motion. We should mention that the frame of the field magnets is in two separate portions, one on each side of the armature; and that by means of an electrically-driven worm gear these two halves may be drawn apart some 20in., for cleaning or repairs. They had been partially opened out when the photograph, Fig. 2, was taken.

Several electrical and mechanical conditions have had to be complied with in the construction of this alternator. The rim

Digitized by Google

of the flywheel has been made strong enough to hold itself together if it could be run up to speed without any other support than its own material and the rings at its joints; its arms are strong enough to hold the wheel intact, if it could be run with the rim fractured between each adjacent pair of arms; and the same strength has been given to the tie rods, they being strong enough to hold the rim should the arms be fractured. The chief electrical conditions were that the electrical efficiency of the alternator should not be less than 97 per cent.; that the current density in the armature and field coils should not exceed 2,000 and 1,000 amperes per square inch respectively; that the C^2R loss in the armature should not be more than 0·8

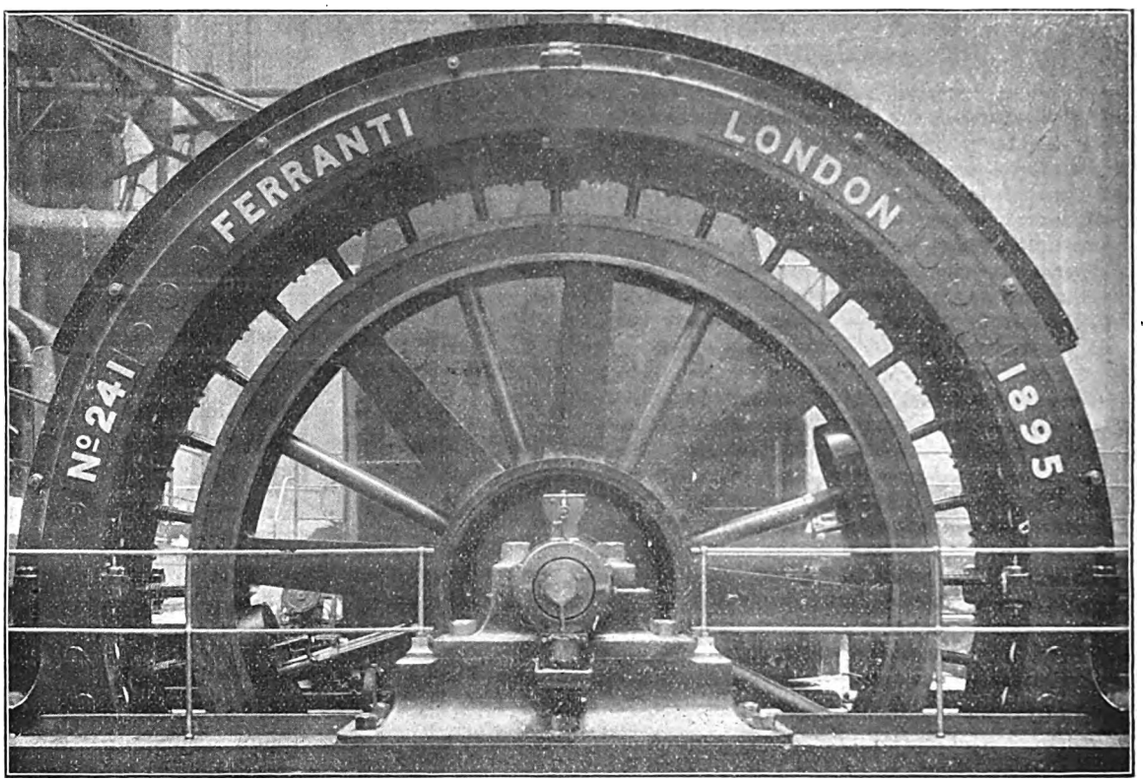

FIG. 1.—1,000-unit Flywheel Alternator at Deptford.

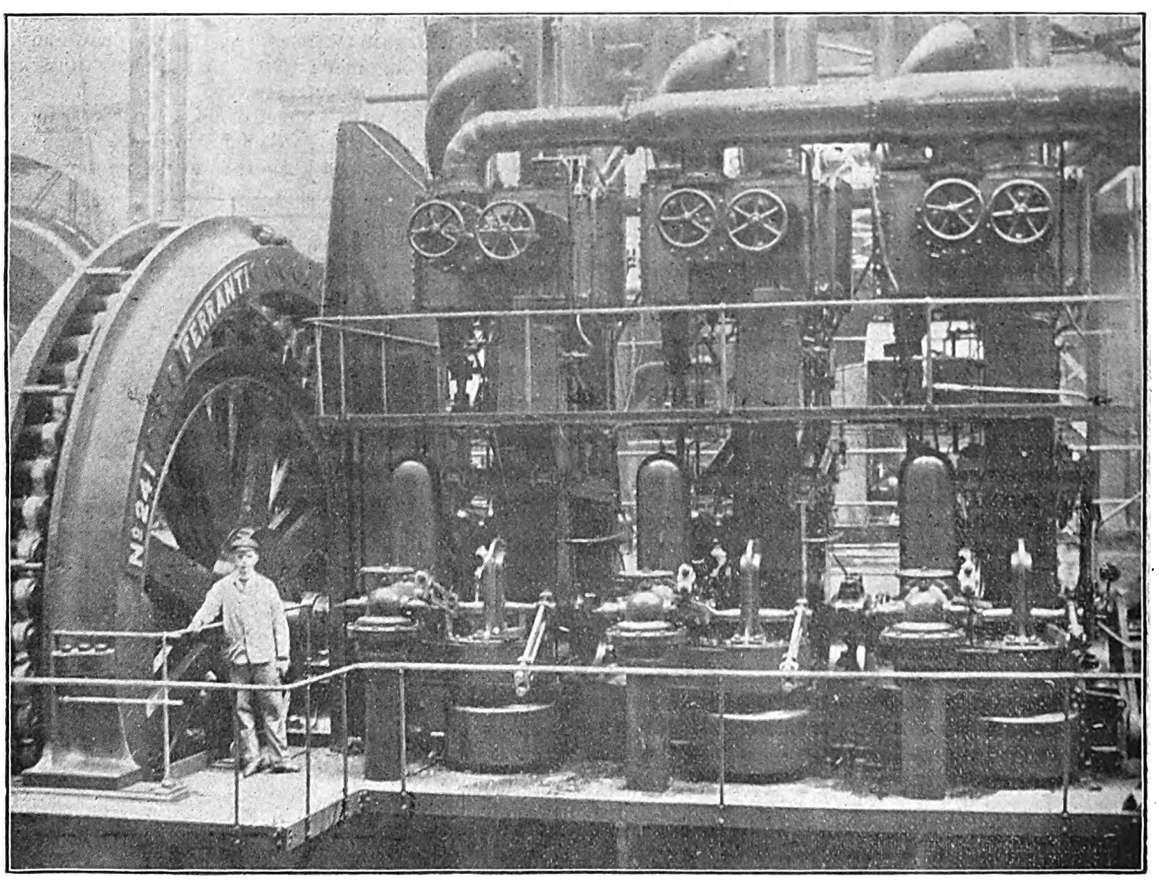

FIG. 2.—1,500-H.P. Steam Engine coupled to Flywheel Alternator at Deptford.

Digitized by Google

per cent. of the output; and that the excitation should not be more than 2 per cent. of the output. As a matter of fact, the excitation is well within the limit, being 300 amperes at 50 volts.

Turning now to the engine, a view of which, with a portion of the alternator, is shown in Fig. 2: this is in reality three separate tandem compound engines driving three cranks on the same shaft. The three sections of the crank shaft are interchangeable, as are all similar parts of all three engines; so that the breakdown of any one engine need not long stop the set, as the other two can be run by themselves, the only delay being that necessitated by the disconnection of the damaged engine or the interchange of a broken crank section and a good one. Each engine is built to develop 500 I.H.P. with steam at 140lb. on the engine side of the stop valve, and running at 156 revolutions per minute. The steam pressure at Deptford is often 180lb., so there is ample reserve of power, and it is estimated that 2,000 I.H.P. will be available from the three engines. The stroke is 26in., and the diameters of the high and low-pressure cylinders are 17½in. and 36in. respectively. The steam is distributed to the high-pressure cylinder by piston valves, and to the low-pressure cylinder by a D-slide valve, all these valves having the same travel, and being carried by the same valve rod and eccentric gear. The weight of the valve gear is supported by the pressure of live steam on a piston in a small cylinder on the top of valve chest; and in the down travel steam acts on the top of this piston. Variation of cut-off in both cylinders is effected by varying the travel of the valves, which in turn is controlled by Joy's hydraulic valve gear. The action of this expansion gear consists in hydraulically shifting the position of the eccentric with respect to the shaft, the throw of the eccentric being varied between zero, or in-centre—when the cut-off would be close to the commencement of the stroke—and the full half-travel, when the latest cut-off of about five-eighth stroke would take place. The eccentric is continually pressed in-centrewards by means of steel springs, and outwards by means of water pumped through a 1in. hole passing through the crank shaft. The hydraulic pressure, and therefore the position of the eccentric, is regulated by means of a small centrifugal governor.

Each engine is provided with a separate jet condenser and air pump. The condensers are formed inside the back cast-iron columns which support the engines (these columns are seen in Fig. 2), and the air pumps are situated at the bases of the columns. Inside the condenser chamber the steam is indrawn from the top and meets the injection water, which is sprayed upwards from a nozzle at the bottom. Water from the adjacent Thames is used for injection, this water being carried into the condenser by the vacuum, and without an injection pump. The tank is filled by the river every high tide, and contains more than enough water to condense all the steam used in the station between tides. The ejection from the air pumps is conveyed direct to the river, only a small portion being returned to the reservoir at times when the water in the latter is liable to freeze. Occasionally, however, the particular engine set under consideration is run non-condensing, when the pump rods are disconnected from the beams, as shown in Fig. 2.

The Third Rail Patent in the United States.—"Answers have been filed," says the *Street Railway Review* of Chicago, "in the cases of Siemens and Halske Electric Company *v.* The Metropolitan West Side Elevated Railroad for infringement of third rail patents issued in July and August, 1885, to Ernest Werner Siemens, Nos. 322,859 and 324,176. The case is defended by the General Electric Company, and the answers were filed by defendants November 4th. They enumerate several hundred United States and foreign patents which were issued previous to those of Siemens, and which, it is claimed, cover the same grounds. The answer further claims that the use of the third rail was well known and had been applied in the art prior to the issuance of the patents to Siemens in 1885. As proof of this are cited numerous articles in the technical Press, and especially a Paper read before the Society of Arts by Alexander Siemens and Edward Hopkinson on the 'Portrush (Ireland) Electric Railway,' in April, 1883."

THE DESTRUCTION OF THE CROMPTON WORKS.

On Friday morning last a fire occurred at Messrs. Crompton and Co.'s works at Chelmsford, which resulted in the destruction of the greater portion of the premises. The Arc Works were of a somewhat peculiar nature, comprising, as they did, not only a manufacturing concern, but also a generating station of no mean order. This station, which was packed in between the shops, was the primary cause of the disaster.

One side of the station was open to a large erecting shop, and was separated by a wall from the tool shop on the south. On the east a main gangway through the works separated the engine room from the chief machine and fitting shops, above which were the armature shops. On the west a wall divides the station entirely from the portion of the works on that side. Adjoining is an erecting shop, over which is a large pattern stores. Beyond this are the lamp and switch shops. Above the engine room and tool shop were the copper and general stores respectively, and again above were the drawing and general offices. The dynamo stores adjoin the lamp shop. The lighting plant consisted of three Crompton-Brunton alternators of 80, 50 and 35 kilowatts respectively, and one Mordey-Victoria alternator of 100 kilowatts, and also three Crompton continuous-current generators. These machines were driven by four Willans engines, having a total indicated horse-power of 410, and were responsible for the lighting of the town of Chelmsford, both public and private, and for the driving of the shop motors in the works. A new main alternator switchboard had recently been erected in the engine room, near to but quite apart from the distributing board.

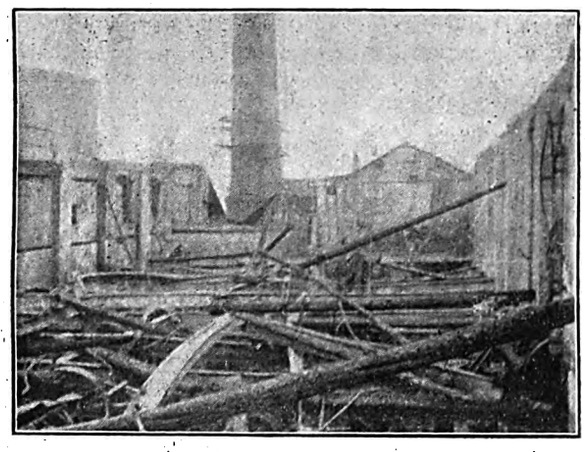
The outbreak occurred at about twenty minutes to nine, when most of the workmen were away at breakfast. An engine driver was sitting in front of the main board eating his own breakfast, when, smelling something burning, he hastily turned round and saw that the back of the board was on fire. He at once ran for a fire bucket, at the same time calling out for assistance. On returning, however, the smoke was so dense that he was unable to get near the flames, which had risen to the wooden rafters above. The men in the works at the time had got out the works hose, but within two or three minutes were driven away from the fire by the volumes of smoke. The continual blowing of the steam horn which summons the workmen after meals soon brought the staff and workmen to the scene; but nothing that was done could check the tremendous rush of the flames in all directions. In ten minutes the inside of the engine room was one roaring furnace, and the flames were shooting up into the air and licking the side walls of the stores, and above that of the drawing office. At half-past nine the whole block of buildings above and around the unfortunate generating plant was in flames—tool shop, general stores, copper stores, and general and drawing offices, also the machine shops, fitting shops and armature shops. The heavy wooden floors soaked with oil from the machinery burned furiously, and crash after crash resounded as one machine after another fell from above. At half-past ten roofs and floors had all gone through, and the fire brigade had difficulty in getting near enough to play well into the fire because of the great heat.

Among the first on the scene were Mr. S. L. Brunton, the works manager, and Mr. J. W. Rook, the head of the clerical staff, and very hard did these gentlemen, together with Mr. George Mason, Mr. W. P. Whitehead and others, work. Mr. J. P. Nelson, of the power department, Mr. E. A. N. Pochin, and Mr. H. J. Fereday were among the most active members of the staff. Mr. Crompton, who had been summoned from London, was unable to get down till about half-past eleven, by which time the place was entirely gutted. He was accompanied by Mr. W. A. Chamen, of the engineers' department. Mr. H. C. Hawkins was also hastily summoned from London. Fortunately the wind was calm, otherwise not a portion of the works could have been saved. By one o'clock the fire had almost burnt itself out, but all through the day several jets of water were playing on the smoking ruins. During the night the firemen were kept constantly at work,

Digitized by Google

and they continued at work all through Saturday. On Tuesday portions of the wreckage were still smoking.

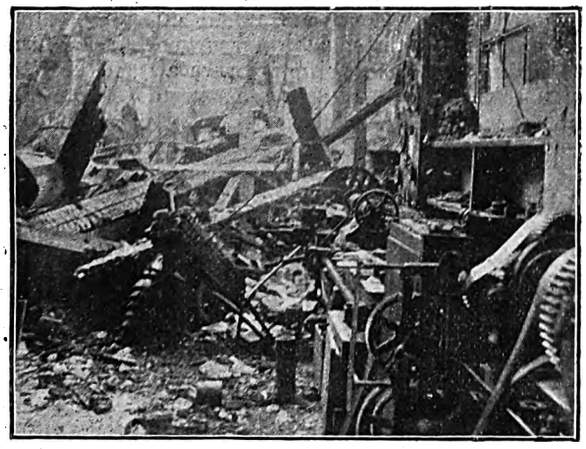
The damage wrought in the two or three short hours during which the fire lasted was almost incredible. Portions of the walls only remained standing, and these had all to be pulled down, so dangerous were they. In the engine room Willans engines were seen emerging from heaps of blackened rubbish. Lengths of copper rod, in twisted and fused masses, lay mixed up with bent girders, charred *débris*—representing chiefly the contents of the drawing office—and fallen brickwork. What was once the machine and fitting shop was, as will be seen by the accompanying views, a confused mass of lathes, planing machines, girders twisted into all shapes, broken castings,



Armature Shop. (1st floor).

remains of armatures, shafting, &c. The task of pulling down the remains of the walls was carried on through Sunday and Monday. The portions of the works saved include the dynamo and lamp stores, the switch and lamp shops, and the pattern stores. The carpenters' shop, the smithy and the boiler house being separate from the main block, also remained unhurt.

On Friday night Chelmsford was in darkness. The power department, however, got to work with a portable engine and a 400-volt Crompton arc-lighter, taken from stores, and which was run up to 700 volts on the emergency. On Saturday night every alternate arc lamp through the main thoroughfares was alight. By Tuesday night more than half of the incandescent public lighting was also in use.



Machine Shop. (Ground floor).

There is an obvious moral for general edification and warning to be drawn from this regrettable conflagration. But we are not disposed to draw it, at any rate just at present, preferring to-day to express our sympathy with a firm which is endeavouring so pluckily and so promptly to repair the consequences of a great disaster which has overtaken it at an unusually busy time.

THE BEHAVIOUR OF TRANSFORMERS UNDER THE INFLUENCE OF ALTERNATING CURRENTS OF DIFFERENT WAVE FORMS.*

BY DR. G. ROESSLER.

(Continued from page 126.)

After the foregoing explanation of the procedure for the interpretation of the readings of the measuring instruments, an example is given to show the accuracy which may be expected of the number of observations, and the method of tabulation.

Each of the values given in the results is the mean of a number of observations. The method of observation was so arranged that one observer took 10 readings of the wattmeter, while the other observer took as many observations as possible. Then, if a set of

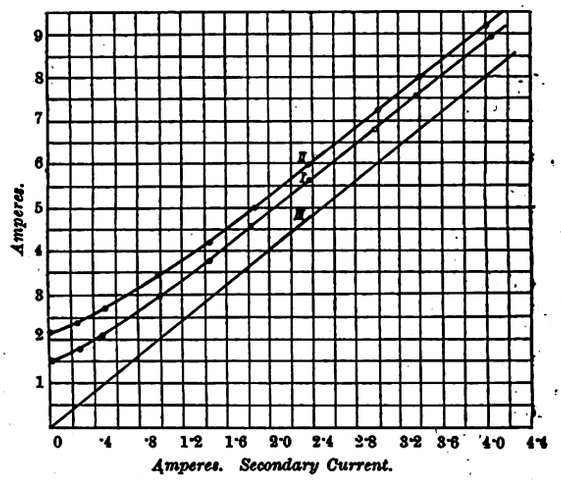


FIG. 7.—Primary Current. I. Ganz Machine. II. Wechsler Machine. III. 2 × Secondary Current.

speed observations showed no perceptible variation, the times occupied by the readings were very short, and varied little. Tables II. and III. give an example of a set of observations.

The lines denoted by similar figures in these two tables give the behaviour of the transformer under approximately-similar loads. A comparison of the values of the electrical quantities leads to the following important conclusion :—

For equal primary potential, and equal loading of the transformer, the primary current and power are smaller, and the efficiency is thereby greater, when the Ganz machine, with pointed potential curve, is used to supply the electrical power. The regulation of the secondary potential E_{p_2}, on the other hand, is better when the Wechsler machine, with approximately sinusoidal potential curve, feeds the transformer.

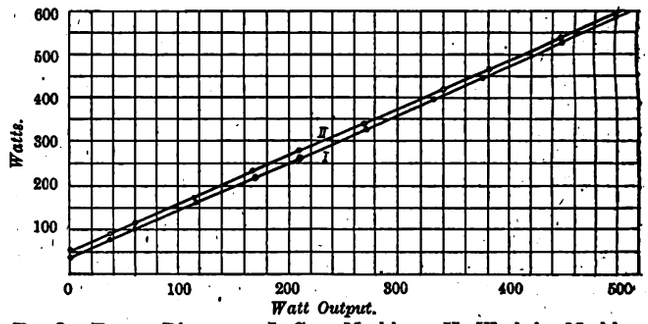

FIG. 8.—Energy Diagram. I. Ganz Machine. II. Wechsler Machine.

The differences in J_1 and A_1 are very great, especially for low loading of the transformer. As an illustration, the primary winding takes, with the Wechsler machine, one and a-half times as much energy, and one and a-half times as much current as with the Ganz machine. When one considers that a transformer in connection with a central station is, for the greater portion of the day, working at very low loads, these quantities become very important items in the working of the system, and we see that the form of the potential curve is of great significance in the economy of a transformer system.

Also, at higher transformer loads, there are great differences in the values J_1, A_1 and η, depending on the form of the potential curve. Fig. 7, which shows J_1 as a function of J_2, and Figs. 8 and

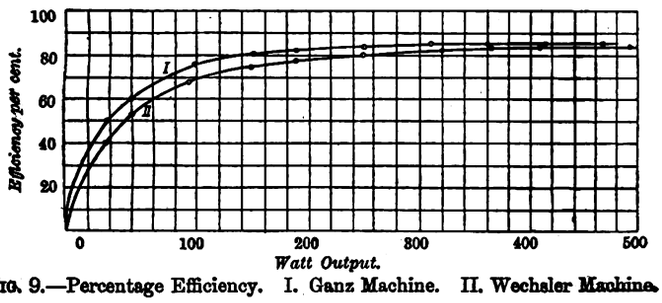

FIG. 9.—Percentage Efficiency. I. Ganz Machine. II. Wechsler Machine.

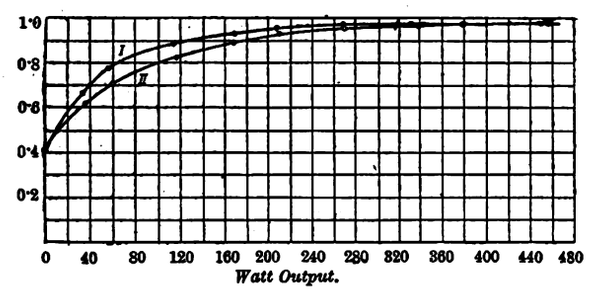

FIG. 10.—Power Factor. I. Ganz Machine. II. Wechsler Machine.

9, which give A_1 and η as functions of the load, show these differences more clearly. It is worthy of remark (Fig. 10) that the ratios of the power A_1 to the apparent power Ep_1J_1, for both sets of measurements, are not very different. If all the waves were sine curves, then $\frac{A_1}{Ep_1J_1}$ would be the cosine of the phase difference between the primary current and potential. In practice, the influence of the magnetic properties of the iron renders the current curve unsymmetrical, and the phase difference of the maximum points differ from that of the null points. The lag is therefore unknown, and the quantity $\frac{A_1}{Ep_1J_1}$ loses its geometrical signification. In practice, however, this quantity has a very important bearing in judging of the behaviour of a transformer; for calling $\frac{A_1}{Ep_1J_1}=F$, then $A_1=Ep_1(J_1F)$, the quantity J_1F being that portion of the current which is used in giving out power, while the power lost in the leads to the transformer depends on the *total* current. The quantity F has this meaning in the above table, and is called the "power factor." In consequence of the approximate equality of the values of F at high loads in both cases, where Ep is kept constant, the quotients $\frac{A_1}{J_1}$ are nearly equal. The values of A_1 and J_1 alone, however, are very different; hence the extra current taken by the transformer when run off the Wechsler machine, as compared with what it takes when run off the Ganz machine, is in much the same proportion as the extra power.

The values of the secondary potential Ep_2' occupy the last column in the table. These numbers are calculated from the observed values Ep_2 in the seventh column, on the assumption that Ep_2 varies an equal percentage, up or down, as Ep_1 varies from 60 volts; Ep_2' is thus the secondary potential which results when $Ep_1=60$ volts. For the open circuit measurements no reading was made of the secondary potential, since for this measurement the Cardew voltmeter had to be used, which took 0·3 ampere, which is an appreciable part of the normal load of the transformer. From the curves, Fig. 11, which graphically represents the drop of potential, it is seen that the secondary potential

Digitized by Google

on open circuit would be 117·5 volts with both machines. From the ratio of the windings this value should be $E p_2' = 60 \frac{265}{132} = 120{\cdot}45$; thus the transformer on open circuit has a drop of 2·5 per cent. for magnetisation. At the normal load of 480 watts the potential with the Wechsler machine is 115·7 volts, whilst with the Ganz machine it is 114·5 volts. With the peaked potential curve $E p_2'$ is thus 1 per cent. smaller. When one considers that the potential drop at no load shows an exceedingly bad magnetic circuit, which increases also the drop at higher loads, and compares this defect with the great differences of the primary current and power at low loads, this objection to the peaked potential curve will appear of small consequence in comparison with its great advantages.

The great influence of the form of the wave on the efficiency of transformers, which is shown by the foregoing measurements, makes the choice of the curve form a matter of great importance. The results are admittedly only given for one transformer, yet

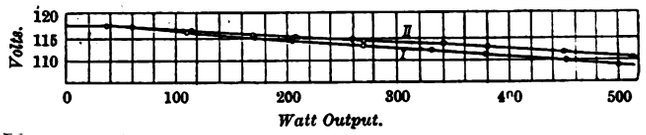

FIG. 11.—Secondary Voltage. I. Ganz Machine. II. Wechsler Machine.

their general applicability is manifestly justified if the differences found admit of a general explanation not depending on any peculiarities in the circumstances of the investigation under consideration. In order to get a clear idea of the foregoing facts, which have as their result a great difference in the behaviour of the transformer, I will now give the potential and current curves of both machines for no load, and for various loads on the transformer.

Shape of the Potential and Current Curves.

The fixed points of the curves were determined by the method brought before last year's meeting, by means of a contact apparatus fixed on the shaft of the alternator, which could be turned on the

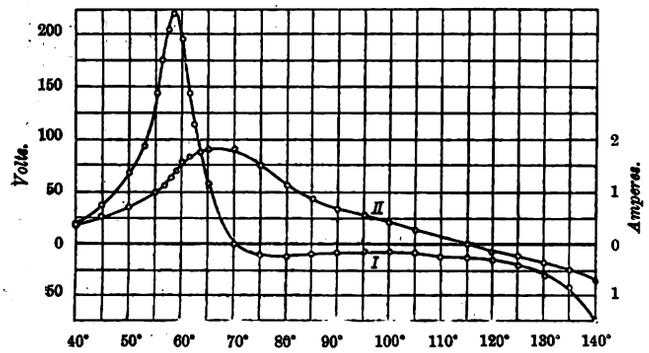

FIG. 12.—Ganz Machine. I. Primary Voltage. II. Primary Current.

shaft, and was connected in such a manner that, at each turn, it gave a momentary connection between the alternator terminal and a condenser, for different positions of the armature in the field. Through the uniform and rapidly-repeated (1,217 times per

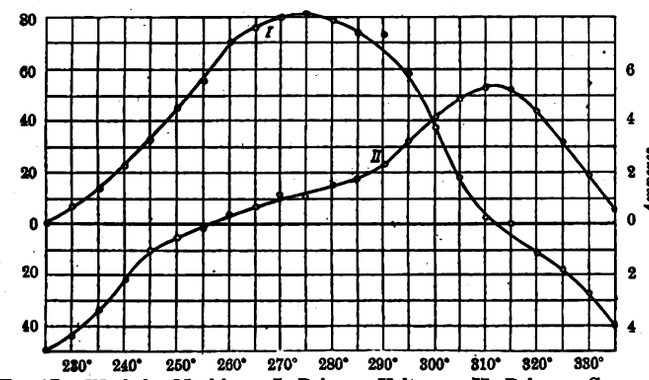

FIG. 13.—Wechsler Machine. I. Primary Voltage. II. Primary Current.

minute) charging of the condenser, it attains a constant potential, which can be measured directly by a Carpentier electrometer, idiostatically connected, or by discharging the condenser through a ballistic galvanometer. Since the alternator terminal is not always, but only for an exceedingly short part of each revolution, in contact with the condenser, there is a small amount of discharge between the successive contacts, and the mean potential difference on the condenser is smaller than the momentary potential difference on the transformer. This error was eliminated by considering the readings of the instrument as empirical, a known variable potential difference derived from a compensation apparatus of the Physikalisch-Technischen Reichsanstalt being introduced in place of the alternator. The variation of the current was determined by the variation of the potential difference across a known inductionless resistance. For the investigation of the current and potential curves at no load the electrometer only was used; for the loaded transformer the ballistic galvanometer was used for the two potential curves, and the electrometer for the current curves. Both instruments were connected alternately to the primary and secondary circuits by a switch. In each set of measurements the readings with the two instruments are taken one immediately after the other.

The results of these measurements are as follows:—

The potential and current curves given by these tables are shown in Figs. 12 and 13, for the Ganz and Wechsler machines respectively. From these figures it will be seen that the current curve differs widely from the potential curve in both machines. With the Ganz machine the potential curve is very pointed, the current curve very flat; with the Wechsler machine the potential is almost a sine curve, but the current curve is not so flat. These differences exhibit in an interesting manner the influence of the magnetic properties of the iron on the shape of the current curve. The relation between the current and potential is given by the equation

$$E p_1 = J_1 w_1 + n_1 \frac{d N}{d t},$$

where $E p_1$, J_1 and N are, respectively, the instantaneous values of the primary potential, current, and the magnetic flux cut by the coil, and w_1 and n_1 are the resistance and number of turns of the primary coil.

If H is an instantaneous value of the magnetising force due to the current J_1, B the resulting magnetic induction density, s the section of the iron core, and l the mean length of a line of force, we have the equations

$$H = 0{\cdot}4\pi \frac{n_1}{l} J_1$$

and

$$N = Bs.$$

Hence we get the equation

$$E p_1 = J_1 w_1 + n_1 s \frac{d B}{d H} \frac{d H}{d t}$$

$$= J_1 w_1 + 0{\cdot}4\pi \frac{n_1^2}{l} s \frac{d B}{d H} \frac{d J_1}{d t}.$$

Digitized by Google

for all forms of the potential and current curves. If the permeability of the iron were constant we should have $\frac{dB}{dH}=\mu$ constant. But in practice $\frac{dB}{dH}$ is the trigonometrical tangent of the angle which a geometrical tangent to the hysteresis curve makes with the + direction of H; hence, for a given current J_1, the variation of Ep_1 depends greatly upon the hysteresis curve, and *vice versâ*. This influence of the hysteresis curve upon the shape of the curves Ep_1 and J_1 is clearly shown in Figs. 12 and 13.

If J_1 attains its maximum value, $\frac{dJ}{dt}=0$, and as $J_1 w_1$ is always very small Ep_1 has a very small value. The figures demonstrate this point. If, also, the alternator gives a very pointed potential curve, and very high maximum value, the maximum value of $\frac{dB}{dH}\frac{dJ_1}{dt}$ must be very great. But $\frac{dB}{dH}$ is independent of the alternate-current curve, and only depends on the hysteresis curve, hence the value of $\frac{dJ_1}{dt}$, which is simultaneous with the maximum value of the potential, must be greater with pointed curves than with flat. Simultaneously with the maximum value of the potential, for flat curves, there is a slower rise of current than in the case of peaked curves. It is thus evident why the current curve with the Wechsler machine, at the ordinate where Ep_1 is a maximum, is flat, and why J_{max} is sharper than Ep_{max}. These peculiarities of the current curve are always to be expected when the current-producing machine gives a sine potential difference. Simultaneous sinuous variations of Ep_1 and J_1 never exist; the form of the current curve is always very different from that of the corresponding potential curve.

In the present case there is a lag with the Ganz machine, between J_{max} and Ep_{max}, of about 11·5deg.; and between the null points of these curves a phase difference of 46deg. With the Wechsler machine, the maximum points and null points are 30deg. and 35deg. apart respectively. In general, for any potential curve, the magnitude of the lag is not greater. The phase difference cannot be given for the whole of the curves, but only for the characteristic points.

Planimetering the curves we have :—

Table V.

*With the Ganz Machine.**

$M(Ep_1)=36{\cdot}9$ V, $M(J_1)=0{\cdot}733$ A,

$\sqrt{M(Ep_1)^2}=62{\cdot}5$ V, $\sqrt{M(J_1^2)}=0{\cdot}938$ A,

$c=\frac{M(Ep_1)}{\sqrt{M(Ep_1^2)}}=0{\cdot}590$, $c=\frac{M(J_1)}{\sqrt{M(J_1^2)}}=0{\cdot}782$.

Also

$Ep_{1max}=219{\cdot}0$ V, $J_{max}=1{\cdot}82$ A,

$K=\frac{\sqrt{M(Ep_1^2)}}{Ep_{1max}}=0{\cdot}285$, $K=\frac{\sqrt{M(J_1^2)}}{J_{max}}=0{\cdot}515$.

With the Wechsler Machine.

$M(Ep_1)=45{\cdot}25$ V, $M(J_1)=2{\cdot}378$ A,

$\sqrt{M(Ep_1^2)}=53{\cdot}83$ V, $\sqrt{M(J_1^2)}=2{\cdot}922$ A,

$c=\frac{M(Ep_1)}{\sqrt{M(Ep_1^2)}}=0{\cdot}841$, $c=\frac{M(J_1)}{\sqrt{M(J_1^2)}}=0{\cdot}814$.

Also

$Ep_{1max}=81{\cdot}1$ V, $J_{max}=5{\cdot}35$ A,†

$K=\frac{\sqrt{M(Ep_1^2)}}{Ep_{1max}}=0{\cdot}663$, $K=\frac{\sqrt{M(J_1^2)}}{J_{max}}=0{\cdot}546$.

(To be continued.)

Superfluous Tracks.—The Street Railway Association of the State of New York has been asking itself the heart-searching question: "Are we laying too many miles of track to reach a few people?" It came to the conclusion that it is not, and found that the tramway lines are far more profitable than the trunk railway lines. The conditions favourable to the success of tramway enterprise were discussed, and the curious opinion given that "all parks and pleasure resorts introduced along existing lines, even though built at a considerable expense, if properly managed, will prove a booster to the net receipts of the lines."

* In this table $M(Ep_1)$ and $M(J_1)$ represent the simple mean of the varying values of Ep_1 and J_1. $\sqrt{M(Ep_1^2)}$ and $\sqrt{M(J_1^2)}$ are the R.M.S. values.

† Taken from the current curve in Fig. 13.

WHICH ELECTROLYTIC METHODS CAN BE USED WITH ADVANTAGE IN ANALYTICAL PRACTICE?*

BY DR. BERNHARD NEUMANN.

This article, which, through considerations of space, we have been unable to reproduce in full, contains much valuable information, and is so replete with references that it forms a veritable index to the literature of the subject.

The history of electrolysis is traced from the time of the elder Becquerel (1823) to the discovery of electroplating by Jacobi (1839), and it is shown how the experience gained by Messrs. Elkington, Ruolz and others in this work was turned to account to yield analytical tests for the presence in food of small quantities of certain metals (antimony, arsenic, copper, lead and mercury). These methods are in partial use to this day. The first notice with respect to the employment of the electric current for chemical analysis dates, however, from a much earlier period, and is found in the works of Davy in 1805. But the elder Becquerel must be considered the real father of electro-chemical analysis. He found out in 1830 a practical method for the separation of small quantities of lead and manganese from other metals. He separated these as a peroxide at the positive plate from acetic acid solution. In this way he separated iron from manganese. He showed further that 1 gramme of the manganese acetate could be completely separated in about 24 hours. The real experiments to introduce electrolytic methods as an assistance in practical quantitative analysis date only from the beginning of the '60's. Thus W. Gibbs in 1864 showed, after previous experiments, how the copper could be plated from a sulphuric acid solution of the coinage alloy of copper and nickel. At the end of the communication he mentioned that the nickel also can be separated by the current, and even from the same solution, by rendering it ammoniacal. In 1865 C. Lückow communicated his experiences with electrolytic separations to *Dingler's Journal*. Since that date a great number of most widely differing propositions for the quantitative estimation of metals are to be found scattered throughout the literature of the subject; but statements as to the applicability and usefulness of electrolytic, as compared with gravimetric and volumetric methods of analysis, are rather scarce. In May, 1867, the Mansfeld Ober-Bergund Hütten Company, at Eisleben, published a prize essay on the discovery of a copper test for the rapid determining of the metallic contents of the Mansfeld slates. At the same time an electrolytic method proposed by C. Lückow was distinguished by an award.

In order to discover the methods which are most suitable in practice, it is best first to answer the general questions: What is required of an electrolytic method in order that it may be employed with advantage in place of those ordinarily used in analysis, and what are the conditions under which electrolysis is specially applicable? It is only after these questions have been answered that one can proceed to consider which substances can be determined electrolytically, which are the particular methods which offer a real advantage over those ordinarily employed in analysis, and what these advantages are. The choice of an electrolytic in preference to a gravimetric or a volumetric method will be determined by considerations corresponding to those which would be taken into account in deciding which of the two latter forms of analysis to employ. There is no chemist who, out of love for the one kind of quantitative determination, would carry out all his analyses either only by the gravimetric or only by the volumetric method, for then time and accuracy could not be taken into account. A titration is generally quicker than a gravimetric method, but the latter is more often employed because of its superior accuracy. It is just the same with electrolysis. Out of the great number of proposed methods, a considerable number give, with the precautions directed, analytically useful results; but despite that, they are not suitable in practice. The chief advantage of electrolysis lies in the great simplicity of the whole manipulation, consisting as it does in first putting the electrodes into the liquid, regulating the conditions of the current, and at the end, after the separation has been accomplished, stopping the current, washing the one electrode in water and alcohol, and drying and weighing it. The whole operation takes up very little time. Besides that, in most cases the substance sought is weighed direct as metal, and so every calculation is avoided. A much greater advantage is that by the employment of two or three accumulators a whole series of analyses can be carried on at the same time without their interfering with each other. Electrolysis is, therefore, under certain circumstances, a very useful auxiliary in the laboratory of the analyst.

In the choice of electrolytic methods the factors time and accuracy naturally are the guides. The analyst as well as the works chemist must often require that their analytical methods should give accurate results in a given short time. Leaving time out of

Digitized by Google

consideration, it is always desirable that the electrolytic process employed should be one that can be watched throughout its whole course. Hence it arises that a great number of methods are not usable because they do not satisfy these requirements; such are all the processes which only yield "over-night" results whose duration lasts from 12 to 24 hours and more. Also all those in which a metal is separated from a solution in which it is contained in the form of a complex salt, especially as double salt of cyanide of potassium and pyrophosphates, and also from oxalates, tartrates and caustic potash or ammoniacal solutions. Take, for example, the separation of copper; we find solutions of neutral salts, with free nitric acid, sulphuric acid, ammonia, oxalate, tartrate, phosphate and cyanide of potassium solutions and others suggested. The time required for the deposition 0·25 Cu (= about 1 gramme $CuSO_4$) amounts to about 1½ to 2 hours for neutral, nitric acid, sulphuric acid, and oxalic acid solutions, with a current density of 1 ampere for 100 sq. cm. The deposition in the presence of ammonia requires only a very weak current, and is ended in 6 hours with 0·2 ampere. That from potassium cyanide and phosphoric acid solutions requires still longer. One of the first methods is therefore to be chosen. But it is not immaterial which. That method is always to be preferred which allows of the deposition of the metal from the solutions yielded direct in practice. Therefore the choice falls on the nitric acid and sulphuric acid methods. Moreover, in the case of the nitric acid, sulphuric acid and neutral solutions (when the neutral salt is copper sulphate), electrolysis can be left to itself; whilst in the case of the oxalic acid bath constant attention is required, since the continued addition of oxalic acid is necessary if the metal is to be deposited in a usable form. The quantity of metal which can be separated in an adherent form, and the character of the deposit, must also be considered, since, unless the latter is metallic, bright and shiny loss is apt to occur in washing and drying it. A method to be useful must also allow of variations in the current strength within certain limits. The conditions of electrolysis are such that by its means at least as accurate results could be obtained as by any other analytical method, but that the current does not always act on the metal required alone. Attempts have been made to obtain separations of the metals by varying the conditions of electrolysis; for instance, lead and copper have been separated, the former being deposited on the anode as peroxide, while the latter metal goes to the cathode. Also, by the addition of strong mineral acid, the deposition of iron, &c., has been prevented, thus separating them from the noble metals. Freudenberg has also shown that by paying attention to the voltage a large number of separations can be effected, since the metal with the lowest decomposition potential is deposited first. In practice, only the separations of the first kind and some of the second are suitable, the others requiring too much time; but it has been established by experience that it is generally better only to use electrolysis in the case of pure or almost pure solutions which have been obtained by ordinary chemical methods. The constituent parts of an alloy can all be determined by electrolysis as an exercise, but that is not sufficient for the practical analyst.

Before discussing particular methods it is necessary to remember that substances are separated at both electrodes. At the cathode hydrogen and the metals are separated, of which only the latter are used for analytical purposes. At the anode oxygen, halogens, sulphuric and carbonic acids, and other substances are freed, of which only the two first are of any use for analysis. Now, while the employment of peroxide dates from the '30's, the endeavour to make the halogens appearing at the anode analytically valuable is still rather recent. Kinnicutt and Whitefield (1887) had published indirect methods for their estimation; but Vortmann (1894) has shown that the halogens can be quantitatively determined if their separation takes place at a silver anode—that is to say, at an anode which can combine with them. Both electrodes must be weighed, since some silver goes into solution at the anode, and is deposited at the cathode. In a similar manner the author has separated fluorine from a soluble fluorine salt, using an aluminium electrode. Experiments are still in progress, but the method can never have more than a theoretical value, since the quantity of the halogen which can be fixed is limited by the surface of the anode, and also because an electrolytic separation of the different halogens is not possible. A whole series of metals (silver, bismuth, manganese, lead, thallium, cobalt and nickel) separate at the anode as peroxides, but the majority of them are also simultaneously deposited at the cathode, so that only lead and manganese can be estimated practically as peroxides.

Manganese.—This metal separates out from solutions of neutral salts, or solutions acidified with sulphuric, nitric, and acetic acids. The formation of peroxide takes place best in the presence of free acid, but if there is more than 3 per cent. of nitric acid, permanganic acid is formed and there is no deposit. Classen recommends the acetic acid solution which had already been used by A. Becquerel in 1830. But as even by this method only 0·15 gramme manganese can be deposited under the best conditions, and doubt exists as to the exact nature of the deposit, electrolysis is not satisfactory for the determination of this metal.

Lead can be deposited either in the metallic state at the cathode, or as peroxide at the anode; but it is only in the latter form that it can be estimated accurately. The separation takes place best from a nitric acid solution which Lückow showed in 1865 must contain not less than 10 per cent. free acid if all the lead is to be separated as peroxide. The deposit may contain traces of bismuth and silver, but Lückow states that in a 15 per cent. solution of nitric acid, to which a few drops of oxalic acid have been added, no silver goes to the anode. The best current density is from 1 to 2 amperes per 100 sq. cm., with a potential difference of from 2·3 to 2·7 volts, and the temperature should not exceed 60°C. to 70°C., for the peroxide is apt to fall off. The peroxide contains water, and according to Classen drying at 130deg. is not sufficient, but a temperature of 180deg. to 190deg. is required.

Iron.—A large number of solutions for the electrolytic separation of iron have been proposed, but they none of them yield as accurate results as can be obtained by the ordinary analytical methods. Electrolysis, however, is useful as a means of obtaining pure iron for standardising purposes.

Cadmium.—This metal is an exception to the general rule that metals which are precipitated by hydrogen sulphide in acid solutions can also be deposited electrolytically from such solutions. It belongs electrolytically to the series of metals which have a greater ionising tendency than oxygen, and hence it follows that it cannot be deposited in strongly acid solutions. Lückow has found that 1 to 2 per cent. of free sulphuric acid is the utmost limit permissible, and that with most of the solutions proposed it was only with the greatest difficulty that a bright, silvery deposit could be obtained, as it has a great tendency to come down in a spongy form. The amount of the metal which can be deposited (0·15 gramme) is too small to be useful for purposes of analysis. From caustic potash solutions the cadmium separates better, but the time required is very long, only 0·08 to 0·09 gramme being deposited per hour. It is not practically possible to separate cadmium electrolytically from other metals, and therefore ordinary chemical means must be resorted to, and the cadmium sulphide thus obtained can be more easily estimated gravimetrically than by electrolysis.

Cobalt and Nickel.—The conditions for the successful electrolysis of these two metals are so similar that they may be considered together. Both metals separate imperfectly from solutions of their neutral salts, but the addition of a little acetic or other acid remedies this; excess of acid prevents the deposition. The simplest method, and the only one used in practice, is that introduced by W. Gibbs in 1864, which consists in supersaturating with ammonia their sulphuric acid solutions. Schweder, who used this method in the analysis of ores and coinage, recommends the addition of a great excess of ammonia in order to prevent the separation of peroxide. Fresenius and Bergmann find that the best conditions are obtained with a solution containing 0·1 to 0·15 gramme nickel as sulphate, 6 to 9 grammes ammonium sulphate, and a minimum of 2·5 to 4 grammes ammonia. The proportion of ammonium sulphate need not be accurately maintained, but the ammonia must be in excess throughout the whole operation, although too great a quantity retards the separation. The same applies to cobalt. The author has got good results from a solution containing ten times as much nickel as that given above, and Winkler, who used the electrolytic method for obtaining pure cobalt and nickel for the purpose of determining their atomic weights, has also found that the proportion of nickel may be increased without detriment. The best current density to employ is 0·5 to 1·5 amperes per 100 sq. cm. at a pressure of 2·8 to 3·3 volts at the ordinary temperature. Experiment has shown that two hours is sufficient to deposit all the nickel from 1 gramme of ordinarily rich ore or alloy. The Mansfeld Ober-Bergund Hüttendirektion employ a solution of nickel chloride and ammonia, but find that an excess of ammonium chloride or of nitrates disturbs the results, and this is confirmed by Wrightson. The advantage of the electrolytic determination of nickel is that in alloys, and ores which have been dissolved in acid, all metals, except iron, cobalt, nickel, zinc, manganese and aluminium, can be separated by electrolysis, or precipitated by hydrogen sulphide. The electrolytic determination of nickel is one of the methods which can be used with real advantage, and is much to be preferred to the gravimetric methods of analysis, where only small quantities of nickel are concerned.

Zinc is another metal which cannot be deposited in strongly acid solutions. In solutions of neutral salts it comes down in a spongy form. But the addition of sodium acetate or of a small quantity of free acid, such as acetic, remedies this. Solutions of ammonium acetate, ammonium oxalate and cyanide of potassium also give good results. The zinc deposit on the cathode appears to alloy with the platinum, and is only removed with difficulty; therefore it is advisable to first plate that electrode with silver or copper. Even with the best methods the deposition is slow, 0·15 to 0·2 gramme being deposited in about two hours, with a current density of 1 to 1·5 ampere. As in the case of iron, nickel and cobalt, the last traces of zinc are only removed from the solution with

Digitized by Google

difficulty, and a current density of at least 1 ampere must be maintained to the end. A portion at least of the failures in the electrolysis of zinc are due to a neglect of this precaution. As the electrolytic determination of zinc is slow and attended with difficulty, it cannot compete with ordinary analytical methods, since the zinc must first be separated from other metals by chemical means.

Gold.—This metal can be easily plated out from a neutral solution of its chlorine, and from solutions of various of its salts. But electrolysis cannot be employed in analysis, since the gold is apt to be deposited in a powdery form, and as the weight of the electrode is large compared to that of the gold, the results are not accurate. Before electrolysis also the gold must first be separated chemically from silver, copper and bismuth.

Bismuth.—Electrolysis of its solutions yield either the metal, or mixtures of the metal and peroxide, according to their nature. The latter are yielded by solutions of the neutral salts, and by those containing free nitric acid. From sulphuric acid, oxalic acid, and some other solutions the metal alone is obtained at the cathode, but as it is nearly always deposited in a black and powdery form, the electrolytic method of determination is not suitable for analytical purposes.

Arsenic.—This metal cannot be deposited at all from acid solutions, and only imperfectly from neutral ones.

Silver.—As in the case of bismuth, the electrolysis of many silver solutions yields the metal at the cathode, and peroxide at the anode. With nitric acid solutions the formation of peroxide ceases on greatly diluting them, and employing a very weak current. The cyanide bath yields good results with a current of 0·02 to 0·05 ampere per 100 sq. cm. and a potential difference of 3·5 to 4·5 volt, at the usual temperature. Unless, however, the silver has been freed from copper, gold, mercury, cadmium and other metals, they are deposited with it if the potential difference is not kept below 1·7 to 1·8 volts, at which voltage the rate of deposition becomes so slow as to be useless for practical purposes. Since pure silver solutions rarely require to be examined, the ordinary dry and wet methods give quicker results than the electrolytic.

Mercury.—The separation of mercury from other metals is possible (in nitric acid and cyanide of potassium solutions), but only under the conditions which obtain in the case of silver. For the determination of mercury in ores containing other metals Rose's dry method is preferable. But for the estimation of mercury in pure ores electrolysis in chloride or sulphate of sodium solutions can be advantageously employed. The latter method is in practical use in the case of cinnabar at Almaden, in Spain.

Copper.—An electrolysis for its determination was first used by Gibbs in 1864, as has already been mentioned, and at the same time it was also employed by Lückow in the estimation of the amount of copper in the fireboxes of locomotives, who found that the quantity of free acid present should not exceed 8 per cent. Various solutions have been suggested, but only the nitric and sulphuric acid are employed in practice. In this way the copper is freed from iron, cobalt, nickel, cadmium, zinc and manganese, which cannot be deposited from strongly acid solutions, but large quantities of iron act prejudicially. Lead in nitric acid solutions is deposited on the anode as peroxide, but any silver, bismuth, mercury, arsenic, antimony and tin which may be present, go to the cathode with the copper. Arsenic, antimony and tin only come down after the bulk of the copper has been deposited, but no complete separation can be effected in this way. Freudenberg states that an electrolytic separation can be made if the voltage does not exceed 1·2 to 1·3 to 1·9 volts. But this method is more applicable to the preparation of pure metal than to commercial purposes. Copper can be easily separated from all other metals by chemical means, but as in most cases only a few are present, the electrolytic method can almost always be used with advantage, and the results obtained are as accurate as those yielded by other analytical processes. The best conditions of electrolysis for a copper solution containing 8 to 10 per cent. free nitric acid are a current density of 1 to 2 amperes per 100 sq. cm., at a potential difference of 2·2 to 2·7 volts, the temperature being 50°C. to 60°C. The current density, however, may rise to over 3 amperes without injuring the character of the deposit, but the amount of copper deposited does not increase proportionally to the increase of current. The same conditions apply to sulphuric acid solutions containing 3 per cent. free acid.

Antimony.—For the electrolytic determination of this metal a solution of the sulphate in sodium sulphide is recommended. For a solution containing 50 to 70 per cent. of a cold, saturated solution of sodium sulphide, the best conditions are a current density of 1 to 2 amperes per 100 sq. cm., at a potential difference of 1·3 to 3 volts. The electrolysis can be effected at the ordinary temperature, but is shortened by raising it. Thus 0·3 to 0·4 gramme antimony can be deposited in 1½ to 2 hours, at a temperature of 80°C.

Tin.—This metal can be plated out of various solutions, but the only one used in practice is the ammonium sulphide. The electrolytic method is particularly suitable for the separation of the antimony-arsenic-tin group. The solution containing these three metals is first freed from arsenic by means of ammonium carbonate, and then the antimony is plated out as described above; 20 to 25 grammes ammonium sulphide are added, and the solution boiled 10 to 15 minutes, and electrolysed when cold. The best conditions are a current density of 1 to 2 amperes, with a potential difference of 3·3 to 4 volts, and, as in the case of antimony, the deposition takes place more quickly at a higher, though the metal plates out well at the ordinary, temperature. The electrolytic method of analysis is very useful in many cases. On reviewing the electrolytic methods, it appears that many of them offer real advantages over those usually employed. This is more especially so in the case of lead, copper, nickel, and antimony, but on the other hand there are metals, such as iron and manganese, for which they are unsuitable, and in the case of the other metals circumstances will decide what method to adopt. Nissenson's and Rust's reports on the analyses carried out in the laboratory of the Stolberg Company in 1892 show the aid which can be given to the analyst by electrolysis. Experience has proved that accumulators are by far the most useful source of current for electrolytic determinations, and they may be charged by means of a thermopile if the necessary power to drive a dynamo is not available. No form of primary battery gives satisfactory results, and if accumulators cannot be employed, a Gulcher thermopile is recommended. Platinum is the only material to be used for the electrodes; platinised tin is not durable. Various forms of electrodes have been recommended, but in practice only two are found, and the selection between these may be left to the analyst. One sort consists of a cylinder of platinum foil as cathode, split up at the side and open at the top, whilst the anode consists of a cylindrical spiral of platinum wire contained within the cathode. The electrodes are immersed in a beaker which contains the solution to be electrolysed. The openings allow of the metal being deposited on both sides of the cathode, and facilitate its removal. In the second typical form of apparatus the cathode takes the shape of a bowl which contains the electrolyte, whilst the anode is a piece of platinum curved to the shape of the bottom of the bowl. This latter form of apparatus is objected to by some on the ground that, on the stoppage of the current, the cathode cannot be freed from the electrolyte and washed as rapidly as can the cylindrical cathode; but experiment shows that in skilled hands the inaccuracy caused by this delay is inappreciable. In conclusion, the author states that the reason that electrolysis has not found as universal admission to the laboratory of the analyst as it deserves, is owing to the fact that the selection of useful methods from the many proposed is a matter of difficulty and causes waste of time, and that the unpleasantness and difficulty of management of the primary batteries formerly used did not encourage experiment. The analyst, however, who has once availed himself of the aid of electrolysis, either by the employment of accumulators or of the thermopile, will not again willingly do without it.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

SATURDAY, November 30th.

ROYAL SOCIETY.

4 p.m. Anniversary Meeting.

THE ELECTRO-HARMONIC SOCIETY.

8 p.m. Concert (Ladies' Night) at the St. James's Hall Restaurant (Banquet Room), Regent-street, W.

MONDAY, December 2nd.

ROYAL INSTITUTION.

5 p.m. General Monthly Meeting.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture: "Mechanical Road Carriages," by W. Worby Beaumont.

SOCIETY OF CHEMICAL INDUSTRY.

8 p.m. Meeting of the London Section at Burlington House. Paper to be read: "Alkali Manufacture by the Hargreaves-Bird System of Electrolysis," by J. Hargreaves.

TUESDAY, December 3rd.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Papers to be read: (1) "The Influence of Carbon on Iron," by John Oliver Arnold; (2) "The Dilatation, Annealing and Welding of Iron and Steel," by Thomas Wrightson.

WEDNESDAY, December 4th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. "Mural Painting with the Aid of Metallic Oxides and Soluble Silicates," by Mrs. Anna Lea-Merritt and Prof. W. C. Roberts-Austen.

FRIDAY, December 6th.

INSTITUTION OF JUNIOR ENGINEERS.

8 p.m. Meeting at the Westminster Palace Hotel. Paper to be read: "Considerations with respect to Water, Gas, and Electric Mains, &c., in connection with the Formation of Urban Roads and Footways," by J. Julian.

NOW READY.—Vol. XXXV. of "THE ELECTRICIAN," bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

The published price of Volumes previous to Vol. XXXV. is 12s. 6d., post free 13s. 6d. Many of these Volumes are very scarce.

INJUNCTIONS.

We have previously had occasion to comment upon the effect of certain legal decisions which have pressed severely upon electric lighting undertakings, and to discuss the principles which we have always understood to govern such cases. Central stations have frequently been threatened with injunction for nuisance alleged to be caused by their operations carried on in pursuance of statutory powers, but which powers were found to be an inadequate protection against this terrible engine of the law. In some cases the unlucky offenders have been able to escape on payment of a pecuniary ransom; in others the injunction has been granted absolutely or conditionally, thereby paralysing the station operations, or only permitting them a precarious existence with a threatening sword hanging overhead. We are not surprised, therefore, that under such circumstances electric lighting undertakers should have become restive, and should display extreme anxiety to escape from so uncomfortable a position. They say, and no doubt with truth, that they are made a mark for speculative actions, and are looked upon by neighbours who have small interests but great expectations as fair game out of which to make profit by threats of legal penalties, and they ask such protection for their works as is necessary to enable them to carry out their statutory obligations. These feelings found expression at a meeting held last week under the auspices of the City of London Electric Lighting Company, who have themselves passed under the harrow. The proceedings at this meeting were of a more or less private nature, but as we stated last week the meeting was attended by representatives of a good many Electric Lighting Companies and Local Authorities, both metropolitan and provincial, and we were informed that a suggestion was approved that a deputation should wait on the Board of Trade on the subject of the unworkable clause or clauses in the Electric Lighting Acts, which are described as enabling an individual to obtain an injunction to stop electric lighting works. As we do not

Digitized by Google

know all that passed at this meeting, nor the actual terms of the resolution adopted, we have no desire to criticise the language of the communication made to us; but as it accords very much with expressions we have heard elsewhere we should like to point out what appears to us to be a misunderstanding going very much to the root of the whole matter.

There seems to be an impression that the Electric Lighting Acts impose some liabilities or restrictions which have not been imposed upon the undertakers of other similar schemes, and that the omission or amendment of certain restrictive clauses is all that is necessary to secure the immunity which is desired. But the fact is that in order to secure such immunity, positive legislation would be required of an entirely novel character. It is true that Parliament habitually grants to railway companies and others power to compulsorily take lands which are clearly defined by the grant, and to do thereon acts which would otherwise constitute a nuisance liable to be restrained by injunction. In these cases, however, ample notices have to be given before the Bill is brought in, and persons whose rights are affected have an opportunity of being heard in opposition; but Parliament has, so far as we are aware, never granted, and we should doubt if it ever will grant, to anyone a roving commission, enabling the holders thereof to set up works for the purposes of their undertaking upon any piece of land which they may be able to acquire by purchase, and thereby to cause a nuisance to the surrounding neighbourhood, which has had no opportunity of expressing an opinion on the subject. It is no answer to say that compensation will be paid for any injury proved to be done. The very existence of the weapon of injunction shows that the law clearly recognises the fact that there are many injuries for which it is difficult to assess compensation, and some for which no pecuniary payment could compensate. The grant of such powers would therefore undoubtedly curtail the proprietary rights of individuals, and Parliament before ordaining any such curtailment has always hitherto required satisfactory proof, not only that the act to be done is for the public benefit, but that the site selected for the commission of this act is the most suitable one for the purpose, and that its selection is likely to entail the minimum of inconvenience to the public or individuals. There would be no such safeguards if this fundamental rule were relaxed, and although we should gladly see electric lighting undertakings relieved from such oppressive litigation as may sometimes savour of the nature of blackmail, we should hesitate before advocating a remedy which would secure such immunity at the cost of injustice to individuals, and not least because of the doubt we entertain whether it would prove to ultimately advance electric lighting interests.

The object of the Electric Lighting Acts was to afford undertakers facilities to lay their mains in streets, and generally to carry on their business so far as they might be able to do so without interfering with rights of property. Compulsory powers to acquire or diminish such rights were expressly withheld, because Parliament in this as in all other similar cases deemed that such powers could not be justly granted by a general Act, but that each case must be separately considered. It was assumed that undertakers might be able to find a site, as in many cases they do in fact, where the carrying on of their business would not be open to any objection, whether public or private. If in any instance this should prove impossible, it is open to them to apply by Bill in the usual way for compulsory powers, when a committee will decide whether a case has been made out for such a grant, after considering any objections that may be brought to their notice. Everyone, however, who seeks power to take away compulsorily the property of his neighbours, whether such property be land or only peace and comfort, must pass through the same narrow entrance, over which is written, "Every case on its own merits." There is no royal road to be sought for by a general enactment.

We can imagine that our good friends the gas companies will smile at what they may regard as the frantic struggles of their less experienced *confrères* to get free from the trammels of the law, which others have found long ago were not to be broken through. They will tell us that they too have gone through the mill, and have found their way out without resorting to any heroic remedy. They can point to the annals of the Courts which record injunctions against some of their fraternity, granted at the instance of neighbours who had the bad taste to dislike gasworks fumes quite as strongly as people in these later days abhor the rhythmic thud of engines and the soothing hum of dynamos. They have got over these troubles mostly by evincing a becomingly retiring disposition and settling their works at spots which, if not exactly solitudes, are inhabited chiefly by their own workpeople, and they will perhaps say that their competitors for public favour might find the same way out of *their* difficulties. The Board of Trade may give some help indirectly towards this desirable consummation in their forthcoming revised rules, by a new definition of "low pressure," but we hardly expect that if the proposed deputation should ever reach the Board it will be encouraged to hope for positive legislation in the direction they desire. We fear that so long as central station chimneys are found in close proximity to the residences or business premises of the wealthy, they will have to pay somewhat heavily for the luxury of their aristocratic associations. Meanwhile, who can withhold sincere sympathy from electric light concerns which are under statutory obligations to maintain the supply, but which nevertheless may at any moment have the misfortune to unearth a hard-hearted judge who will issue an immediate injunction at the instance of an angry suitor? Hitherto the wind has been tempered to the shorn lamb by the distinct disinclination of the Courts to allow injunctions to actually issue; and on this chance support we fear that electrical undertakers will have perforce to rely until electric lighting stations become eccentric in position instead of eccentric in behaviour.

REVIEWS.

The People of the Moon. By TREMLETT CARTER. (London: "The Electrician" Printing and Publishing Company.)

Before we had read a word of this book, we saw that it would present great attractions to the boy mind. Its title would attract much, its cover more, and its illustrations most of all. There is a suggestion of strangeness and horror about these last which causes a delicious thrill before ever the tale is begun.

The story itself is of the Jules Verne type, but the author has been at some pains to make his science as nearly accurate as may be, considering that most of it depends on a vivid imagination. Whether or not, for instance, it would be possible for persons to be changed into ether, transported through space, and re-embodied when they had reached their destination, is open to doubt—it is not a mode of travelling that we should care personally to try—but it seems pretty certain that if it *were* possible, our feelings would quite answer to the description of Mallâla's when he went to Tella by the lightning transmitter. "He felt an almost insupportable sensation of being torn limb from limb, and as if his entire body was undergoing dissolution.'

Digitized by Google

The desire for consistency in scientific foreshadowings has led to rather too many explanations, but the ordinary boy will probably imitate the example of Imberto's magnificent air ships, and, when he sees an avalanche of rocky scientific terms, he will swiftly avoid the obstacle and steer his previous delightful course. He will travel through a strange country indeed, and among an almost bewildering variety of marvels; he will meet with a metal that repels matter instead of attracting it, a viaduct with no visible means of support, a granite-boulder-eating dragon, grapes made from the ether, "annihilators" capable of destroying a whole town at one fell swoop, gemmating giants, and the lightning transmitter already alluded to.

It appears that the present inhabitants of the moon, or Oolaâla, as they call it, live, not on its surface, but in the interior, in a series of huge rocky caverns and tunnels. It is true that there were two races of beings on the surface when this veracious history was begun, but one of these killed off the other, and was in its turn destroyed by a sort of moon-quake, if we may coin the word, so that we should now search in vain for any traces of either.

Indra, Prince of Sarâva, the kingdom of the interior of the moon, started off on an expedition to the surface, the very existence of which was denied in Sarâva, in search of a lady with whom he had fallen in love in a vision. On his arrival, after a series of most thrilling adventures, he was accidentally precipitated into space, with a whole inverted basin full of zukâra—the metal that repels matter—in the cage with him, and next to no matter of the usual heavy sort to counteract it. The result was unpleasant. When he awoke from the swoon into which he had fallen, he found himself literally "All among the little stars, sailing round the moon." His sensations when he discovered himself to be some hundred thousand miles or so away from the Oolaâla are very graphically described; but the part that gave us the most deliciously horrible thrills, as of cold water running down one's back, was the description of his leap from his cage through the final six thousand miles that separated him from the moon. To fall alone through silence and darkness, for seven days and seven nights—what a gruesome conception!

Among them, the people of the moon seem to have carried scientific research and invention to a pitch at which we poor earth mortals can hardly hope to arrive in the course of another thousand years or so. Indeed, one race became extinct before this story was written, by reason of the very perfection of its mechanical devices; for it had reduced life to such a complete system of button-pressing that its members grew too weak and lazy to take care of themselves, and were all carried off one fine day and immolated on a mountain top by a race of giants—an awful warning to such as would trust too implicitly to the devices of inventors.

There is one power which we confess we envy the Sarâva more than any other—that is the power to enjoy a lightning bath. We are told of the "ineffable enchantment of a plunge into such a perfect electric torrent as was now raging." "Into their very lungs they breathed the vitalising and energising electric force; and as the tingling action thrilled through their frames, they felt themselves renewed in the strength and elasticity of both mind and body."

We hardly like to point out literary blunders in so lively a book; yet there are certain expressions against which we feel bound to wage war. The phrases "who it belonged to," "it might result in exactly the opposite of the user's intention taking place," "to stand steadily to their ground," are not elegant, while the word "contraption" is new to us. Is it straight from Indra's book, and untranslatable? The pleasantly vague word "infinite" is rather too plentifully scattered over the whole book, and it seems misleading to say "Tantalus himself could not have devised anything more irritating." Tantalus, poor fellow, was the last person to devise things irritating; it was the gods who devised the irritating fruits and water for Tantalus, because he revealed their secrets. But we do not wish to be captious. "The People of the Moon" presents, in a most alluring manner, some of the problems that Science hopes to solve in the future, and for many a schoolboy the book will throw a new light over those she has already solved.

We cannot finish without giving one instance of Oolaâlan ethics, of which we think most earthly editors would disapprove. "On gaining the main road at a point only a few yards from the Post Office the men espied a bevy of newsboys running towards them. . . The boys carried news rolls . . slung . . around their necks, . . and they displayed large scrolls announcing . . the chief items of the day's news. Indra and the inventor watched the little group, . . and when they were near enough to them, eagerly cast their eyes over the contents scrolls which the boys displayed." But Indra and the inventor did not *buy* a news roll.

Kalendar fur Elektrotechniker. 1896. Thirteenth edition. Edited by F. Uppenborn. (R. Oldenburg, Munich and Leipzic.)

The 1896 edition of this well-known annual pocket-book shows additions in the chapters on photometry, lighting and mechanical engineering. There is an entirely new article on Dr. Kallmann's method of fault finding in town-[illegible] circuits.

THE CROMPTON POTENTIOMETER: ITS USE AND CAPABILITIES.—I.

BY W. C. FISHER.

The recent universal adoption by central-station engineers and others of the potentiometer system marks the commencement of a new era in electrical measurement, an era which the engineer, as apart from the scientist, has sadly wanted—namely, an instrument capable of accurately comparing with some acknowledged standard any unknown current, E.M.F., or resistance, such an instrument to be capable of universal use, of infinite range and extreme simplicity, involving no calculations as to results or correction for temperature error, resistance of leads, &c. Judging by the general adoption, this want seems to have been met by the Crompton form of potentiometer; for, whilst there are other forms in the market, they do not seem to have been studied and worked out to such a complete state, due possibly either to want of faith in the system or an inadequate knowledge of the requirements of engineers at large.

As beyond a general description of the instrument in question, published in your columns in May, 1893, Vol. XXXI., p. 32, there exists no printed matter on the subject, it is to be hoped that the following notes and suggestions upon the working and capabilities of this special type of instrument may be of some assistance to those whose lot it may be to have such an instrument under their charge.

Originally suggested by Prof. Fleming to Mr. Crompton as a commercial or workshop method, it has from its first cumbrous form by successive stages been worked up to what might fairly be described as a scientific instrument of no mean calibre, an instrument by means of which electrical measurements from the lowest to the highest value may be taken by direct comparison with the official Board of Trade standard, certainly to well within $\frac{1}{10}$th per cent. under ordinary circumstances, whilst by special care a far higher degree of accuracy may be attained.

Describing the instrument as briefly as possible, it might be said to consist in its present form of 15 sections of wire connected in series, 14 of which are in the form of coils concealed in the instrument, the 15th being stretched along a scale suitably divided; each are accurately adjusted with each other, so that with a fixed E.M.F. of 1·5 volts over the whole each section has a fall of $\frac{1}{10}$th of a volt, the scale beneath the slide wire being divided into 1,000 parts, each part corresponds to $\frac{1}{10000}$th of a volt (*see* Fig. 1).

The unknown quantity x to be measured is placed in series with a galvanometer G and attached to the movable contacts A and B, the intermediate reading between the contacts or main sections of A being obtained by the movement of B along the slide or scale wire, x being so connected up that its E.M.F. opposes that of the main circuit. No deflection of the galvanometer takes place when the point of balance between the

Digitized by Google

opposing E.M.F.'s is obtained; such position, supposing it to exist in the diagram given, would be represented by the contacts 4 and 500 divisions of the scale wire, which, taking into account that each section is equal to $\frac{1}{10}$th of a volt, is equal to 0·450 volt. This represents the ordinary working conditions of the main instrument when used in measuring E.M F. or current. Under certain circumstances, more especially when measuring resistances, it is advisable to alter the main E.M.F., in which case the values of the sections are correspondingly altered; such conditions will be described as they arise in the study of the capabilities of the instrument.

Although the above represents roughly the diagram of the main instrument, there are fitted in it certain switches and a rheostat for adding resistance in the main current, so reducing the E.M.F. of the secondary cell ordinarily used to the proper value, and for connecting any series of x into circuit in due

so that measurements may rapidly be taken in ne[illegible]eter and a due array of necessary terminals, the true or[illegible]m of the instrument therefore being that shown in Fig. 2.

In using the instrument for the measurement of power, the first operation necessary is its due calibration—*i.e.*, the adjustment of 1·5 volts at the terminals of the whole of the sections; as shown in the diagram, a secondary is used as the source [illegible]ain E.M.F., and having, roughly speaking, an E.M.F. of [illegible]lts, resistance has to be inserted in circuit to bring it [illegible] to the 1·5 volts required. This value is ascertained by [illegible]stituting for x a known value or standard—*i.e.*, a Clark's standard cell; its temperature is noted, and the two points A and B are placed upon the figures corresponding to the value of the cell at that temperature, which we will suppose to be, in

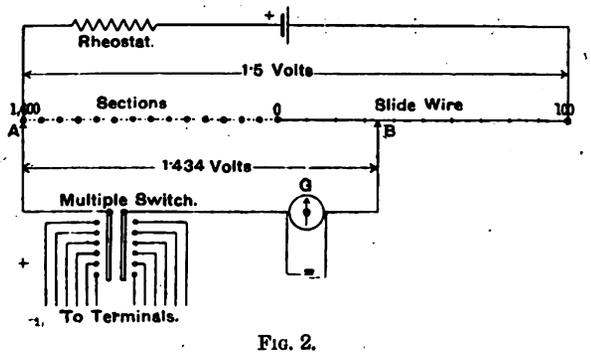

Fig. 2.

the case of Fig. 2, as 1·434 (in which it is seen that the contacts A and B are at 14 and 34 respectively), that being the certified value by the Board of Trade in volts of the standard cell at 15°C. Resistance is added in main circuit until there is no deflection of the galvanometer, due to the fact of the two E.M.F.'s—that in the main and galvanometer circuits—equalling one another; the instrument is thus standardised from what afterwards becomes the x circuit, and is then ready for working and obtaining the value of unknown E.M.F.'s. The act of switching *in* the unknown puts the standard cell *out* of circuit, so that no possible accident can happen to it, and it need only be brought into circuit again for occasional check purposes.

It will be noticed that the maximum observed E.M.F. on the potentiometer is 1·5 volts; all values therefore to be measured must fall within that range. To meet this requirement multiples and submultiples of the ohm are used, and are so proportioned that their maximum carrying capacity is some definite value proportional to that of the instrument, and it is entirely upon them that the range of the set of apparatus depends, the maximum standards made up to the present being for the measurement of 10,000 amperes on the one hand, and 3,000 volts upon the other, but this does not in any way suggest the limit, which might almost be described, in the case of current, as illimitable, whilst with voltage the question of insulation alone steps in.

Current Measurement.

Taking, first, the question of the measurement of current, this is done by passing the current to be measured through a standard low resistance (Fig. 3) of such value that the fall in volts with maximum current over the whole does not exceed that measurable on the potentiometer. The usual units adopted by the majority of the English central stations allow of standards for maximum currents of 1,500, 750, 150, 15 and 1·5—the last three for meter and lamp testing, the preceding two for machine and instrument tests. To be effectively used with the instrument described they should be so proportioned as to be direct reading—that is to say, the first, with a load of 1,500 amperes, should allow of a fall of 1·5 volts. Each section of the instrument having $\frac{1}{10}$th of a volt, will therefore correspond to 100 amperes, each division on the scale to 0·1 of an ampere; the second standard should be similarly proportioned, 750 amperes reading at 0·750 volt; the third standard, for 150 amperes, should have 10 amperes per section and 0·01 per division of scale; the fourth, for 15 amperes, having 1 ampere per section and 0·001 per division; the fifth, for 1·5 amperes, having 0·1 per section and 0·0001 per division. If, therefore, any of these standards are placed

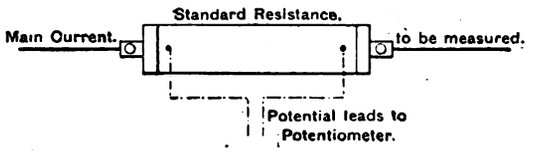

Fig. 3.

in the circuit, current through which is to be measured, the fall of E.M.F. over same is balanced on the potentiometer, and value in current read off accordingly direct. For economy in material or weight, when standards are carried about, it is customary in some instances to adopt half values—that is to say, the standard for 1,500 amperes would be half the resistance of that already described, the consequent E.M.F. would be halved, and the value would be read at 750 on the instrument corresponding with the fall of volts over standard with full load; other values would be in similar proportion, and all would need to be multiplied by 2 to obtain true values. This, however, whilst giving economy in material, or a standard having twice the carrying capacity of the former, is not to be recommended, as, when introduced with other standards having no multiplier, errors arise and quick reading becomes impossible. Recently the question of weight and economy of space, &c., has been overcome by the design of standards of tubular form artificially cooled by the circulation of water and very heavy connections. In this manner a current density of from 25 to 30,000 amperes per square inch is possible, which allows of a very compact standard being constructed. However, this will be treated separately when the construction of such standards is considered. It is, however, interesting to note in connection with these standards that no danger is to be anticipated in connecting them to the ordinary supply, as a moderate length of ordinary hose pipe amounts to practical insulation. In fact 30ft. of ordinary three-ply rubber tubing, $\frac{3}{4}$in. bore, supplied by the Silvertown Company, filled with ordinary "commercial London water," and practically armoured by being laid its whole length along a lead floor, had, when tested from end to end of the liquid with 100 volts, a resistance of one megohm.

To one not accustomed to the use of the different standards it is puzzling at times to give, off-hand, the value obtained.

Digitized by Google

Very little practice, however, is required, and a very simple guide to the memory is merely to note the value and maximum-carrying capacity. For instance,

$\frac{1}{1000}$th	ohm	1,000	amperes	at 1 volt,	or	1,500	amperes at 1·5 volts
$\frac{1}{100}$th	,,	100	,,	1 ,,		150	,, ,,
$\frac{1}{10}$th	,,	10	,,	1 ,,		15	,, ,,

Measurement of E.M.F.

The maximum E.M.F. ordinarily measurable on the potentiometer, as has been previously described, is 1·5 volts, but for secondary cell tests, &c. it may be made 3 volts by adding another secondary, and balancing with the Clark cell at half value, but in that and other cases in which it may be done it is necessary to multiply the reading by 2 to obtain the true result. When, however, some very much higher E.M.F. has to be measured, it is necessary to place it across a very high resistance, the fall over some portion of which only is measured (*see* Fig. 4). For instance, taking a box of 100,000 ohms, across which is placed 1,000 volts, the fall over 100 ohms corresponding to $\frac{1}{1000}$th of the total, and represented by 1 volt only, is carried to the potentiometer; in the same manner, if it be 100 volts, the fall over 1,000 ohms, or $\frac{1}{100}$th of the whole = 1 volt, is connected; or again, if 10 volts, that over 10,000 ohms, or $\frac{1}{10}$th of the total, still 1 volt only is taken to the instrument. The instrument is, therefore, direct reading, unless, as in the case of current measurement, half values are taken and the reading doubled—a practice equally bad in this case, and for the same reasons, therefore, to be avoided.

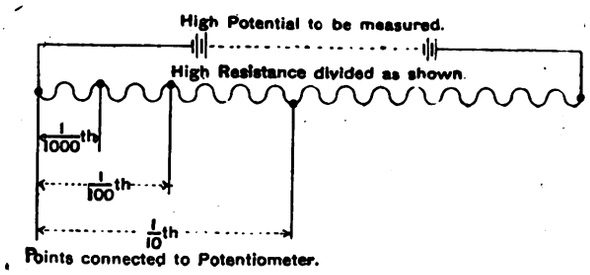

FIG. 4.

The true value to be assigned to the reading may be again somewhat puzzling to the unpractised, and is best got at by remembering or noting the terminals connected, if to the

highest	1,000	volt	reading wuold be	at 1 volt
next	100	,,	,,	,,
again	10	,,	,,	,,
or	1,500	reading	would be	at 1·5 volt
	150	,,	,,	,,
	15	,,	,,	,,

One point only remembered, and the rest is easy and no mistake is possible.

Measurement or Comparison of Resistances.

The measurement of resistances by the potentiometer method is a matter of great simplicity and accuracy, and has the great advantage that, as in the case of E.M.F. and current, results may be obtained direct without calculation.

In the standards supplied for current and E.M.F. measurement we have accurate submultiples of the ohm—*i.e.*, $\frac{1}{1000}$th, $\frac{1}{100}$th, $\frac{1}{10}$th of the ohm, and also multiples of 100, 1,000, 10,000, and 100,000 ohms, the missing 10 ohms to complete the series being easily obtainable with these. It is therefore possible to measure from the infinitesimal part of an ohm to many megohms, in the following manner: The unknown is placed in series with the standard with which it is to be compared (*see* Fig. 5); a current suitably adjusted is passed through both, the E.M.F. at the terminals of the standard being duly connected with x and balanced at any point most suitable on the instrument; the E.M.F. at the ends of the unknown is then brought into instrument circuit at x, and its value compared with that of the standard.

Whilst it is usual and best to balance the standard at a number corresponding to its value, and the value of the unknown is accordingly read off direct, it is not absolutely necessary that this should be done (more especially if the operator is an adept at the slide rule, in which case it is immaterial where the standard is balanced, as the unknown being in direct proportion its value is found at one setting). Very often it is more convenient to balance at some multiple of the standard, the value of the unknown being obtained by dividing the figure of its balance by the multiple adopted.

Taking an example, we will assume it is desired to measure a circuit of approximately 100 ohms; it is placed in series with the 100 ohms standard and a source of E.M.F., a pair of potential lines being run from each to the potentiometer, as shown in Fig. 5. We now have four methods of procedure open to us in balancing the standard:—

1. The points A and B are put at the figures representing the exact value, or some multiple of the standard, and the adjustable resistance in unknown circuit altered until balance is obtained.

2. A and B are put to any point where balance of the standard may be obtained.

Both these methods are advisable when the instrument is already adjusted for use with the Clark cell.

3. Balance of standard is obtained by adjustment of E.M.F. in main potentiometer circuit by means of the rheostat.

4. Balance of standard is obtained by adjustment of potentiometer and unknown circuits.

In the No. 1 case the balance of standard is effected, say, at 100 (A = 1, B = 0, or A = 0, B = 100), the potential of the unknown is brought into circuit and value obtained by movement of points A and B; this will correspond with the resistance, supposing it to be A = 1, B = 270. The resistance therefore is 127 ohms, being as 100 is to 127; if greater accuracy is required the

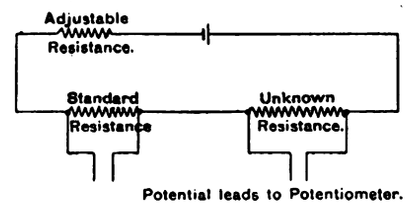

FIG. 5.

standard may be balanced A = 10, B = 0, in which we might get the unknown as A = 12, B = 753, or 127·53 ohms.

In No. 2 case, with the same resistances, the standard balanced at 325 (A = 3, B = 25), x would duly balance at 414 (A = 4, B = 14).

$$\therefore\ 325 : 100 :: 414 \text{ to } x, \text{ or } 127{\cdot}5 \text{ ohms.}$$

Cases Nos. 3 and 4 would be but a repetition of the above, as would also be the procedure if other standards were employed.

Conductivity Tests.

In conductivity tests the procedure is, of course, the same as that pursued in measurement of resistances. The sample strip, wire, cable, or sheet is placed in series with the standard considered most suitable, and its resistance ascertained as accurately as possible; this is duly compared with that calculated in the usual way, from its known length, section, weight, &c., and the percentage conductivity at given temperature ascertained. This, however, is not necessary, if comparison is made with a known copper standard, duly protected from atmospheric influences and injury, in which case the conductivity may be read off direct, which is very much more simple and occupies less time.

Thermometry.

Nothing has so deservedly called forth the attention of the scientific world and the thanks of those interested than the investigations into, and development of, the platinum thermometer by Messrs. Callendar and Griffiths. To anyone accustomed to the use of the ordinary thermometer, its sluggishness and vagaries—the difference between it and the platinum thermometer is as darkness to light; acting almost instantaneously, and with precision, true temperature readings by its means are obtained far more quickly and accurately, and at times under circumstances not attainable by the earlier method. To the measurement of temperatures by means of the platinum

Digitized by Google

thermometer the potentiometer lends itself well by reason of its flexibility and range, and the total disregard of resistance of leads and consequent compensation. Whether it be ordinary atmospheric changes of temperature, or those produced by friction or intense heat, from the melting point of ice to that of the platinum wire itself, all comes easily within the

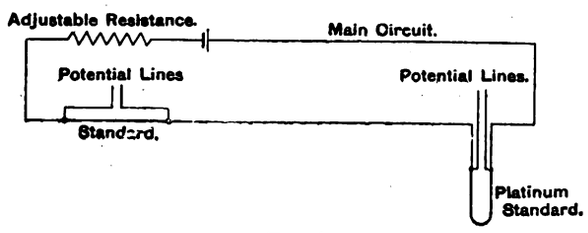

FIG. 6.

range of the instrument; therefore, by its means temperatures of liquids, flue gases, hot bearings and journals or of the atmosphere may easily be measured in the following manner, shown in Fig. 6, in which the platinum spiral is placed in series with a battery and standard resistance R (which may be simple, compound, or compensating) having a temperature coefficient known or practically negligible. This standard is equal in resistance to the pyrometer when at the temperature of melting ice; when, therefore, placed in circuit, as described, and balanced at any point of the potentiometer, any change in the resistance of the platinum spiral is at once detected by comparison, assuming it to be caused by temperature. Such temperature may be measured by means of the constant supplied with the thermometer, and which may be practically taken as 0·38 per cent. per degree Centigrade, which, divided into the difference between the balance of standard and spiral, gives the actual temperature in degrees Centigrade.

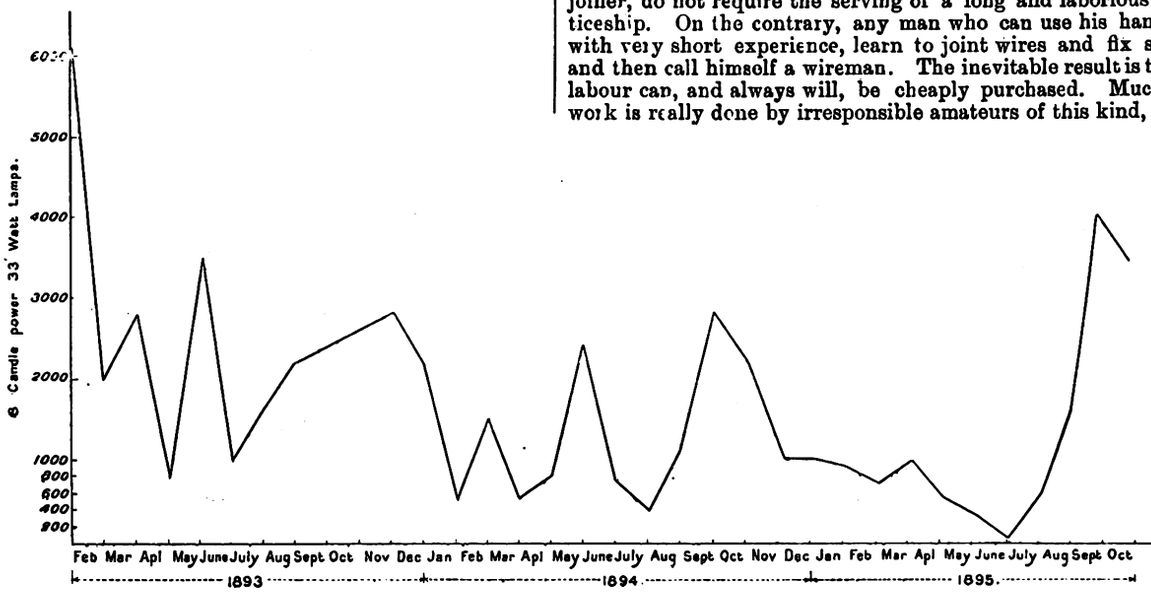
As an instance, we will assume the standard as balanced at 10 on the slide wire of potentiometer, and upon switching in the potential at the terminals of the platinum spiral we find it represented by 13·8 on the slide wire. The difference in the two readings divided by the above constant gives the temperature as 100°C.; if the balance of the platinum spiral had been at 138 the corresponding temperature would be 1,000°C.

Of course it is easily seen that the scale of the thermometer, as indicated by the potentiometer, may be made anything that is convenient; as indicated above it is somewhat contracted, but by balancing the standard at 100, instead of 10, we increase it tenfold, the maximum reading being 1,500, corresponding to 1,315°C., or 1,000°C. being indicated at 1,380.

CONCENTRIC WIRING.*

BY SAM. MAVOR.

Considering the importance of the subject of electric light wiring, it does not seem to have had an adequate share of the attention of this Institution. This is the more unfortunate as the tendency now is to allow the business of wiring to drift out of the hands of experienced electrical engineers into the hands of the legion of plumbers, gasfitters, and others who, often with small claim to the title, write "Electrical Engineer" upon their signboards. It is inevitable that wiring shall fall more and more into the hands of tradesmen of this class. They will follow more or less closely the methods of their predecessors, and defects in existing practice will thus be widely propagated. This is a question which seriously affects the whole industry, and hence the importance of this Institution setting an example by aiming at and endeavouring to secure a high standard of excellence in wiring work. It is a characteristic of the business of electric light wiring that it is peculiarly liable to the risks attending bad workmanship. Internal wiring—that is, the laying of insulated conductors in grooved wood casings, the jointing of these conductors, and the fixing of switches, fuses, &c.—is a comparatively simple matter. Apart from the distribution of lights and arranging the circuits and their routes, it is not work which must necessarily be done by a highly-trained and skilled tradesman. For such work as the mason's, the bricklayer's, the joiner's, cabinetmaker's, &c., a man requires the training of a long apprenticeship, which entitles him to the wages of a skilled craftsman; but the mere laying of wires already manufactured in grooved wood casings erected by a joiner, and fixing ready-made switches on bases also prepared by the joiner, do not require the serving of a long and laborious apprenticeship. On the contrary, any man who can use his hands may, with very short experience, learn to joint wires and fix switches, and then call himself a wireman. The inevitable result is that such labour can, and always will, be cheaply purchased. Much wiring work is really done by irresponsible amateurs of this kind, who are ignorant of the consequences which might result from their carelessness or lack of experience.



Curve showing the number of Lamps connected to the Electric Supply Mains of the Glasgow Corporation during each month from February, 1893, to October, 1895, inclusive.

A further reason why electric light wiring is often not carried out by first-class labour lies in the intermittent nature of the employment. There are certain seasons of the year when the wiring contractor has little of such work, and must then discharge men. Indeed, wiremen are many times taken on at the beginning of a job and paid off at the end of it. Workmen of skill and intelligence soon find this out, and they seek employment in branches of the business where their qualifications find a better and more steady market. We all know how demoralising it is for men to be idle for months at a time, and how apt they are to drift into lazy and careless habits. The diagram showing the number of 8 c.p. lamps connected to the Glasgow Corporation mains during each month from January, 1893, till the present time illustrates the fluctuations in the demand for wiring. You cannot expect a man to have a thorough interest and

* Paper read before the Institution of Electrical Engineers, November 28th.

Digitized by Google

sense of responsibility in his work who knows that he will be paid off at the completion of the job. As wiring jobs often last only a few weeks, the poor wireman may have been in the employment of half-a-dozen masters in the course of a season, with intervals of enforced idleness. In the case of joiners and plumbers and kindred trades, when outside work is slack, the men may be employed in the shop at preparing material or in manufacturing; but not so with the wireman. The material is all already prepared for him by skilled hands—his business is only to erect it. The larger firms who have a variety of electrical work can find employment for the best of their wiremen in other branches when internal wiring is dull. But they, too, when business is brisk, have to fall back upon the shiftless creatures who often present themselves as "wiremen." The proportion of "improvers" and apprentices employed at wiring is very much larger than in any similar trade.

The business—if it may be called a business—of electric light wiring has thus several features peculiar to it making for unreliable workmanship, which, in the absence of competent supervision and careful inspection, lead to defective work and resulting fire risk.

The plumber's and the gasfitter's work are to a great extent self-testing. If a water pipe leaks we see the water, and if a gas pipe leaks we usually smell the gas; but we have no sense—no physiological sense—to enable us to find hidden defects in our electric wiring. A building may be wired in the most dangerously slipshod style, yet the lamps may for years burn none the less brightly, until the latent faults have opportunity to discover themselves.

Insulation tests after the completion of the work, if in dry and well-seasoned buildings, are of little value. The insulation tests of the wiring of an old building might show results three or four times higher than the most stringent rules require, and yet there might be a score of dangerous defects only awaiting opportunity to develop. No tests can be applied for the detection of these defects after the work is completed and covered in. On the other hand, in a new and damp building the insulation might be far below the requirements of the rules, and yet be absolutely safe. The important thing is that the work shall be carried out in such a style that the insulation attained shall be permanent, and tend to increase, rather than decrease, with time. Wiring has to be carried out in situations so different, and must comply with conditions so varied, that it is impossible to formulate rules which can in all cases be adhered to. Modifications must be allowed to meet special requirements, and the extent of these must be left to a great extent to the discretion of the contractor. That such discretion ranges over very wide latitudes is indicated by the large discrepancies between the tenders of different contractors for the same wiring work. When the prices of experienced contractors estimating for wiring work to a carefully drawn-up specification vary as we know they do, it is not strange that inexperienced contractors tendering in the absence of a specification, and without the prospect of any supervision, should quote prices which would not purchase suitable materials alone. These are matters of primary importance to the fire insurance companies, and they are much too lax in looking to their interests in this regard. Bad work is being carried out every day, and the insurance companies are complacently taking the risk. Several offices have issued wiring rules, and it is a very good thing for them to have rules; but what is the use of rules if they are not enforced? At present they are really only recommendations, and anyone who is so inclined may evade or ignore them. It is common knowledge that this is constantly done.

The present procedure of the insurance companies is most ingenuous. They send a schedule to the contractor who is carrying out the work—or, rather, who has done the work, for it generally arrives after the job is completed—and they then request the contractor to oblige them by giving replies to a list of questions. They receive the document filled up by the contractor, who has no responsibility beyond a moral one, and file it away, and presumably are satisfied that the thing is all right. They thereby exhibit a trust in human nature very flattering to the wiring contractor, but of the wisdom of which some of us may have our doubts. Until the insurance companies have organised a thorough system of inspection they will not have taken the steps necessary for their own protection. It seems to me that in every considerable town there ought to be a permanent official (in the pay of the fire offices collectively) whose duty it would be to inspect all electric light wiring while in course of erection, and to ruthlessly condemn defective workmanship or material. If such a staff of well-chosen, reliable and sufficiently well-paid inspectors were scattered over the country, they would soon put a stop to jerry work. The moral influence of their presence in the town would be a wholesome check upon the cheap-jack. The cost when spread over all the companies would be trifling, and would be amply repaid by the reduction of fire risk. The insurance companies already have one man in their collective employment in each of several of the larger cities. This man is an *attaché* of the Salvage Corps, and his duties are confined to the warehouse district. His functions are to familiarise himself with the positions of main switches, fuses, and cables, &c., in the warehouses with a view to his being of service to the Fire Brigade in case of emergency.

Before leaving this subject it may be noted that Lloyd's Register of Shipping some years ago issued a set of recommendations for the guidance of shipbuilders and owners in fitting electric light on their vessels; but, as they took no steps to ensure that effect was given to their suggestions, these remained a dead letter. The large number of electric fires on board ship during recent years, chiefly due to inferior work resulting from the practice of accepting the lowest tender, has impressed upon Lloyd's the imperative necessity for supervision. They have, therefore, issued a new set of rules, and they are now arranging for such a system of inspection as will ensure these rules being followed. The fire insurance companies would do well to profit by the dearly-bought experience of Lloyd's. If they do not, they will assuredly have to learn the lesson at their own expense. Although the insurance companies are primarily interested in this question of fire risk, the matter has a direct and important bearing upon the electric lighting industry. We must all recognise the desirableness of ensuring that wiring shall be carried out in a style which shall be fire-proof, electrically and mechanically good and durable, and shall not be offensive to the eye.

There is a steadily growing dissatisfaction with the generally adopted practice of enclosing the conductors in wood casings, and a steadily growing conviction that something better might be done. In most factories and warehouses it is possible to have the casings laid upon the surface, but in dwelling-houses or in good hotels or clubs it should not be tolerated. Everyone is familiar with the unsightly wood casings and clumsy crockery ware which disfigure so many of the best hotels and other buildings in this country. How often we hear that electric light is not adopted because of the dread of the wood casings, and the cutting about and disturbance which their erection involves! Those casings are a standing reproach to the people who erect them. One has only to see the interior of a good building which a contractor has dared to wire on the prescribed lines with wood casing to realise how utterly unsatisfactory is the system. Those hideous casings are entirely out of harmony with their surroundings, and offend the eye at every turn. They blunder across ceilings and cornices, intrude upon decorative panels, and push their ruthless way through frieze and dado; while out of sight beneath the floors the joists are cut away to clear the casings until the margin of strength is often perilously low. The truth of the matter—and we all know it—is that we cannot carry out the wiring of, for example, a private residence in compliance with the recognised rules for double wiring and wood casing without excessive cutting of floors and plaster work, and disfigurement of walls and ceilings. At every turn we have to compromise between the decorations of the house and the fire insurance rules, and the concessions must needs be generally in favour of the decorations. In short, the modifications of the rules require to be so many and important that this system of wood casing is one which cannot be consistently and thoroughly carried out.

When the usual double wiring is carried out in situations where moisture charged with acid from cemented or plastered walls of interiors, or in such buildings as paper mills, wet spinning mills, dye houses, breweries, distilleries, chemical works, and the like, the destruction of the insulation is only a matter of time, and the casing, by harbouring the moisture around the conductors, hastens the process. After the insulation has broken down, electrolysis, assisted by the acidulated moisture, takes place, and deposits away the copper of one of the conductors, with the consequent risk of heating and ultimately of sparking. The presence of moisture being a necessary condition of the development of such faults, the dampness of the surroundings of the conductors greatly reduces the danger of fire, but that the risk is not absent is proved by the charred and burned casing or woodwork found at such places. It must be remembered, however, that heating due to diminished section of the conductor may occur at a time when the moisture which caused the fault has disappeared, and this is a danger which no amount of fuses will modify. How can you ensure that your wood-cased conductors shall never be subjected to such conditions? And how many of your average wireman's joints would stand 24 hours' immersion in water or soaking in moisture? The miserably futile expedient of attempting to waterproof the casings with putty and varnish is sometimes resorted to; such makeshifts are too childish. Lead-covered conductors are occasionally used where much moisture has to be encountered. But these for double wiring are a mistake, unless the positive and negative wires are both enclosed in the same lead sheathing. The objection to separate lead-covered conductors is that, if there should be an earth or leak on the negative wire, and the lead and insulation of the positive wire becomes punctured at a damp situation, the lead becomes charged positively, and will be deposited away over its whole length where moisture is present to assist electrolysis. This remark has no application to lead-covered conductors on board ship, where the lead sheathing is

Digitized by Google

throughout in intimate contact with the hull of the ship, nor to lead-covered concentric conductors. This liability to injury from moisture is the fatal weakness of the ordinary wood-cased system. It is of much greater consequence to obtain a moderately high insulation, which may be relied upon to be durable, than to have—as can easily be had in a dry building—an insulation resistance of many megohms, which will disappear on the approach of the char-woman and her wash-bucket, or is at the mercy of the first loose slate or leaky water pipe. What a common experience it is to discover wiring faults in the fungus-grown casings in damp and mouldy basements, or upon the "sweating" surfaces of cemented walls or ceilings! A fault which developed a few weeks ago in the writer's office is a good illustration of the weakness of the present double-wiring practice. The walls are covered with a light-green paper, which on one side of the room is pasted to a wooden partition, and through this partition and paper the conductors are led to a switch. Behind the base of this switch sparking was observed. On examination it was found that in our humid climate the paper had absorbed moisture from the atmosphere, and this moisture, charged with an acid held in the paper, had attacked and destroyed, first the insulation of the conductors, and then the copper, until of the latter only a green sulphate remained, and the circuit was interrupted. As only one lamp was in circuit the spark was small and the heating effect slight, but under other conditions the results might have been serious. This is an interesting example of a fault developing in an apparently dry and well-aired and warmed room, and under the eyes of one whose business it is to avoid such faults, and to whom a spark was the first intimation of anything being wrong.

After wood casing, with its perviousness to moisture and other attendant disadvantages, the biggest blot on existing practice is the indiscriminate use of fuses. Some insurance people, and wiring contractors too, imagine that the risk of fire varies inversely as the number of fuses. The contrary is more near the truth. Fuses are not only a nuisance, they are apt to be a positive source of danger. The smaller number of fuses used the better; but they must be absolutely reliable, well mounted, and well placed. Most of the leading wiring contractors have adopted the distributing box plan of wiring, in which the branch fuses are grouped at the distributing centres. This system should now be compulsory. The use of isolated fuses should be strictly prohibited. The only inducement to use them is a trifling saving in the cost of conductors. The number of fuses should be kept down by keeping up the section of conductors. The larger expenditure on branch conductors entailed is amply repaid by the simplicity and uniformity secured. The dangers of diminishing the section of conductors and scattering fuses through a building are that the crockery fuse bases and cases are liable to breakage; the terminal screws are liable to become loose and so cause heating; and last, but most important, the danger of a conductor of too large area being used by an inexperienced or careless person instead of a *bonâ-fide* fuse, in which case the "fuse" is a delusion. This last danger is so real and so imminent that the insurance companies ought long ago to have prohibited the use of such fuses. The writer was recently in competition with a firm of contractors of large experience who do a great amount of wiring, and were in this case estimating for wiring about 200 lamps of 16 c.p. each. Samples of the conductors, &c., quoted for were invited along with the estimates, and our double-wiring friends submitted a sample of each of the *nine* sizes of insulated cables and wires, with their corresponding wood casings, and of each of the several sizes of fuses which they proposed to use. Nine different sizes of cables and wires were certainly not essential to the double wiring of this building, but they were part of the method of a much-experienced contractor, and his method is common to many others.

Switches have been greatly improved during the last few years, both in mechanical design and in external form. The clumsy switches, with the ugliness of their porcelain covers embellished by gilt lines or floral decorations, have now nearly disappeared. They are superseded by switches of neat appearance, with suitable metal covers. The working parts of the switches are of a much more mechanical type than formerly, but there still remains ample room for improvement. There are far too many parts, too many screws, and too many contacts. The practice of dispensing with binding screws and soldering the wires directly to the contact plates should be highly commended. How often one sees the attempt made to secure the ends of conductors—frequently of considerable size—under paltry little cheese- or round-headed screws and washers absurdly too light and inadequate to the purpose! The ceiling rose is also a weak spot in double wiring. There are far too many contacts in it. To begin with, there is the usual crockery base, and upon this base are three little brass plates, with twice that number of brass screws. Each of these six little screws binds to a contact the end of a conductor or fuse, and every screw of them is liable to become loose, and every contact to become oxidised. Where vibration or moisture are present the development of trouble is only a question of time. Do those who so freely erect these little collections of screws and contacts ever consider the harvest of petty troubles and annoyances which will be reaped by-and-by?

We must now pursue our painful path of adverse criticism to the lamp holder. The double-contact lamp holder, especially when attached to flexible pendants, is the frequent seat of short-circuit and minor troubles. In this little piece of apparatus there are two contact plates, carrying the buffer springs and the inevitable binding screws. Each of these contact plates must be insulated from the other, and both from the surrounding metal tube. When this is done small space remains for further intrusion. But the flexible conductors are still to be brought in and pinched under the binding screws. Stray strands from these flexibles, where they are not most carefully soldered, are frequently responsible for short-circuits and the melting of many fuses. The risk would be reduced if here also binding screws were dispensed with and the wires brought straight through the insulating disc into holes in the plates and soldered therein.

It is with a sense of relief that one turns from double wiring and all its attendant ills to the simple mechanical and straightforward methods of concentric wiring with an uninsulated outer conductor. So far as the writer is aware, no system of concentric wiring in which both the inner and outer conductors are insulated has ever been used for indoor work. It appears probable that the difficulties in the way of designing junctions, switches, and other accessories which shall meet the electrical and mechanical requirements within moderate dimensions and at reasonable cost, will prevent the introduction of such a system. Two and three-wire concentric cables with each conductor insulated are largely used as mains in connection with two and three-wire systems, but in such cases there is no difficulty in providing junction boxes of adequate size. The only system of concentric wiring which has been adopted for internal use has an uninsulated outer conductor, and it is this system that is known as "Concentric Wiring." It is important that it be clearly understood that concentric wiring is not "single wiring," but is something essentially different. This distinction between concentric wiring and single wiring is necessary, because the two have been frequently confused. No method of wiring merits the title "concentric" which is not consistently concentric throughout. In a concentric system the central conductor must be everywhere surrounded over its insulation by a metallic sheathing of conductivity equal to or greater than the core. The switches and fuses should be in the central wire and enclosed in metal cases. These cases or boxes should be electrically and mechanically jointed to the outer conductor, and so form part of the continuous metallic envelope in which the central conductor is enclosed.

It must be pointed out here that, under the existing Board of Trade regulations referring to the insulation of electric light supply mains, concentric wiring is not admissible where connection has to be made to a source of public supply in this country. This is a matter to which we shall recur, and shall meanwhile consider the question of concentric wiring with regard to installations supplied with current from independent plants. The adoption of concentric wiring is the royal road out of the difficulties and dangers which beset double wiring. It seems to be difficult for those who have been accustomed to devote so much pains to attain good insulation of both conductors to realise that there is no necessity for doing so. The adoption of concentric wiring dispenses with this necessity, and abolishes risks which make a high standard of insulation of both conductors in a two-wire system so desirable. Much misunderstanding and prejudice, due to lack of information, exist with regard to concentric wiring; but there is complete absence of valid objections to its use, and prejudice against it is soon dissolved by an acquaintance with the system.

Some of the fire insurance companies were at one time rather suspicious of concentric wiring, probably because they feared its adoption would lead to the abolishing of their cherished rules regarding the width of fillets in wood casing, &c. The insurance companies are, however, now unanimous in their favourable verdict on the subject, and have recognised the advantages of concentric wiring from their point of view. More extended experience and appreciation of its fireproof qualities must confirm the preference many of them now have for concentric wiring.

It has been stated that, owing to one conductor being already earthed, the liability to complete breakdown of the insulation is doubled. This might be true of double wiring, but is certainly not true of concentric. The outer conductor being already at earth potential, there cannot be any risk whatever of shock or spark being experienced from it. There is thus only one vulnerable conductor, and this, with its insulation, being encased throughout its entire length in the metallic sheathing formed by the outer conductor, is well protected against injury. The consequences of injury to concentric and to double wiring are essentially different. In the case of the concentric conductor, if it should be crushed or a nail be driven into it, the instantaneous result is a dead short-circuit and the melting of the fuse. If the insulation should be punctured and moisture gain access, the distance across the insula-

Digitized by Google

tion between the conductors is so small that the fault immediately develops into a short-circuit, and the spark passes from the centre conductor to the inner surface of the metallic sheathing, and being entirely within the sheathing it cannot communicate fire to its surroundings. Concentric conductors are thus self-testing. Faults cannot endure. They cut themselves out automatically. Or, rather, this is what they would do if faults were experienced; but we never have faults in lead-covered concentric conductors. How different is the case of ordinary double-wire conductors laid in the separate grooves of a wood casing! The casing which is provided for mechanical protection may become a positive source of danger, and may be ignited by leakage across the fillet—a danger which the fuse is powerless to prevent. In concentric wiring there is only one cable to handle instead of two, and this carrying its own protection the necessity for wood casing is abolished.

Perhaps the most conspicuous advantage of concentric wiring is that it may be so easily and so effectually made waterproof. The cables may be enclosed in lead sheathing laid under or over the outer conductor, and hermetically sealed to the various apparatus into which the cables are led. This must appeal to all those who have had a varied experience of wiring. If moisture—the arch enemy of good insulation—can be permanently excluded, it means the permanent maintenance of a high standard of insulation, and consequent freedom from trouble.

The next important advantage to be claimed is the large reduction in the number of fuses. The drastic method of abolishing fuses is to maintain the section of the conductors. This can readily be done in concentric wiring to an extent impracticable in double wiring. Conductors of much larger section may be conveniently and safely led into C.C. lampholders, ceiling roses, and wall sockets, than is possible in double wiring. And thus, by maintaining the section of conductors right into the lamp holders, many of the objectionable fuses are abolished. The fuses when reduced in number are more easily centralised and arranged in groups of standard size. It may be objected that if the number of fuses is diminished a larger number of lamps are affected in the event of a fuse being melted by a short-circuit. This is a very natural objection for one experienced in double wiring to offer. But it has no application to concentric wiring. We never have short-circuits. It is in double-contact lamp holders, and double-wire flexibles, ceiling roses, and the like, that short-circuits occur. Compare a central contact and a double-contact lamp holder. A 7/16 concentric cable may be led into the former more easily, and with greater safety, than two single No. 16 L.S.G. wires or their equivalent can be led into the latter. It is not necessary to lead 7/16 cables into concentric lamp holders, but the possibility suggests the large margin of safety in favour of the C.C. holders. The difficulty of avoiding mishaps in double-wire lamp holders will be emphasised by the introduction of 200-volt lamps. While on the subject of lamp holders, it may be noted that, there being only one buffer spring in the C.C. lamp holder, and that exactly in the centre, there is less risk of twisting lamps out of their collars while inserting or removing them. Concentric lamp holders, ceiling roses, and such fittings, having only one—and that a central—contact to be insulated, may be made of better mechanical design than where within the same space two contacts have to be insulated, each from the other, and both from the containing case. The benefit of the great reduction in the number of parts can hardly be exaggerated, the liability to derangement is so very greatly reduced.

In regard to fittings, the comparison is again in favour of concentric wiring. The flexible conductors of which the pendants are made are of such large section that they are mechanically strong. The pendant terminates at either end in a screwed brass nipple with insulating plug and central contact—an arrangement which is substantial without being clumsy. No loose strands are possible. The top nipple of the pendant is screwed into the junction or fitting base, and the nipple at the lower end is screwed into the lamp holder. The brackets are similarly wired to screwed nipples with central contacts. The erection of fittings is therefore an extremely simple operation, and the labour so employed is reduced to a minimum.

The method of concentric wiring is based upon a full recognition of the fact that electric light wiring, in order to be permanently durable and reliable, must be impervious to moisture. So far as the writer is aware, this is the only method of wiring which provides a continuously waterproof metallic sheathing over the insulation from the main switchboard to the lamp holders. The main switchboard has the usual single-pole switch and fuse arrangement, and the board is surrounded by the negative omnibus bar, which receives in sockets attached to it the outer conductors and sheathings of the concentric cables. The main cables—which are lead-sheathed throughout, and are generally armoured with galvanised iron wires laid over the lead on a cushion of jute—are carried without break or joint direct to their respective distributing boxes, where the central conductors are soldered to the omnibus bars, and the outer conductors terminate in gun-metal sockets secured to the boxes. The distributing boxes are of cast iron or cast brass, enamelled white inside, and fitted with fuses, or switches and fuses, as required. These boxes have close backs and hinged fronts closing upon an india-rubber ring, thus rendering them proof against dust or moisture. The concentric branch cables which radiate from these boxes are under all ordinary circumstances of uniform section, namely, 7/21½—equal in area to 0·005 sq. in. The outer conductor of the cable has the same section of copper as the core, and the whole is enclosed in a solid drawn tube of lead. Wherever a joint is to be made, or the cable led into a switch or fitting base, the centre wire is soldered to its contacts, and the outer conductor and its lead sheathing are received and terminate in a jointing pocket cast upon the switchbox or junction. The central wire and its insulation are thus enclosed throughout their length in a hermetically sealed metallic sheathing. The section of the branch conductor 0·005 sq. in. is carried into every switch and into every lamp-holder, no reduction being made. There is no necessity for any fuses other than those in the cast-iron fuse boxes. and these are all uniform and interchangeable. It is very rarely that occasion requires any departure from this plan. Many large installations have been carried out on the lines indicated, some of these amounting to several thousands of lamps, where only two sizes of fuses—main and branch, respectively uniform and interchangeable—have been used. The simplicity and reliability of such a system must be too obvious for emphasis.

The branch cables are led through buildings like flexible gas pipes, but they are not liable to damage as composition gas pipes are. The conductors and the insulation within the lead sheathing serve as a backing for the lead, so that it is not at all easily damaged. It has been the custom of the writer's firm for years to have their concentric conductors and joints embedded in the plaster of new buildings, and they have never known a single instance of a fault developing in conductors so treated. It is sometimes objected that where the conductors are so buried they are not accessible. They certainly are not. Why should they be? It is essential that wood casings carrying ordinary double wiring should be accessible; further, it is desirable that they should be visible wherever possible. But the conditions with regard to lead-covered concentric conductors are entirely different. Given a conductor and joint of imperishable materials, and impervious to moisture and the acids found in plaster and cement, and no reason remains for laying conductors on the surface, or for providing access to them where enclosed in plaster. This demand for accessibility, and the objection to cover conductors with plaster, is a relic of the times when india-rubber-covered conductors laid in wood casing were embedded in walls. The bitter experience which rapidly follows this practice results in the prejudice against covering any conductors with plaster. If anyone wishes to have his conductors laid on the surface of plastered walls, by all means let him do so, but there is no necessity either to lay them on the surface or to provide access to them where lead-covered concentric conductors are used. Access to the distributing boxes only is necessary.

Another bogey is the chance nail driven into the plaster. Consider how largely the practice of embedding composition gas pipes in plaster is in vogue, and how immeasurably greater is the danger resulting from the piercing of such a pipe than from piercing the insulation of a conductor. Yet how seldom one hears any objection to the practice! If a nail is driven into a concentric conductor the immediate result is an emphatic short-circuit, and the fuse melts; there is not the slightest danger. Two cases only of nails piercing embedded conductors have come under the writer's notice. Both of these were in the same building—a block wired for about 500 lights, where all the conductors were embedded in plaster. The faults—one behind a picture moulding, and the other behind a dado—were readily localised, and repaired before the work was completed.

The insulation resistance of the wiring in a new building is not a matter which causes any anxiety. The lead sheathings and brass junctions and switch boxes make one independent in this regard. In occupied buildings the lead-covered branch conductors may be led about under floors and behind plaster and linings with the greatest freedom and complete immunity from danger. The amount of lifting of flooring and disturbance to woodwork and plaster is only a fraction of that required for the carrying out of wood-cased double wiring. The junctions employed may be manipulated by any intelligent man who can use a soldering bolt. No careful lapping of insulating material around the joint is required. The insulation is air space, and there is none better. The branch conductors being of uniform size—so are the junctions—and men soon become expert in jointing. The operation is so very simple and easily performed that it may safely be done by unskilled labour. This feature specially adapts the system for export. As an illustration, it may be stated that a squad of Hindoos, chiefly tinsmiths, under the guidance of one European, carried out in the most satisfactory style the wiring for 3,000 lamps in 10 weeks. In mills or factories floored with wood the

Digitized by Google

conductors are cleated to the woodwork with brass cleats; and where iron beams and concrete floors are met, the conductors, with junctions (tapped to receive the pendants) attached at the proper intervals, are secured by brass or copper cleats to stranded steel suspending wires strained between eye-bolts attached to the walls. The laborious plugging of the concrete ceilings, with the resulting dust and disturbance to the work of the factory and expense to the wiring contractor, is entirely abolished. In single-storey weaving sheds, ironworks, or other buildings with iron roofs divided into bays, the same method of suspending the conductors between the beams or tie-rods is adopted.

In support of the claim that this method of wiring is reliably waterproof, the case of Messrs. Nobel's Explosives Company's West Quarter Factory may be cited. The buildings to be lighted are isolated and scattered over a large area in order to reduce the risk and minimise the effect of explosions. The regulations issued by the Home Office regarding electric lighting were so very stringent that it was impracticable to comply with them except by the use of concentric wiring. With concentric wiring everything was made easy. Its waterproof and fireproof properties overcame all the difficulties. Every joint and every yard of the conductors is outside and exposed to the weather, cleated for the most part to the gangways. The switches, of cast brass, and distributing boxes, of cast iron, are also all outside, protected only by watersheds. The work of wiring was completed more than three years ago, and, notwithstanding three years' exposure to the elements in this climate, the insulation resistance is as high as ever. Monthly tests of the insulation are required by the Home Office, and on the 10th of last month the insulation resistance was two and a-half times higher than the most stringent of the fire-office rules require for *indoor* wiring. In the nitrating department of the same factory, which is a quarter of a mile distant from the other installation, the insulation is equally satisfactory, although the wiring is subjected to the profuse fumes of nitric acid. It is noteworthy that the insulation of the wiring at both these places is not india-rubber, but is fibrous. The exclusion of moisture is therefore solely due to the lead sheathing and waterproof nature of the joints.

The more difficult the wiring of a building appears to be, the more favourable is the comparison to concentric wiring. The iron roofs, concrete floors, moisture, and other ills that vex the spirit of the double wirer, have no terrors for his concentric friend. For wiring in any situation, from collieries to boudoirs, where difficulties of erection have to be faced, or in situations where the conductors, &c., after erection must endure excessive heat or cold, moisture, acid vapour, or inflammable dust, concentric wiring meets the case. Conviction of its immense superiority is immediately impressed by inspection of buildings so wired. The thing requires to be seen to be appreciated. Concentric wiring had this further advantage—that a very simple and easily followed set of rules can be framed which are applicable to wiring to be carried out under widely differing conditions.

Contractors who are unacquainted with concentric wiring are often ready, when they know it is in competition with their double-wire tenders, to pour into the ears of their prospective client a dismal tale of the woes which would follow the adoption of any system which would not embrace their precious wood casing and crockery ware. If those contractors were informed on the subject, they would learn how great is their error. Take a contractor who has had experience of concentric wiring into any building whatever, and he will show how to make a better, more mechanical, reliable, and durable job, and generally at less cost, than is possible with double wiring. Those who have used only double wiring, and know no other, are reluctant, and with reason, to depart from practice in which their patterns are systematised and standardised, and in which their staff are trained. But when the change proposed is all in the direction of simplicity and reduction of labour the chief objections to its adoption are removed. That fires or minor troubles are not more frequent in badly-wired buildings is a fine testimonial to the safety of electric light wiring, but is no excuse for the continuance of slipshod work or adherence to existing methods where improvements are possible.

For mining work concentric wiring is specially adapted. The mechanical nature of the fittings, and the ease with which they and the conductors may be made waterproof, are important features. A concentric cable for mining purposes is more safe than two separate cables. A fall of material from the roof may rupture one of two conductors, and if current is passing the inevitable result is a spark at the point of parting. In fiery mines this might have serious consequences. With a concentric conductor, however, the fall would crush the outer conductor in upon the core, and so cause a dead short-circuit and melt the fuse before the cable parted. The spark would thus take place at the fuse at the pit bank. In the only case of such accident within the writer's experience the fuse promptly melted. Several devices have been proposed for the purpose of preventing a spark at the point of rupture of cables used in pit work. There is room for doubt as to the likelihood of these devices performing their functions in case of need. There can be no question that the concentric cable is much more simple, and it is probably more reliable than any of them. Further, none of these arrangements afford to the miner the immunity from personal danger from shock which the concentric cable does. An E.M.F. of 500 volts is frequently used for such work, and it is usually considered that such a pressure, although sufficient to give a disagreeable shock, is not dangerous to life. That this feeling of security is not well founded is unfortunately proved by recent fatal accidents. For power transmission in mines an ideally safe system is furnished by concentric cables with earthed sheathing, and switches, fuses, and other appliances enclosed in cast-iron cases, also earthed, and, if need be, enclosed-type motors with their casings earthed.

With regard to the wiring of ships, it is well known that an essential condition of durable wiring is that it shall be waterproof throughout. The British Admiralty for years tried all that the best materials of the usual double wiring sort, and most careful workmanship, could do to secure the desired result. But the incessantly recurring faults and derangements drove them six years ago to abandon wood casing and the ordinary rubber insulated conductors, and no longer to attempt the impossible. At the time indicated they discarded wood casing, and adopted in lead sheathing of the conductors the most effectual means of rendering them permanently waterproof. It was not, however, till four years later that they fully faced the question of making the wiring systematically waterproof throughout. Cast-brass distributing fuse-boxes, and cast-brass switch-boxes, all of waterproof patterns, were then adopted, and means taken to make watertight joints between these boxes and the lead conductors. The present patterns of distributing boxes, &c., although they serve their purpose, are still capable of improvement, and their awkward styles admirably illustrate the difficulty of designing waterproof fittings for use in a double-wire system, where the two sides of the circuit must be insulated from each other, and both from metal of the containing boxes. The Admiralty still adhere to double wiring owing to fancied danger of compass disturbance from concentric wiring. In the early days of electric lighting some of Her Majesty's ships were single-wired, and had dynamos of unsuitable types injudiciously placed. The results were compass disturbances. (The risks of compass disturbance, even from single wiring, are as nothing when compared with those which may arise from the dynamos.) The navigating officers naturally become alarmed, and the alarm has not yet subsided. That well-arranged concentric wiring has no effect whatever upon the compasses of a ship has been proved by the most careful tests. The waterproof qualities of concentric wiring and the safety from fire which it ensures peculiarly adapt it for use on board ship. The history of the development of electric light wiring in our Navy is highly interesting and instructive. The conditions to be endured by wiring on board ship are admittedly severe, but it is under these circumstances that the inherent defects in a system will be most rapidly disclosed. We may profit by the experience of the Admiralty, and accept their progress as an index to the direction in which wiring practice on shore should be improved. The same defects which led to the abandonment of double wiring in wood casing in the Navy exist in this system when applied to land work. The conditions on shore are less trying, and severe treatment less frequent, but the same inherent defects are there, and only await opportunity to develop.

And now with regard to possible electrolysis due to difference of potential along the outer conductor. In isolated installations where the distances are short the question of electrolysis may be dismissed as having no bearing. In cases where the distances are considerable the risk of electrolysis may be entirely avoided by adopting very simple precautions. The first of these—suggested to the writer by Mr. T. B. Murray—is to so proportion the conductivities of the inner and outer conductors that the fall in volts shall be nearly all in the inner conductor; the copper saved from the inner conductor being added to the outer in order to reduce to a minimum the difference of potential between its ends. Another method adopted by the writer is to provide between the outer conductor and its lead sheathing a very light insulation, and to earth the outer conductor only at the distant end. The layer of braiding laid for manufacturing reasons over the strands of the outer conductor before it is passed through the lead press is sufficient for the purpose, as the maximum difference of potential between the outer conductor and the lead is only a few volts.

The risk of electrolysis is greatly over-estimated. The prejudice against earthing the return conductor is largely due to the results of the early American practice of using an earth return for street railway circuits, instead of providing an adequate return conductor. The consequence of this habit was serious damage by electrolysis to gas and water mains. But what where the conditions? In many cases the current was put to earth at the distant points at 50 volts to 100 volts above the E.M.F. of the dynamo negative, and the large currents, amounting sometimes to thousands of amperes, which had to find their way to the earth plates at the

Digitized by Google

power house carried destruction in their path. But disappearance of these troubles has followed efficient bonding of the rails and the provision of complete metallic circuits of suitable conductivity—in other words, the substitution of a metallic *earthed* return for an *earth* return. In dealing with distribution for electric lighting purposes we do not have to contend with such large differences of potential at different points of the system, and the difficulties are not at all comparable with those encountered in street car work.

A three-wire system with the middle earthed, and concentric wiring on each side with the sheathing connected to the middle wire, is an ideally safe and reliable system of distribution. In a well-balanced three-wire system the fall of volts along the middle wire is negligible, and there is therefore no danger of electrolysis. No disturbance to telephones could take place. Stray currents passing between faults in the conductors would be impossible. The positive and negative conductors being each surrounded by an earthed sheathing, no current can escape from them. Leaks in concentric cables will not endure. The distance between the inner conductor and its sheathing being only the thickness of the insulation, a fault develops at once into a short-circuit which is internal to the sheathing of the cable, and the fuse at once comes into operation. But it must be repeated that faults are much less liable to occur in concentric cables than in double wiring. The importance and safety of the self-testing properties of concentric wiring must be obvious. As distributing networks are enlarged and extended, and the number of consumers increases, it becomes cumulatively more difficult to keep up the pretence of insulation. The present supposed insulation of the three wires is a sham, and the sooner we acknowledge it the better. Experience has proved that good insulation of all three conductors in an extensive network cannot be reliably maintained. Then why not face the difficulties, and end them by earthing the middle wire?

The initiation by Mr. Sidney Baynes of the use of 200-volt lamps and 400-volt distribution on the three-wire system has a significant bearing upon this question. That his policy from the supply engineer's point of view is a sound one is beyond doubt, and that it will be largely followed in the near future is certain. But what about the interior wiring? If the attempt is to be continued to maintain the insulation of all three wires, the possibility is introduced of having a difference of potential of 400 volts between one of the wires and earth. The danger from leakage across damp woodwork and the like is therefore much increased, and possible danger to life introduced.

Recent developments and experience demand the reconsideration of this question of earthing in its relation to electric light conductors. The Board of Trade have issued regulations referring to the use of uninsulated conductors for tramway and railway work. The time is ripe for the framing of regulations relating to an uninsulated middle wire in the three-wire system of distribution.

CORRESPONDENCE.

THE PRESIDENCY OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It is desirable that the present question as regards the presidency of the Institution should be thoroughly understood by all. The feeling that the President, head as he is of the electrical profession during his tenure of office, should be either a thoroughly representative practising engineer or an electrical scientist who by solid work has gained real pre-eminence, is of no recent origin. It has been much discussed amongst members both in London and in the provinces for several years past. Many members of the Council themselves entertain it, and if others were until recently unaware of its existence and strength, this is only an instance of how greatly some are out of touch with the sentiments of those whom they are supposed to represent.

Except under special circumstances, when, as is at present the case, some species of organisation is arranged beforehand, the election of officers is a purely nominal proceeding and must be so according to the manner in which nominations and voting are at present conducted. The Council are in name elected by the members and associates, but in reality by themselves. New members of Council, as also the higher officers, are nominated entirely by the Council, of whom a yearly increasing majority are perpetual past-presidents. The Council's nominations are kept secret until the ballot papers are actually issued, a few days only before the voting takes place. There is then no time for members to take any combined action, and mere disagreement with the Council's list can have no effect. The Council have created a custom whereby the senior vice-president is always nominated for the presidency, while the ordinary members have no real voice as to the initial election of the men who thus eventually step by a purely automatic process into the presidential chair.

Everyone must agree that the existing arrangements are highly unsatisfactory. The president of a scientific or engineering institution should be the choice not of a minority, nor even of a majority, but should be acceptable to the whole of the members.

Sir David Salomons has been put in a most unfortunate and unenviable position by the Council of the Institution. He will, I am sure, give those who are opposing his election to the presidency credit for entirely impersonal and disinterested motives. They have only the interests of the profession and of the Institution itself at heart. The sacrifice that he is asked to make is not inconsiderable in itself. By making it he will be rescuing the Council, to whose actions he owes his present difficulties, from what promises to be a serious fall. Be his decision, as also the eventual result of the election, what it may, it is clear that similar difficulties will occur again in the future unless radical changes in the whole machinery by means of which the Council and its officers are elected are immediately carried out.—Yours, &c., A. A. C. SWINTON.

66, Victoria-street, Westminster.

BEHAVIOUR OF TRANSFORMERS AT INSTANT OF SWITCHING ON.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the editorial comments on Dr. Roessler's Paper, the first part of which appears in your last week's issue, it is stated that "transformers under ordinary conditions of working are subjected to potentials of many times their usual value when the primary circuit is *made* or broken." Now, whatever rises of pressure may, under certain conditions, take place at the primary terminals on breaking the circuit (the secondary being open), it is highly improbable that the potential ever rises above its normal maximum at the instant of switching on the transformer. An experiment on this point is described by Dr. Fleming on p. 681, Vol. XXI., of the *Journal* of the Institution of Electrical Engineers, and as the result of this experiment a rise of pressure amounting to 67 per cent. of the normal pressure is recorded. But other experiments by Dr. Fleming failed to show any rise of pressure, and the same negative result has been obtained by other experimenters.

There appears to be some confusion between current rushes and *rises of pressure*. For the latter there seems to be no reliable experimental evidence, and it is highly doubtful whether they ever occur at the instant of switching on. It is absolutely certain, however, that enormous rushes of magnetising current may occur *without the slightest effect on the primary potential difference*. Hence devices whose object is to prevent such rushes of magnetising current are altogether unnecessary, the "rushes" being quite harmless.—Yours, &c.,

University College, Nottingham, November 25, 1895. ALFRED HAY.

STREET LIGHTING BY ARC LAMPS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The interesting criticisms of Mr. Trotter in *The Electrician* of November 22nd deal partly with my own work, partly with Mr. John Hesketh's translation.

It is for me very easy to answer to the first ones. Curves 4, 5, 6, 7, 8 cannot be inexact nor inaccurate, since they are not shown as examples of distribution of any source whatever, but as illustrating geometrical considerations and methods. The sharp peak of Fig. 15 (made perhaps a little too acute on the top by the draughtsman who copied it for photography) explains itself very easily by the choice of the *scales*, which may give to a curve a much sharper peak yet. In fact, *the same curve* drawn on another scale, such, for instance, as Fig. 52 of

Digitized by Google

my second Paper, runs very smoothly. As to the superiority of observed plans over plans calculated from observed photometrical curves, I fail to see it, and may remark, after trying myself, that it is almost impossible to get observed plans accurate, since the arcs rotate continuously around the carbons of the various lamps, and the distribution of light suffers continual change much more difficult to take account of in a street with many lamps in position than in a laboratory with only one lamp. So I think the method of calculating contour lines *from experiments*, first introduced by M. Wybauw, is the best.

As to the criticisms relating to the translation, I can only regret that some errors referred to by Mr. Trotter, and not to be found in the original text, should have escaped Mr. Hesketh's notice as well as my own when hastily glancing at the proofs; but I do not think anybody reading the entire foot-note alluded to, in which the date of Mr. Trotter's valuable Paper is given at full length, could have misunderstood its meaning of justice and friendly courtesy. Moreover, I hope that nobody will contradict my opinion that, on the whole, Mr. John Hesketh has rendered the articles into English in a most clear, competent and elegant manner, and deserves praise far more than criticism.—Yours, &c.,

A. BLONDEL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With reference to Mr. Trotter's letter in your issue of last week, in which he rightly takes exception to the term *foyer* being rendered "lamp," or, still less correctly, "lantern," I may perhaps point out that, as applied to illumination, it is specifically a lighthouse term, and denotes, not so much the "source of light" as Mr. Trotter suggests, but the seat of light, while *feu* denotes "light" or "luminary." The exact equivalent of "source of light" is *source lumineuse* or *source de lumière*. It would hardly do to translate, *e.g.*, *lumière des foyers* by "light of sources of light," or *foyer-heure* by "source of light-hour." I think my friend Prof. Blondel, in the original of his masterly memoir in the *Génie Civil*, uses the very elastic term *foyer* almost throughout in the sense of "arc," or "arc-unit," and in respect of the height of arcs from the ground, in the sense of "focus" or "focal plane."—Yours, &c.,

C. S. DU RICHE PRELLER.

18, Margaret-street, Cavendish-square, W.,
November 25, 1895.

LEGAL INTELLIGENCE.

Fareham Electric Light Company (Limited) v. Fareham Urban District Council.

This action, which is brought for alleged breach of contract, and in which a claim is made for £5,000 as damages, came before the Lord Chief Justice and a special jury in the Queen's Bench Division on Wednesday. The plaintiffs allege a breach of the contract entered into between the Company and the Fareham Local Board (the predecessor of the District Council) in August, 1894, by which the Local Board agreed to purchase the whole of the Company's undertaking and plant at a valuation, and pay a sum of £1,000 in addition to the contract price, on condition that the Company should lay certain overhead wires underground, and should further purchase a new engine. The contract was to be subject to the consent of the Board of Trade and of the Local Government Board, the Company undertaking to use their best endeavours to get the consent of the former and the Local Board the consent of the latter. Valuers were in due course appointed, and the price of the undertaking fixed at £4,866. The defendants, it was alleged, subsequently refused to perform their agreement, whereby the plaintiffs were, it was claimed, considerably damnified. These damages were laid at £5,000.

The defendants, amongst other things, alleged that the resolution to purchase the undertaking was not properly passed, certain members interested in the plaintiff Company having voted, and that the consent of the Board of Trade and the Local Government Board had not been obtained, and that the contract was accordingly void; but in the alternative, in case it should be held that the defendants were liable to damages, they paid £5 into court as sufficient to meet the plaintiffs' claim.

Mr. Robson, Q.C., and Mr. R. M. Bray appeared for the plaintiffs; and Sir Edward Clarke, Q.C., M.P., Mr. Channell, Q.C., and Mr. Glen for the defendants.

Mr. ROBSON, in opening the plaintiffs' case, said that the Company was established in the year 1890 to supply electric light to Fareham in consequence of complaints, which were very general, both by private consumers and the public body, as to the unsatisfactory lighting of the place by gas. The plaintiffs had, he said, carried out their undertaking and obtained the consent of the Board of Trade, but the defendants did not use their best endeavours to obtain the consent of the Local Government Board. On the contrary, a change of members of the Local Board having taken place owing to an election in December, 1894, the new Board passed a resolution not to go on with the matter, and notice was actually given to the Local Government Board that they did not mean to go on with the purchase, and accordingly did not want the loan. It was set up as part of the defence that this consent was not given, but why was it not given? Surely the defendants could not take advantage of their own act.

His LORDSHIP asked whether the defendants were now ready to purchase, or was it a question of damages?

Sir EDWARD CLARKE: If we are liable, that is a question of contract. We have no desire to purchase.

Mr. ROBSON, continuing, said that another defence raised was that the two arbitrators did not sign the award jointly—that was to say, in each other's presence. That the learned counsel characterised as a wretched technicality, and said that if the defendants wished to avoid it they ought to have moved to set it aside within the proper time.

Mr. JAMES BLAKE, the Managing Director of the plaintiff Company, said about 800 shares of £1 each remained unissued, and the Company had issued two sets of debentures. The Company began by supplying electric light to the Fareham Local Board at 3d. per unit, which was 50 per cent. or 60 per cent. below the average price. In arriving at the amount of loss by the Company no allowance was made for depreciation of the plant. Witness was a member of the Fareham Local Board. In accordance with the requirements of the Local Government Board, steps were taken for putting certain of the wires underground, and the plaintiff Company awaited directions from the Local Government Board to proceed. The outgoing Board held office for 18 months. Capt. Ramsey, Admiral Townsend and Mr. Drewitt had all been Directors of the plaintiff Company, and they were all turned out at the election.

The LORD CHIEF JUSTICE asked what was the important point of the defence.

Sir EDWARD CLARKE said the important point was that the Local Government Board, in the discharge of its duty, considering the matters brought before it at the inquiry, could not have sanctioned the making of this loan when they had a definite expression of the opinion of the ratepayers against it.

The LORD CHIEF JUSTICE said he did not read the letter of the Local Government Board in that sense at all, but he should ask the opinion of the jury upon it. He read the letter as asking for an expression of the opinion of the District Council whether they desired the matter to go on or not. He could not doubt that if the District Council had said they wanted to go on, the Local Government Board would have consented. If a representative body entered into a contract its successors must bear the burden of it if lawfully and in good faith imposed upon them. The defendants had done their best to prevent the consent of the Local Government Board being given. Why should the Court look outside that?

Sir EDWARD CLARKE said his contention was that if the Local Board had laid all the facts before the Local Government Board there was no probability of the latter giving its consent to the contract. No doubt there had been a breach of the agreement on behalf of the Board to use its best endeavours, but that was a question of damages.

The LORD CHIEF JUSTICE said he proposed to ask the jury whether they believed that if the existing Council had represented to the Local Government Board that they wished the contract to be carried out, was there any doubt that the Local Government Board would have given its consent; or if they had told the Local Government Board that they thought that the contract was not an advantageous one, but if they broke the contract they would incur heavy damages, whether the Local Board would not in that state of circumstances have given effect to the contract. The carrying out of undertakings entered into in good faith by public bodies was a very important consideration.

Sir EDWARD CLARKE said the Board carried through the contract in known disobedience to the views of the ratepayers whom they were supposed to represent.

Captain Ramsey and Admiral Townsend were called, and gave evidence relative to their holdings in the Electric Light Company, both witnesses asserting that their connection with the Company in no way influenced their vote.

Sir EDWARD CLARKE, in opening the defence, said that undoubtedly there had been a breach of the obligation of the contract with regard to the Fareham Local Board using its best endeavours to induce the Local Government Board to sanction the contract and make the necessary loan to carry it out. It became, therefore, a question of what damages the defendants should pay in respect of this breach, having regard to the consideration of whether, in all the circumstances of the case, it was probable that the Local Government Board would have sanctioned such a loan upon terms which the Local Board would have accepted. It was the way in which Captain Ramsey, Admiral Townsend, and Mr. Drewitt had acted at the end of their term of office, which had induced the ratepayers of Fareham to turn them out of office and elect their opponents. This was a fact which the Local Government Board would have taken into consideration, and remembering that the ratepayers' meeting was adverse to the proposal to purchase, and that the resolution in favour of purchasing was carried by the vote of Captain Ramsey, who had disposed of his shares in the way that had been mentioned, he submitted that the defendants were justified in the course they had taken. It was perfectly clear that if the plaintiff Company had (as seemed probable) been unable to continue its business, the terms on which the District Council would have been able to acquire it would have been much less than under the contract which had been made with so much haste.

The first witness called for the defence was Thomas Robinson Johnson, an officer in the employment of the Local Government Board, who was

Digitized by Google

asked to produce the report of Colonel Marsh, Inspector of the Local Government Board, in reference to the electric light undertaking. Witness objected on the ground that it would be contrary to the public interest, and in this objection he was sustained by his Lordship. He, however, produced all correspondence which had taken place previously.

Various witnesses were then called, and gave evidence as to the feeling of opposition to the proposed purchase which existed amongst the ratepayers of Fareham.

Sir EDWARD CLARKE replied on the defendants' case.

The verdict was for the plaintiff for £3,800. Judgment accordingly. Stay of execution was granted till January 15th, with the view to an appeal.

Edison and Swan United Electric Lighting Company v. Straus.

In the Chancery Division yesterday (Thursday) Mr. Justice Kekewich heard a motion by the defendant to have the action dismissed on the ground that it was frivolous and vexatious.

Mr. SMITH, counsel for the defendant, said the action was one to recover damages for an alleged infringement of the plaintiffs' patent. The claim was afterwards amended, the plaintiffs claiming an injunction to restrain the defendant from selling holders, &c., of electric lamps in connection with their patent. The defendant had undoubtedly been selling these holders and sockets, which were admittedly infringements. Thereupon the defendant's solicitor wrote saying that he would submit to an injunction. That offer was repeated before the Court when last the matter came up for hearing, and the order now before his Lordship was then made—viz., defendant was restrained from selling or otherwise infringing the plaintiff's patent; an inquiry as to damages was ordered, and the rest of the motion was to stand over. The next step was the delivery by the plaintiffs of a most extraordinary statement of claims which simply and solely contained the allegation of the infringement of the patent. Counsel furthermore stated that the costs had been taxed and paid by his client. The situation was hopelessly embarrassing. Counsel presumed that the plaintiffs must file particulars of the breaches. The plaintiffs had made the suggestion that the defendant, a retail dealer, who had bought and sold these things, could not sell them in the open market except on the terms that the plaintiffs had made with the original licencees. This, he supposed, was the cause of the action; but it was not complete.

Mr. J. C. GRAHAM (for the plaintiffs) said that the order of July 30th was to restrain the defendant from infringing two specific articles; but before that the plaintiffs found out that this gentleman was selling sockets in a way in which he was not allowed to sell them. They complained of that as an infringement, as to which they got an order, but there were other things which were in the claim; therefore this was a proper case to go to trial. The plaintiffs complained of a general infringement.

His LORDSHIP asked if it were the case that the defendant was selling the articles at a larger discount than was authorised.

Mr. GRAHAM said that was so. It was very similar to the incandescent case. It was a question of contract, and the plaintiffs complained of the threat by the defendant to continue to sell sockets and holders made according to letters patent. He submitted that there was no ground to support the motion to strike the case out as having no cause of action.

His LORDSHIP said he would not stop an action like this. He would, however, make no order in this motion, costs to be costs in the action.

Whiffen and others v. The Crompton Electric Supply Company of Australia (Limited).

This case came before Mr. Justice Kekewich in the Chancery Division on Tuesday last on a motion for judgment. Mr. Butcher said that he had to ask for judgment by consent in a Preferred Debenture-holders' action for some £10,000 out of total issues of about £20,000, interest on which was in arrear. The learned counsel stated that all parties to the suit were now legally represented, and that a receiver and manager had already been appointed under a declaration of charge, but his time having expired, it had temporarily been renewed by Mr. Justice Stirling. Negotiations were proceeding for the sale of the business, and he now asked that the receiver and managership should be continued. His Lordship assented to this, the arrangement to expire on the last day in April, unless further extended. It was agreed to adjourn further consideration on other matters in connection with the Company to Chambers.

Cohen v. The Electricity Supply Company for Spain (Limited).

This was an action heard in the City of London Court yesterday (Thursday), and was a claim made by Mr. Arthur Cohen, electrical engineer, of Old Broad-street, E.C., who sought to recover the sum of £96 from the defendant Company for 16 electrical transformers supplied to them at £6 each. For the plaintiff, it was said that Mr. Lowry, when in the service of Mr. Robert Hammond, consulting engineer to the defendant Company, went to the plaintiff and asked him if he could sell the defendants 16 transformers. The plaintiff placed the transformers in Lowry's hands for sale on commission, and Lowry succeeded in selling the goods to the defendants through Mr. Hammond. The latter insisted upon the transformers going through a test, which he prescribed at the Electrical Standardising Institute, Faraday House, W.C. Only 12 of the transformers would stand the test, and those were accepted by the defendants, who subsequently shipped them to Spain. The plaintiff afterwards sent in the invoice, and was then told that the defendants had paid Lowry £62 out of the £72 due for the 12. The defence was that the defendants bought the transformers from Lowry direct without any knowledge at all that they belonged to the plaintiff.

Mr. HAMMOND said he knew Lowry for some years, he having been in his (witness's) service, and after they parted company he made Lowry an allowance of £4 per week until he obtained work elsewhere. The defendants paid £62 to Lowry, and they deducted £10 to pay the Faraday House Institution for certain repairs which were executed to the transformers before the tests were made. They now paid £6. 14s. into Court, and admitted that a further 30s. was due.

The Jury, after further evidence, found for the plaintiff, and judgment was entered accordingly.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

SPECIAL NOTICE.—The 1896 (fourteenth annual) edition of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK is in active preparation, and orders for Advertisements and Subscriptions (5s. 9d. post free, abroad 6s. 6d.) should now be sent in. The usual circulars, &c., are now being sent out. Full particulars post free on application.

NEW BOOKS AND EDITIONS.

The following New Books and Editions of "THE ELECTRICIAN" SERIES *can be obtained of the Booksellers or direct from the Publishing Offices:—*

LABORATORY NOTES AND FORMS.—With the above title, we have ready a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators, and Students. The object of this series is the saving of the time of the teacher and his assistants, and to serve as a record of the work done by the student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen nett; in sets of any three 1s. nett; or the set of Twenty Elementary (or Advanced) Exercises can be obtained price 5s. 6d. nett. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. nett, or in handy portfolio, price 12s. nett, or bound in strong cloth case price 12s. 6d. nett *(now ready)*. Strong portfolios can be had, price 1s. each. A full prospectus sent post free.

"THE WORK OF HERTZ."—By Dr. O. J. Lodge, with many original illustrations, price 2s. 6d. nett, is now ready.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is now ready. The book is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free. Prospectus post free.

"ELECTRIC MOTIVE POWER."—A new work, by Mr. Albion T. Snell with this title, is now ready, containing the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. The book is well printed, on good paper, and contains 230 illustrations. Price 10s. 6d. post free (abroad 11s.).

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book by Messrs. W. Geipel and H. M. Kilgour, is now ready; price 7s. 6d., by post 7s. 9d. (abroad 8s.). A large paper edition with wide margins can be supplied, price 12s. 6d., post free 13s. (abroad 13s. 6d.). Prospectus on application to the Publisher.

"DRUM ARMATURES AND COMMUTATORS."—By Mr. F. Marten Weymouth, is also ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

'THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready; price 7s. 6d. (abroad 8s.). Prospectus on application.

"PRACTICAL NOTES FOR ELECTRICAL STUDENTS."—By Messrs. A. E. Kennelly and H. D. Wilkinson, price 6s. 6d., post free.

"THE ART OF ELECTROLYTIC SEPARATION OF METALS."—A second issue of Dr. Gore's book is now ready, price 10s. 6d. post free.

A LARGE-SHEET TABLE, giving full particulars of the Electricity Supply Stations throughout the Kingdom, can now be supplied mounted on stout board, with cord for hanging. Price: Varnished, 3s. 6d.; Unvarnished, 3s.—each post free. A Map showing positions of Supply Stations throughout the country is mounted on the back of the Table, and a Coloured Map of Metropolitan Electric Lighting Areas and a large sheet of Electricity Supply Statistics are also mounted on some copies, the price of which complete, post free, is 5s.

A SHEET TABLE showing Total Capital Outlay and Receipts and Expenditure for the year 1894 of the Statutory Electric Supply Undertakings of the Metropolis is now ready, printed on thick paper. price 6d.

A SHEET TABLE giving similar particulars in relation to Provincia Statutory Electric Supply Undertakings is now ready, printed on thick paper, price 6d.

TENDERS INVITED.—The Great Northern Railway Company invite tenders for the supply of new and the purchase of old stores, including telegraph and electric lighting stores and material. Tenders by December 7th to the Secretary, King's Cross Station, London, N.

——— The Minister of Industry of the State of Pernambuco (Brazil) invites plans and schemes for the electric lighting of the town of Recife. Plans, &c., must be in by January 20th.

Digitized by Google

TENDERS INVITED.—The Municipal Authorities of Betanzos (Galicia) are inviting tenders for the concession for the electric lighting of the town for 25 years. Tenders to El Ayuntamiento de Betanzos, Spain, by December 28th.

——— The Municipal Council of Alexandria (Egypt) invite offers for the concession of the tramways on the basis of an annual rental.

——— The Committee of the Ryhope and Silksworth Industrial and Provident Society invite tenders for supplying and fixing accumulators in connection with their Ryhope electric light installation. Tenders by 2 p.m. to-morrow, Saturday.

——— Tenders are invited for supplying and fixing electric lighting plant at Messrs. P. and F. M'Glade's stores, Belfast. Tenders to Messrs. George Combe and Co., consulting engineers, Castle Lane-place, Belfast.

TENDERS ACCEPTED.—At the meeting of the Metropolitan Asylums Board the Brook Hospital Committee reported that they had invited tenders from the firms agreed upon for the supply of the necessary plant for the electric light installation at the Brook Hospital, and that the following tenders had been received :—

	Engines, dynamos, &c.	Batteries, &c.	Switchboards, &c.
*Siemens Bros. and Co.	£2,004	£475	£527
*J. H. Holmes and Co.	2,100	475	350
Mather and Platt	2,605	465	415
Brush Company	2,428	378	480
T. Parker (Limited)	2,312	521	412
Johnson and Phillips	2,170	360	630
Electric Construction Company..	2,142	509	370
Crompton and Co., Chelmsford...	2,139	551	366
W. H. Allen, Son and Co.	2,060	—	—

* Accepted as shown in block figures.

The Committee recommended that subject to the sanction of the Local Government Board, the tenders of Messrs. Siemens Bros. and Co., for the supply of the engines, dynamos, &c., at £2,004, and batteries at £475, be accepted, and that the tender of Messrs. J. H. Holmes and Co. for the supply of the switchboards, &c., at £350 be accepted, and these recommendations were approved. The Committee further reported that they had received the following tenders for the wiring work and supply of fittings in connection with the installation of the electric light at the Brook Hospital and Ambulance station :—

	Ambulance Station.	Brook Hospital.
Julius Sax and Co. (*accepted*)	£213 9 11	£4,666 8 4
Slaters (Limited)	534 0 0	6,217 0 0
Hollingam and Saword	400 2 6	6,179 0 0
H. F. Joel and Co.	336 0 0	5,954 0 0
C. Nathan	630 0 0	5,063 0 0
Pritchetts and Gold	279 0 0	5,279 10 0
Strode and Co.	334 0 0	4,878 0 0
Edmundson's (Limited)	350 15 0	4,643 19 0
Fowler, Lancaster and Co.	228 0 0	4,685 12 6
Brush Company	192 0 0	4,547 0 0
Electrical and Gen. Engineering Co.	289 0 0	3,169 10 0

On the Committee's recommendation the tenders of Messrs. Julius Sax and Co. for the total sum of £4,879, 18s. 3d. were accepted.

——— The following tenders were received by the Bedford Urban Sanitary Authority for the supply of surface condenser and air pump and a centrifugal pump with engine for their electricity works :—

Robert Stephenson and Co. (Limited), Newcastle-upon-Tyne (*accepted*)	£467 0 0
Gwynne and Co., London	440 0 0
Wright's Patent Heater Condenser Company, 16, Great George-street, Westminster	541 0 0
Tangyes (Limited), Birmingham	546 0 0
W. H. Allen, Son and Co., Bedford	560 0 0
Humpidge, Holborow and Co. (Limited), Stroud	650 0 0
Thos. Metcalfe, Phœnix Foundry, Bradford	747 12 0
Stevenson and Co. (Limited), Canal Foundry, Preston	790 0 0

——— The Board of Control (Dublin) have accepted the tender of the Northern Counties Electric Construction Company for wiring and fitting up the Killarney District Lunatic Asylum for the electric light for the sum of £1,555.

——— The tender of Messrs. Westwood and Sons, Dundee, for fitting electric bells at the West Poorhouse, Dundee, has been accepted by the Guardians.

SALES BY AUCTION.—Our advertisement columns contain particulars of the sale by auction, by Messrs. Wheatley Kirk, Price and Goulty, on Thursday next, of the entire contents of the works premises at Broadway, Walham Green, S.W., in the occupation of Messrs. Russell and Co., who are giving up business. Catalogues are now ready and can be obtained from the auctioneers, and from Messrs. Russell and Co., 11, Queen Victoria-street, E.C.

——— The Reading Electric Supply Company having completed their new electricity station, Messrs. Wheatley Kirk, Price and Goulty give preliminary notice of the piecemeal sale by public auction, at an early date, of the entire contents of the Company's old station, the Island, Reading, comprising engines, boilers, combined lighting sets, dynamos, &c. Further information is given in our advertisement columns.

SALE BY TENDER.—Messrs. Percy Huddleston and Company announce a sale by tender of the surplus plant at the Woking (Surrey) Electric Light Station. Some particulars are given in our advertisement columns.

APPOINTMENT.—The Ealing District Council received 45 applications for the position of chief electrical engineer, and they have appointed Mr. Knight at an annual salary of £240, increasing to £300 by yearly increments of £30. Mr. Knight is at present in the employ of Messrs. Siemens Bros. and Co.

APPOINTMENT VACANT.—The Lighting Committee of the Wolverhampton Corporation require a clerk and canvasser in the office of the borough electrical engineer. Salary £100 per annum. Applications to Mr. F. Harman Lewis, Borough Electrical Engineer, Town Hall, Wolverhampton, by Saturday, December 7th next. Further particulars appear in our advertisement columns.

VACANCY.—The Woolwich District Electric Light Company have a vacancy for a pupil at their generating station. Some further particulars are given in an advertisement elsewhere.

DISSOLUTIONS OF PARTNERSHIP.—Messrs. Henry and Arthur Davis, carrying on business as electrical engineers and scientific instrument makers at All Saints' Works, Derby, and 118, Newgate-street, London, under the style of John Davis and Son, have dissolved partnership. Mr. Henry Davis will continue the business under the present title.

——— Messrs. J. S. Bolton and T. Harrison, carrying on business as electrical engineers at Collingwood-street, Newcastle-on-Tyne, under the style of Bolton, Harrison and Co., have dissolved partnership.

BANKRUPTCY.—Notice is given of the release of the trustee (the Official Receiver of the Halifax County Court) in the bankruptcy of John Henry Brown, electrical instrument case maker, South-street and Archer-street, Halifax.

PETITION FOR WINDING-UP.—A petition for the compulsory winding-up of the Herculite and Electrical Manufacturing Company (Limited) has been presented by the Harburg and Vienna India Rubber Company, and will be heard at the Royal Courts of Justice, Strand, London, on Wednesday next. Mr. W. H. Dale, 46, Finsbury-circus, London, E.C., is solicitor for the petitioner.

ADVANCE IN PRICES.—It will be remembered that in our issue of November 15th notice was given that the leading firms of electric wires and cable makers had decided, owing to the increase in the price of raw material, to advance the prices of their manufactures. We now have official intimation from the Brush Company that on and after January 1st next an advance of 10 per cent. will be made in their list prices for all Brush specialities excepting arc and incandescent lamps. Taking into account the complaints that have been made by the leading engineering firms as to the very narrow margin of profits on recent contracts, this seems a step in the right direction.

RECORDING INSTRUMENTS.—The recording instruments supplied to the Bristol and also to the Coventry Electric Tramways (an account of which was given in our last issue) were of the well-known make of Mr. J. Pitkin, of Red Lion-street, Clerkenwell, London. This firm has supplied instruments to the Aberdeen, Blackpool, Sheffield, Scarborough, Edinburgh, Shrewsbury, Finchley-road, and other lighting stations, and, we are informed, have orders in hand for Norwich, Sheffield, &c.——We have received from Mr. Pitkin, of Red Lion-street, a copy of his new price list of ammeters, voltmeters, &c., &c., in which Major Holden's well-known hot-wire recording instruments figure prominently. Owing to the fact that the indications of these instruments are not liable to be vitiated either by external magnetic disturbances or by the friction of the pen on the recording drum, they are specially suitable for central station switchboards, and we are not, therefore, surprised at their vogue in this connection.

"ADRESSBUCH DER DEUTSCHEN MASCHINEN-INDUSTRIE."—We have received a copy of this work, which is published in Dresden by Herrn. Friese and von Puttkamer, who are represented in this country by Messrs. Sampson Low, Marston and Co. The Address-book is published annually, this being the second publication. It is edited by Herr Holzt, and in addition to a very complete index of German electrical firms, contains as a frontispiece an excellent portrait of Dr. Werner von Siemens and a somewhat lengthy obituary notice. The original of the portrait is the same as that used for the recent steel-plate supplement to *The Electrician*. The book contains nearly 1,300 pages, is well printed, and the binding is a very fine example of German block making.

READY RECKONER.—There is of a certainty no limit to the number of publications of what may be termed the labour-saving

Digitized by Google

kind, but certainly one of the most useful recently issued, is a handy ready reckoner for wages and costing purposes, compiled and published by Mr. K. Openshaw, of Wyke Regis, Weymouth. The tables are principally useful for wage-paying purposes, and are based on a 54-hour week—that is to say, if a workman is paid at the rate of 33s. per week, and works 60 hours, on that basis the table without trouble or calculation gives the figures. There are 300 sets of figures in all, which may be taken to cover the whole of the probable requirements of such a work.

ABERDEEN.—The work of installing the electric light at the Public Library has just been completed. About 180 16 c.p. incandescents are employed, and the installation has been carried out by Messrs. Shirras, Laing and Co.

BERMONDSEY (LONDON).—At the last meeting of the Vestry the Law and Parliamentary Committee's report, recommending that the application of the Capital and Counties Electricity Supply Company for a Provisional Order be opposed, was adopted.

BEXHILL (SUSSEX).—At the last meeting of the District Council the Highways Committee's report, recommending the Council to consent to the application recently received by them for a Provisional Electric Lighting Order for the district, was approved.

BRIGHTON.—At a meeting of the Lighting Committee, residents in Sillwood-street complained of the insufficient lighting of that thoroughfare. The Committee have decided not to do the extension work piecemeal. They are hopeful of being able early next year to light the remainder of the streets where the mains were laid by incandescent lamps to be affixed to the present gas standards, and with this object the borough electrical engineer (Mr. A. Wright) has been requested to prepare a scheme.

CAMBERWELL (LONDON).—At their last meeting the Vestry discussed the report of the General Purposes Committee, which recommended that sanction be given to the application of the County of London and Brush Provincial Company for a Provisional Order. After a long debate, an amendment by Mr. Phillips, "That the assignment of a monopoly for electric lighting in this parish to a private company for 42 years demands such grave consideration that the Vestry hereby appoints a Special Committee to consider and report upon the question of the lighting of the parish," was carried by 48 votes to 35.

CARDIFF.—At the last meeting of the Lighting and Electrical Committee the Chairman (Mr. Ald. Carey) stated that a Sub-committee had been appointed to confer with the Exhibition Committee on the subject of lighting the Exhibition by electricity. They would require extra plant capable of giving an additional 350 H.P. or 400 H.P. before they could undertake to supply the Exhibition authorities with current. It was proposed to employ 101 arcs and 539 incandescents. The matter would have to be taken up at once, as it involved an application to the Board of Trade. If they set to work at once everything ought to be in readiness to supply current to the Exhibition in May. The extra plant was really necessary for town purposes at the present moment, and it could be permanently utilised on the one expenditure for erecting. The matter was referred to the Sub-committee to report upon. A suggestion was made that the Town Hall and the square in the rear be lighted electrically, but the borough engineer (Mr. Harpur) stated that it would be impossible to do this until fresh plant was laid down.——The Corporation have received the formal sanction of the Local Government Board for borrowing £12,885 for electric lighting purposes, the loan to be repaid in 25 years.

CHELTENHAM.—The Corporation's electricity works are now running continuously day and night, and current is at all times available. Up till last week the machinery had been shut down during the day hours on Sunday, but owing to the increased popularity of the light by private consumers it has been decided that no break shall take place in the supply. The supply of current for power purposes is also making satisfactory progress. The Corporation have decided to proceed with their Bill before Parliament to acquire the gasworks for the town. This step is taken practically in opposition to an application to Parliament by the gas company.

CHURCH LIGHTING.—Canon Duckworth's church (St. Mark's, Hamilton-terrace, W.) is to be lighted electrically. The Canon was recently presented with a silver service and a cheque for 300 guineas, and in acknowledging the gift he stated that it would enable him to defray the cost of installing the electric light in his church.

DARWEN.—It has been decided to light the Technical School electrically, and several of the leading tradesmen and ratepayers are urging the Town Council to put down electric generating plant at the Schools (which are the property of the town) capable of supplying current for lighting the centre of the town.

EALING.—At the last meeting of the District Council the Surveyor reported that they had received applications for an equivalent of 6,234 8 c.p. lamps, and that 4,273 had already been connected.

ELECTRICITY AND SANITATION.—The Medical Officer of Health to the Corporation of the City of London (Dr. Sedgwick Saunders), in his annual report, recently issued, points out that the great extension of electric lighting installations within the City area has marked what he describes as a new era of sanitation, and he anticipates that much benefit must accrue to the moral and physical condition of the employés in the large commercial establishments which have adopted the electric light who had been condemned to work in badly lighted and overheated basements. A tendency also of the improved lighting is that attention is called to other sanitary weaknesses, leading to their abolition and the introduction of improvements all round.

ELECTRIC LOCOMOTIVES.—A Paper on this subject was read last week before the Manchester Association of Engineers. The author, Mr. T. Daniels, pointed out that there are now 81 electric railways constructed by European engineers, with a total length of about 440 miles. Of these the largest were in England—viz., the City and South London Railway and the Liverpool Overhead Railway. The author's claims for the electric railway and tramway were increased comfort to passengers, greater speed, cleanliness, ease of lighting, heating and ventilating, and the improved braking of the electric car. Finally, the author recommended the railway companies to set about developing electric feeding lines in thickly-populated districts in order to meet the opposition of competing electric railways which were likely to spring up and deprive the older companies of much of their local traffic.

ELECTRIC TRACTION NOTICES.—Some variety is observable in the traction notices appearing in the *London Gazette*. In some cases power is asked for the substitution of electric motive power throughout the systems, in other cases electric or other motive power. The Portsmouth Street Tramways Company are in the former category, while the Corporations of Sheffield, Swansea, Blackpool and Newcastle, and the Belfast Street Tramways Company, are amongst those bodies which seek for powers to introduce electric or other motive power. Notice is also given of intention to apply for powers for the incorporation of companies—(1) to construct an electric tramway between Kidderminster and Stourport; (2) to construct tramways in Halifax and neighbourhood (electric or other motive power to be employed); (3) to construct tramways in the boroughs of Ashton-under-Lyne and Hyde, the urban districts of Denton and Audenshaw, the rural district of Limehurst, and the districts of the Parish Councils of Waterloo and Bardsley (electric or other motive power to be employed); (4) to construct tramways in Sheffield and Rotherham (use of electric or other motive power); (5) to construct a light railway between Derby and Ashbourne (use of electric power); (6) to construct tramways in Blackpool and Fleetwood (use of electric or other motive power). In the applications for powers to construct tramways between Farnborough and Aldershot a clause for sanction to use electric or other motive power is also included. In Ireland official notice has been given by the Dublin and Southern Tramways Company and by the Dublin United Tramways Company of application being made for powers to construct electric tramways in Dublin. In addition to the above the *Gazette* notices include several applications for powers to construct light railways, the proposed motive power for which is not stated.

EXTENSIONS OF TIME.—Notice is given that the Baker-street and Waterloo Railway Company intend to apply to Parliament for an extension of time for the construction of the line authorised by the Baker-street and Waterloo Railway Act (1893). The City and South London Railway Company intend to apply for an extension of time for the completion of the works authorised by the City and South London Railway Act (1893). The Brighton and Rottingdean Seashore Electric Tramroad Company intend to apply for an extension of time for the construction of the works authorised by the Brighton and Rottingdean Seashore Electric Tramroad Act (1893). Application is also to be made for an extension of time for the construction of the Blackpool, St. Anne's and Lythen Tramways and for the use of electric or other motive power.

FOLKESTONE.—At a special meeting of the District Council last week it was decided to apply for a Provisional Electric Lighting Order, and it was also decided to oppose the Capital and Counties Electricity Supply Company's application for a similar Order.

GAS COMPANIES AND THE ELECTRIC LIGHT.—The Ilfracombe Gas Company gives official notice of its intention to apply for powers in the next session of Parliament to supply electric current for lighting, heating and motive power purposes.

GAS TO THE RESCUE.—At the meeting of the Edinburgh and Leith Gas Commission on Monday last, Bailie Kinloch Anderson, in commenting on the engineer's report for October, said that they were "combating very bravely the invasion of the electric light,

Digitized by Google

Since May 15th there was an increased consumption of over 18,000,000 cubic ft. of gas, but that the influence of the electric light was now being seriously felt. In Edinburgh there was an increase of under 700,000 cubic ft., whereas in Leith they had an increase of over 4,000,000 cubic ft., which had been the proportionate increase for some time, only there the electric light was not in operation. So Leith was coming to the rescue again, and saving the Gas Commission from destruction. He had no doubt they would be able to hold their own in the future"—so long as the electric light held off.

HAMMERSMITH (LONDON).—The Electric Lighting Committee recently presented a report on the tenders and schemes sent in for lighting the compulsory area of the district electrically. The Committee recommend that they be empowered to obtain such expert advice as may be necessary, at a cost not exceeding 200 guineas, to enable them to make a complete report on the matter.

HAM (SURREY).—At the last meeting of the District Council it was decided to ask the Richmond Town Council to extend their electric fire-alarm system towards Ham.

KINGSWOOD (BRISTOL).—At the last meeting of the District Council it was reported that the Great Western Electric Light Company proposed to apply for a Provisional Electric Lighting Order for Kingswood and St. George.

LAMBETH (LONDON).—At a special meeting of the Vestry last week it was decided to appoint a special committee of eleven members "to consider carefully all the information obtainable on the electric lighting question, and to report thereon to the Vestry."

LIVERPOOL.—Mr. Charles Rettie, of Geraint-street, has recently completed the fitting and lighting of Dunthorne's Rembrandt Gallery, in Castle-street, for the electric light. The gallery extends from Castle-street to Back Castle-street, and is a portion of a new stone building, the front of which is of highly artistic design. The gallery is divided into three sections, front, centre and back, and these have 60 lights fitted, independent of the lights in the workshop in basement. Parquet flooring is used throughout the galleries, the pervading colour in which is green bronze, and, as will be readily understood, the electric light has proved most effective. There are eight complete circuits, which come down on a switchboard especially designed and containing one D.P. 50-ampere switch and four S.P. 25-ampere switches. The ornamental shell fittings in the windows facing front to the street have proved very attractive.

LIVERPOOL.—At the last meeting of the Lighting Committee of the City Council it was stated that the Liverpool Electric Supply Company had sealed the contract extending the time for the purchase of the Company's undertaking to six weeks after the Act for its acquisition shall have been passed.

LLANDUDNO.—At the last meeting of the District Council the Electric Lighting Committee's report recommending the appointment of Messrs Kincaid, Waller and Manville as consulting electrical engineers, was discussed, but it was eventually decided to invite schemes for a system of electric lighting, and to submit these to an electrical expert.

LONDON COUNTY COUNCIL.—At the weekly meeting on Tuesday it was agreed, on the recommendation of the Fire Brigade Committee, that agreements be entered into with the Post Office in respect of electric fire alarms in Islington and Poplar, and in respect of telephonic communication between several of the City and suburban fire stations. The Post Office asked permission to carry a wire across Nunhead Green, but the Council declined to allow this, as the Green is a recreation ground. Permission was given to place the wire underground.

MEVAGISSEY.—At the special meeting of the Parish Council it was announced that a company would be formed for lighting the district. A sufficient number of shares have been applied for to warrant them in proceeding with the matter.

NEWPORT.—It has been decided to make further electric lighting extensions at a cost of about £1,000. It was stated at the last meeting of the Council that the electric light scheme had proved to be a great success.

PETERBOROUGH.—The borough engineer (Mr. Gill) recently presented his amended report on the electric lighting question, and the matter was debated at great length at a meeting of the Town Council last week, but was again referred back for the purpose of further ascertaining the amount of support likely to be accorded to the scheme.

PROVISIONAL ELECTRIC LIGHTING ORDERS.—The Corporations of Bangor, Devonport, Gloucester, Liverpool, and Margate, the Bath Urban Authority, the Vestries of St. Mary, Newington, and St. Mary, Battersea (London), the Urban Councils of Colwyn Bay, Folkestone, Kettering, and Sale, and the Queenstown Commissioners give notice of their intention to apply to the Board of Trade for Provisional Orders under the Electric Lighting Acts 1882 and 1888. In their Improvement Bill the Corporation of Darlington also apply for powers to extend the provisions of the Darlington Electric Lighting Order (1890). The following companies also give notice of their intention to apply for Provisional Electric Lighting Orders: Bedford Electric Light Company (for Berkhamsted and Northchurch), Liverpool District Lighting Company (for Great Crosby and Waterloo, and for Allerton, Little Woolton, Much Woolton, Childwall and Garston, Lancs.), Newmarket Electric Light Company (for Newmarket), County of London and Brush Provincial Company (for the district of St. Saviour's District Board of Works, the parishes of St. Mary (Newington), St. Mary (Lambeth), St. Giles (Camberwell), St. Mary (Battersea), all in London; and also for Ipswich and Lincoln), British Insulated Wire Company (for Prescot), Windermere and District Electricity Supply Company (for Ambleside); J. C. Howell, Limited (for Merthyr Tydfil).

RHONDDA.—At the last meeting of the District Council the Electric Lighting Committee's report on the electric lighting of the Valley was presented. The Committee have had three schemes under consideration: (1) The erection of two independent generating stations in the Rhondda Fach and in the Rhondda Fawr Valley; (2) to avail themselves of the electrical installations at the collieries in the district, as offered by the colliery companies upon certain terms; and (3) a scheme by which they could utilise water-power for driving turbines. The Committee, as there is an abundance of available water in the valleys, recommend the adoption of the latter scheme. The consideration of the question was adjourned for a fortnight.

ROCHDALE.—At the last meeting of the Watch Committee of the Town Council it was resolved to erect a public police and fire-alarm system in the town. The Committee have decided to adopt Messrs. W. A. Shaw and Co.'s system of electric alarms.

ST. PANCRAS VESTRY (LONDON, N.W.)—The annual report of Mr. A. E. Pycraft, the chief clerk to the Vestry's Electricity Department, has just been issued, and shows that considerable progress has been made in the supply of current during the period under review, the increase being set out as under:—

Number of consumers	44	per cent.
Sale of current at 6d. per unit	17½	„
Sale of current at 3d. per unit	212	„
Supply to private houses (exclusive of trade premises, &c.)	49	„
Number of lamps connected (equiv. 16 c.p.)	22	„
Highest load point	23	„
Total sale of current (excluding public lighting)	33	„
Money value of current consumed	26	„

In May last the total number of consumers was 373, the total current supply representing 16,751 16 c.p. incandescents, 129 arcs and 27 motors. But the large increase in consumption is specially noticeable in the private supply, evidencing a considerable increase in popularity for the light. After all charges for repairs and maintenance, including rates and taxes, have been paid, the balance available to meet interest and payments of the instalments on loans, and including the interest on the bank overdraft (amounting in all to £5,379. 19s. 2d.) is £7,233. 1s. 4d., or, after making proper provision for all debts, &c., a net profit on the year's work of £1,753. 18s. 2d., which is equivalent to 6 per cent. on the total capital expenditure, and would, if the undertaking were the property of a company be available for distribution amongst the shareholders. A considerable reduction has been made in the charge for public lighting, although additional lamps have been erected. This is owing to the reduction in the charge per unit from 6d. to 5d. for public lighting and to other economies. The report is throughout of an extremely satisfactory character, and the outlook for the Vestry's electric lighting scheme is described as most promising.

THE FIRE AT CROMPTON'S.—It is gratifying to announce that in spite of the damage caused by the recent fire at their Chelmsford works, Messrs. Crompton and Co. are still able to ensure prompt deliveries of some of their special manufactures, especially arc lamps and arc lamp accessories. This department not having been damaged is in full working order. The Company's installation department is also unaffected by the fire, as is also the heating and cooking department at 35, Queen Victoria-street, E.C. Immediate steps have been taken to resume the manufacture of dynamos, a considerable portion of the stock having been saved. In a circular to hand Messrs. Crompton and Co. ask for copies of any orders remaining unexecuted, statements of account and invoices, sketches, &c., to be supplied to them owing to the fire having completely destroyed all trace of these documents.

THE SOUTH STAFFORDSHIRE TRAMWAYS.—Some excitement has been caused in the Handsworth, West Bromwich and Tipton districts, through which the South Staffordshire Tramways Company's line passes, owing to the fact that the licence granted by the Board of Trade for the use of steam on these sections of the system will expire at the end of the current year. It would appear that the local authorities in the districts are not disposed to assist

Digitized by Google

in obtaining further concessions for the Company, and that the Board of Trade has intimated that the traffic will cease unless the Company is prepared to introduce a new system at once. At a meeting of the Tipton Urban District Council on Tuesday it was announced that a syndicate had come forward which was prepared to discharge the liabilities of the present South Staffordshire Tramways Company, and to equip a portion of the line with cable and the remainder (that between Handsworth and Carter's Green) with the overhead electric system. The districts through which these sections of the Company's lines pass are densely populated, and a cessation of traffic would cause great public inconvenience.

TOTTENHAM (MIDDLESEX).—The General Purposes Committee of the District Council have presented a report on the electric lighting question, which states that unless there is a large demand for electric current for private lighting the cost of street lighting would be greater than that of gas. The Committee recommended that, in case the Council decided to proceed further with the matter, an electrical expert be appointed to prepare a report and devise an electric lighting scheme for the district. After considerable discussion, this report was adopted, and notice of motion was given for the next meeting that schemes, reports and estimates be invited from electrical engineers, and that premiums of £50, £30 and £15 be offered for the three best schemes.

WAKEFIELD.—A Local Government Board inquiry is to be held to-day (Friday) into the application of the Town Council for sanction to borrow £25,000 for electric lighting purposes.

WELLS.—At their last meeting the City Council formally resolved to apply for an electric lighting Provisional Order, and voted £50 as a deposit with the Board of Trade. The Sanitary Committee reported that as a result of their negotiations with the gas company they had offered their works to the Council for £19,680, and the Committee had offered £12,700, which the Company had declined. A proposition to offer £15,000 was rejected, and the negotiations between the parties are consequently, at an end—at least for the present.

WILMSLOW (MANCHESTER).—At the last meeting of the District Council a letter was read from Mr. S. V. Clirehugh, stating that he was acting on behalf of a company which was anxious to obtain powers to supply electric current in the Wilmslow district, and asking for the Council's consent to its application for a Provisional Order. After discussion a committee was appointed to confer with Mr. Clirehugh on the subject.

PATENT RECORD.

A record of Applications for Patents and Patent Specifications Published is compiled for this journal by MR. J. C. CHAPMAN, *Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any information on the subject may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The Specifications of Applications for Patents are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions, or where complete specification accompanies application an asterisk is suffixed.*

November 4, 1895.

20,164A. S. O. COWPER-COLES, M. ULCOQ, W. M. GUTHRIE, and C. R. G. SMYTHE. London. Improvements in or connected with cathodes for use in the electrolytic deposit of metals.

20,790. F. E. W. BOWEN. London. Improvements relating to filaments for electric incandescent lamps.

20,801. O. VON MORSTEIN. London. An improved means for electrically lighting gas jets from a distance.*

20,807. R. MAYER. London. Process for the production of electrotypes or galvanos with engraved or sunk drawings or designs.*

20,815. E. T. MIDDLEMASS. London. Improvements in coin-released machines which are electrically driven.

20,821. V. FABRIS. London. An improved reflector for electric arc lamps.

20,824. W. GRIMES. London. Improvements in or relating to electric batteries.

20,828. W. ROWBOTHAM. London. Improvements in or relating to primary electric batteries.

20,835. A. J. P. WITAKER and F. G. TREHARNE. London. Improvements in or relating to insulating conduits or tubing and connecting boxes for containing electrical conductors.

November 5, 1895.

20,843. C. P. SHREWSBURY, F. L. MARSHALL and J. L. DOBELL. London. Improvements in electric batteries.

20,883. P. M. JUSTICE. London. Improvements in electric systems. (W. H. Nixon, U.S.A.)*

20,904. J. DEVONSHIRE. London. Improvements in controlling electric motors by the three-wire system. (W. B. Potter, United States.)*

Arthur W. Cohen, gentleman	10
J. Herbert Farmer, solicitor	25

The first Directors are: Max Margowski, Joseph W. Cohen and T. S. Hopcraft.

BRITISH MOTOR SYNDICATE (LIMITED).—This Company was registered on November 21st, with a nominal capital of £150,000, in £1 shares, to carry into effect an agreement referred to in the Articles of Association, to use, develop, grant licences in respect of or otherwise turn to account any patents, brevets d'invention, licences, concessions, &c.; to manufacture, sell, or otherwise deal in motors of every description, cycles, vehicles, and carriages of all kinds, and to carry on the business of electricians, mechanical engineers, machinists, wire drawers, metallurgists, &c. The first subscribers, with one share each, are: H. J. Lawson, engineer; J. D. Newton, G. G. Hay, E. R. Baines, W. H. Robson, J. P. Aldridge and E. W. Pidgeon.

DAVY ELECTRICAL CONSTRUCTION COMPANY (LIMITED).—This Company was registered on November 19th, with a capital of £10,000, in £1 shares, to carry into effect an agreement made between William J. Davy and the Company to work and develop all or any of the properties by the said agreement agreed to be sold, and any other property hereafter acquired by the Company, &c. The first subscribers, with one share each, are: Arthur Simmons, W. A. Pittman, Edward A. Leadam, E. M. Slaughter, Reginald Young, Herbert J. Wells and A. J. Wells. The first Directors are: William T. Douglas, Ernest Berthier and William J. Davy.

LONDON AND PROVINCIAL TRACTION COMPANY (LIMITED).—This Company was registered on November 25th, with a nominal capital of £100,100, divided into 10,000 £7 per cent. cumulative £10 Preference shares and 100 £1 Ordinary shares, to enter into and carry out contracts, concessions, or other grants in Great Britain or elsewhere, for constructing, purchasing, or working railways, tramways, telegraph and telephone lines, electric lighting, electric, hydraulic, and other works, and for the equipment of any such undertakings or works with electric or other plant, stock and apparatus, and to carry on the business of contractors. The subscribers, with one share each, are: D. Parrish, A. Parrish, engineer, T. Werner, F. R. Harris, S. Neumann, L. Hirch, and H. R. Butin.

EASTON, ANDERSON AND GOOLDEN (LIMITED).—The annual return to November 13th has been filed. The nominal capital is £200,000, in 10,000 Preference and a like number of Ordinary shares of £10 each; 5,986 of the former and all the latter have been taken up, and 2,886 Preference and 9,320 Ordinary have been issued as fully paid. The full amount has been called on the remaining 680 Ordinary and 3,100 Preference shares.

MATHER AND PLATT (LIMITED).—The annual return to November 13th has been filed. The nominal capital is £200,000, in £10 shares, and 15,000 have been allotted, upon each of which £9 has been paid.

ELECTRIC ORGAN COMPANY (LIMITED).—The statutory return has just been filed. The nominal capital is £110,000, in 55,000 £6 per cent. Cumulative Preference and 55,000 Ordinary £1 shares; 23,389 of the former and 2,225 of the latter class have been allotted, and 10s. per share has been called.

DUTTON AND CO. (LIMITED).—The annual return to November 11th has been filed. The capital of £60,000 is divided into 500 Preference and 5,500 Ordinary shares, of £10 each; 285 of the former and 2,810 of the latter have been taken up, and 2,200 Ordinary have been issued as fully paid to the vendors. The full amount has been called on the remaining 285 Preference and 610 Ordinary shares.

CITY NOTES.

MEMORANDA.—Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver 30 1/16d. per oz. (Nov. 28th). Consols (2¾ per cent.) 107—107⅛ for money, 107—107⅛ for account; 2½ per cent. 104½—104¾ (Nov. 28th). Stock Exchange Settling Days: Consols, Dec. 2nd; Stocks and Shares Continuation Day, Dec. 13th; Ticket Day, Dec. 14th; Pay Day, Dec. 15th. Mining Share Carry-over Day, Dec. 12th.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended November 24th were £946, against £957 in the corresponding week of 1894, a decrease of £11. The total receipts for the half-year amount to £18,562, against £18,648 for the corresponding period of 1894, a decrease of £86.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—On another page of our present issue will be found a prospectus of an issue of £100,000 Five per Cent. Debenture Stock of the above Company, at the price of £128 per cent. This is the balance of the authorised issue of £400,000, and is redeemable by the Company at £125 per cent. after December 31, 1910, by six months' notice. Subscriptions are payable on the present issue—£10 on application, £38 (including premium) on allotment, £40 on March 31st next, and £40 on June 30th next, interest on the stock (exclusive of premium) commencing from the date of allotment, and from the dates when the respective instalments become payable. Interest on this issue is payable half-yearly in July and January. Applications from existing debenture-holders will receive preferential consideration. The Debenture Stock of the Company "operates as a first charge by way of floating security upon the whole undertaking and property of the Company, exclusive of the uncalled capital for the time being, in respect of any shares hereafter created and issued, and subject as to certain tubes for telephonic purposes to a contract relating thereto with the New Telephone Company (Limited). In the event of purchase by the Local Authority the Debenture Stock and the premium payable on redemption (£25) will constitute a first charge on the purchase money received." The prospectus sets out in some detail the revenue and expenditure of the Company. Lists of subscriptions for this issue opened yesterday at 10 a.m., and closes this day (Friday), at 4 p.m., both for town and country.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).—The transfer books of this Company will be closed from December 13th to 19th inclusive, preparatory to the payment of an interim dividend of 3s. per share, or at the rate of 6 per cent. per annum, free of income tax, for the quarter ended September 30th last. The dividend is payable on December 20th.

DORMAN, LONG AND CO. (LIMITED).—The annual report of the Directors of this Company, after referring to the unexampled depression through which trade has passed, states: "One decidedly encouraging feature in the year's working is the large reduction in the cost of manufacture, due to the improvements of the last few years having come into full operation. This is seen in the fact that nearly the whole of the profit has accrued during the last six months of the financial year, although the prices then realised were lower than over the first six months. The saving effected by the expenditure during 1894 in applying electrical power to the outlying machinery was found to be so satisfactory that your Directors felt justified in a further outlay in this direction, and hence the greater part of the capital expenditure this year is for electrical machinery. Up to the present time the total amount spent on this head is about £8,000, and the saving is at the rate of £3,000 to £4,000 a year, in addition to increased efficiency."

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 24th inst. amounted to £1,067. The amount for the corresponding week last year was £913; increase, £154.

MESSRS. R. HORNSBY AND SONS (LIMITED).—In addition to the usual payment for the half-year ended September 15th, on the Preference Stock of this Company, the Directors propose a division of 4s. per share on the Ordinary shares for the year ended September 30th.

ROYAL ELECTRIC COMPANY OF MONTREAL.—During the week Messrs. Coates, Son and Co., on behalf of this Company, invited applications for £34,000 sterling Four and a-Half per Cent. First Mortgage Debentures, being the balance of an authorised total issue of $750,000 (£154,000), the first portion of which was offered for subscription in November, 1894. The authorised capital of the Company is £1,500,000, and the paid-up capital $1,000,000. The present debentures were issued at 105, and are redeemable by annual drawings at 105, or on six months' notice at 110.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—The traffic receipts for the week ended November 22nd, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,049.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861—1878.

No. 916. [Vol. XXXVI. No. 6.] FRIDAY, DECEMBER 6, 1895. PRICE SIXPENCE.

NOTES.

THE Committee, consisting of Lord Kelvin, Mr. Preece and Major CARDEW, appointed by the Board of Trade to advise it in the matter of the definition of "low pressure" has reported, and the result may be expected to be made public in the course of next week. We believe the decision arrived at will be generally acceptable.

THE members and associates of the Institution of Electrical Engineers were made acquainted on Tuesday morning, by the receipt of the balloting list for Council and officers for the year 1896, with the withdrawal of Sir DAVID SALOMONS' candidature and the substitution therefor of that of Dr. JOHN HOPKINSON, our President in 1890. The avoidance, even at the eleventh hour, of a contested election is undoubtedly a matter for general congratulation; nevertheless, members of the Institution will do well not to rest and be thankful. Had not the so-called election of Council been converted into nomination by Council the recent Presidential crisis would not have arisen. It is within the power of the members of the Institution to remedy this state of things. A simple way out of the difficulty would be to give groups of members who may consider themselves under-represented or otherwise aggrieved ample time to formulate their grievance and nominate their champion. At present a week or ten days is all that intervenes between the receipt of the Council's List and the Annual General Meeting, a period within which it is quite impossible, as the Council know full well, to make any effective counter-proposals. The Council's List should be prepared and circulated not later than the date of the first autumn meeting. Members of the Institution are amused with the appearance of free choice, but carefully deprived of any real voice. No institution deserves to thrive under such a system. The argument that it works well, notwithstanding its theoretical defects, is no longer tenable.

IN another column we publish in full a valuable report on the comparative cost of gas and electric lighting, which has recently been prepared by Mr. A. P. TROTTER at the instance of the Hastings and St. Leonards Electric Light Company. The genesis of this report is somewhat interesting. A local critic was persuading the Hastings public that electric lighting cost three times as much as gas lighting. The Electric Lighting Company, although quite ready to admit that electricity might be somewhat more expensive than gas, declined to sit quiet under this absurd allegation, and decided to call in an expert to thoroughly sift the matter, with the result that the Company has not only rebutted a groundless charge, but has shown, in a manner to be understood of all people, that under practical working conditions and at average prices electric lighting is, to put the matter in its lowest terms, no more costly than gas lighting. In arriving at this conclusion the advantages arising from the lessened cost of re-decoration, from the absence of injury to delicate goods, and from the increased healthiness and coolness of the air, have not been taken into account; not but that it would be perfectly legitimate to do so, although it is exceedingly difficult to accurately assess the money value of such advantages.

ALTHOUGH the Hastings gasophiles have good reason to regret they ever made exaggerated charges against glow lamp lighting, they may perhaps seek consolation from Mr. TROTTER'S figures with regard to the Hastings sea-front arc lights. But on closer examination we do not think they will find much wherewith to console themselves, even here. Taking the Incandescent Gas Light Company's own figures for gas consumption, candle-power, and renewals, a *naked* 500 c.p. light for one hour would cost 1·43d., with gas at 3s. a thousand, *exclusive* of cost of lamp lighters, cleaners, damages by wind and water, repairs, interest on capital outlay. The alternating arcs at Hastings, which absorb 600 true watts and give a mean light of about 500 candles, cost 1·95 per hour, *including* carbons, trimming, cleaning, repairs, and interest on capital outlay. If a more impartial source than the Incandescent Gas Light Company could be found for figures relative to gas consumption, &c.; if the items included in the cost of the arc light were also included in the cost of the incandescent gas light; and if absorption by lanterns and diminution of the luminosity of the mantles with time were taken into account, the difference of 0·52d. in favour of the "Welsbach" light would assuredly disappear. It is evident from this that the relative cost of the two systems of street lighting when good continuous-current arcs are used would be in favour of electricity.

THE simple formula given by Mr. TROTTER will enable anyone knowing the facts of the case to compute for himself the comparative cost of gas and electric lighting. At present gas enthusiasts at one end of the scale talk of electric lighting

Digitized by Google

being n times more expensive than gas lighting, n being, as a rule, an integer greater than three, and at the other end of the scale we have electrical engineers asserting that electricity is the poor man's light, implying thereby that electricity is cheaper than oil. Mr. TROTTER rightly insists on the immense importance, among the three factors that go to make up the total cost of electric lighting, of the watts per candle. We hear much about reductions in the price of the Board of Trade unit, and rejoice exceedingly thereat, little recking that a reduction from 8d. to 4d. may be, so far as the consumer is concerned, largely neutralised by the substitution of a batch of 4-watt lamps for a batch of 3-watt lamps. The careful control which many supply concerns exercise over the quality of the glow lamps used by their customers is quite to the interest of the consumer.

GAS-DRIVEN tramcars have proved such a failure in this country that the advocates of this mode of propulsion must find comfort in the fact of the Dessau gas tramcars having been run successfully for a whole year. The Dessau line was 2¾ miles in length when opened in November of last year; but it proved so popular that it was soon extended to nearly 4 miles. The present equipment includes nine 7 H.P. cars, four 10 H.P. cars and four trailers. The amount of gas actually consumed in the engines on the cars has averaged 26·6 cubic ft. per car mile, to which, however, must be added 4·46 cubic ft. used in the engines driving the gas compressors. The total consumption of gas, therefore, has averaged 31·06 cubic ft. per car mile. At 2s. 6d. per 1,000 cubic ft., this represents a cost of fuel equal to 0·932d. per car mile. If it can be shown that what has been done at Dessau can be done elsewhere and wherever there is cheap town gas, the battle between gas and electric cars will evidently have to be fought on other issues than the cost of fuel. There still remains, however, for electrical engineers the comforting fact that gas cars have had more than one genuine trial in this country, and that they have always turned out to be genuine failures.

MR. FERNANDO SANFORD is again to the fore with his hypothesis of a "Variation in Electrical Conductivity of Metallic Wires in Different Dielectrics"; and in the current number of the *Physical Review* he makes further advance in his theory. The notion that the resistance of a conductor depends on its dielectric environment has no more to do with the truth or otherwise of OHM's law than tinning the surface on copper wire has to do with the same principle of current flow. Mr. SANFORD'S hypothesis, which he conceives to involve a modification of this law, has been attacked, he says, on both theoretical and experimental grounds. We ourselves, in our issue of January 13, 1893, expressed our doubts on the latter ground. But, is it wise to attack any such hypothesis as this deductively? Are we, that is to say, so perfectly informed of the mechanism of the relationship between a conducting wire and its dielectric environment, that we can venture to deduce, without experiment, that no such variation as Mr. SANFORD supposes can take place? We prefer to believe that the existence of such a variation must stand or fall by a purely experimental test. In research work inductive evidence has always proved a safer instrument than abstract reasoning.

IN regard to our previous suggestion that the variations of resistance might have arisen from unrecognised changes in the temperature of the wire, Mr. SANFORD has prepared a table to show each observed change of resistance and the corresponding temperature variation which would account for it. The latter is of the order of 0·5 degree, and should be easily measured, so that the question narrows down to this: Do the changes of resistance, from whatever cause arising, actually take place to the extent tabulated by Mr. SANFORD? We are not prepared to pass judgment upon Mr. SANFORD'S experiments, as they stand at present; they are by no means convincing either way, but we think there is enough in them to justify further investigation of the matter. One thing seems pretty certain—namely, that if any effect there be it must be a skin effect. We would suggest, then, that the variation of resistance of conductors of equal section, but arranged to expose different amounts of surface to the dielectric, should be investigated.

AN article in a recent number of the *Electrical Engineer* of New York, from the pen of Mr. W. S. HORRY, describes a method of running arc lamps in series on an alternating-current system, to which the name of "reactance" system has been applied. We have here a modification of the old series transformer system, the transformers being replaced by choking coils, or as it is now more fashionable to call them, reactance coils, shunted by arc lamps. It will be seen at once that this loses the advantage possessed by the transformer method, of isolating each lamp from the high-pressure conductor. The simplest arrangement, in the reactance system, is a series of arc lamps with a choking coil in shunt with each lamp. In a modification, a portion of the choking coil is connected in series with the arc, the remaining portion serving as the regulating shunt. Choking coils are, and always have been, wonderfully efficient devices—on paper. "The efficiency of the device," says Mr. HORRY, "may be dismissed with a very few words. The amperes that flow through the coil are almost entirely wattless, and the whole device is exceedingly efficient." After this, it is somewhat curious to read that "the iron in the core of course gets hot, and for this reason only very little iron is employed—highly saturated." We commend this novel method of reducing iron losses to Prof. EWING!

Cable Interruptions and Repairs.—There are no cable interruptions or repairs to record.

The Coventry Electric Tramways.—As the result of the Board of Trade inspection on Friday last, a certificate has been issued, and a start has been made in running cars for general traffic.

Appointment.—We have great pleasure in announcing that the appointment of Electrician and Inspector to the Government of Cape Colony, a post which has been created by the Electric Lighting and Power Act of the present year, has been conferred on Mr. A. P. Trotter. Mr. Trotter will probably sail early in January.

Royal Society.—The following Papers were down for reading at the Royal Society yesterday:—H. C. Leake, R. Leventhorpe,

Digitized by Google

and C. S. Whitehead: "The Measurement of High Potential Difference." Prof. Ayrton, F.R.S., and W. R. Cooper: "Variations in the Electromotive Force of Clark Cells with Temperature."

Damages for Injuries Caused by the Electric Current.—The New Jersey Court of Appeals has just confirmed the verdict of a lower court by which a lineman, who lost an eye and was terribly burned by the electric current while working for the Western Union Telegraph Company, was awarded £5,000 damages.

"Aluminium and Electrolysis."—This is the title of a new monthly technical and scientific journal intended for those interested in the development and manufacture of aluminium, and in electrolysis, electricity, civil and mechanical engineering chemistry and the electro-deposition of metals. The editor is Mr. A. H. Vesey.

Royal Institution.—The following are some of the lecture arrangements before Easter: Prof. John Gray McKendrick will give six lectures (adapted to a juvenile auditory), "On Sound, Hearing and Speech" (experimentally illustrated); Lord Rayleigh will deliver six lectures on "Light," The Friday evening meetings will begin on January 17th, when a discourse will be given by Lord Rayleigh on "Argon."

Chatham.—On Thursday last week two men, in passing along the High-street, at the bottom of Clover-street, Chatham, happened to step at the same time on the lid of one of the Electric Light Company's junction boxes. Both men received a severe shock and were knocked down. The men who were knocked down were so frightened that they got up and ran away. The employés of the Company were immediately at the spot, and remedied the defect.

Electric Traction on the Dublin Southern District Tramways.—The Dublin Southern District Tramways Company have almost completed their electric system from Haddington-road to Kingstown and Dalkey. On Saturday evening last, at the invitation of Mr. J. Clifton Robinson, Managing Director of the Southern District Tramways Company, a number of people made a trial trip from the power house at Ballsbridge to Kingstown on one of the new electric cars. All along the route to Kingstown and back the progress of the visitors was greeted with enthusiastic cheers from crowds of bystanders, and when Kingstown was reached quite a big gathering welcomed the appearance of the car. Now that the line has been completed as far as Kingstown it is proposed by the Managing Director to continue these series of trial trips until everything in connection with the work has been completed before announcing the formal opening for passenger traffic. In the meantime the members and officials of the local authorities have been invited to visit the power house and to participate in the experimental journeys between Haddington-road and Kingstown.

Overhead Trolley Work.—The *Builder*, speaking of the Coventry electric tramway, says:—"The overhead work is a very good object lesson to town councillors and others, as almost every variety of method is employed. For the first part of the route the trolley wire is supported by span wires, stretched between plain tubular posts situated on each side of the street, a primitive method long since discarded by every self-respecting town in America. Next it passes Grey Friars Green, and along here the wire is suspended from single bracket standards, which form part of the railings, the effect being not unpleasing. However, span wires are soon resorted to again, the wires in many cases being fixed to rosettes bolted to houses on opposite sides of the street, special precautions being necessary to prevent the vibration of the trolley wire being communicated to the houses. There seems to have been very little attempt at either uniformity or elegance, the methods of suspending the wire proving the ingenuity of engineers to whom economy and efficiency were the only considerations. The principal lesson to be learned from this tramway is that the 'overhead work' is the most important from the citizen's point of view, and that this part of the work should be supervised by someone who has some respect for the most elementary principles of art."

Obituary.—We greatly regret to have to announce the death of Mr. Denny Lane, which took place last Friday. Mr. Lane was for many years secretary of the Cork Gas Company and Chairman of the local School of Science. He had formerly been President both of the Cork Literary and Scientific Society and of the Gas Institute. He was a man of large intellectual interests and many parts; and his loss will be felt not only among his friends in the gas industry, but also among electrical engineers. He ever took an interest in the progress of electrical science and its applications, and more particularly in that happy union of gas and electrical interests which is to be found in the gas engine station, a type of station which Mr. Lane was the first to advocate (see *The Electrician*, Vol. XXVII., p. 578). The contributions, from time to time, to our correspondence columns, also served to show that his interest in electrical matters was an active one. Mr. Denny Lane was in his 77th year.——We also regret to announce the death of Mr. John Muirhead. A share may be claimed for him in the design and introduction of the duplex system of submarine telegraphy, with which the name of his distinguished brother, Dr. Alexander Muirhead, is also associated.

Lengths of 500-Volt Arcs.—The Chicago insurance companies have recently made some experiments with a view of fixing practical distances between different parts of 500-volt switches, cut-outs, &c., with the object of avoiding the production of an arc when the circuit is broken, and also to prevent the spontaneous development of arcs should two points be too close together. We give below the figures obtained:—

Current.	Maximum distance at which the arc is produced (spontaneously).	Minimum distance at which no arc is observed (on breaking circuit).	Working distance.
	Inch.	Inch.	Inch.
10	0·25	0·25	1·0
20	0·50	0·76	2·0
30	1·20	2·00	2·7
40	2·00	2·24	3·2
50	2·24	2·52	3·5
60	3·04	3·24	3·7
70	3·04	3·40	4·0
80	3·32	3·60	4·1
90	3·56	3·84	4·4
100	3·80	4·00	4·5

Conference on Light Railways.—On Thursday last week a large gathering of gentlemen interested in the subject of light railways and their promotion by means of legislation assembled at the Westminster Palace Hotel. The chair was taken by Sir A. Rollit, M.P. Major Rasch, M.P., moved: "That this Conference heartily approves the establishing of light railways under an improved system of procedure and regulations, and with State and local aid to private enterprise; and urges Her Majesty's Government to introduce proposals for legislation on the subject at the earliest possible opportunity during the ensuing Session of Parliament." Mr. Vaughan Davies, M.P., moved: "That those present form themselves into an association, with power to add to their number, to promote the object of the previous resolution, and that Mr. J. Wallis Davies be appointed secretary." Sir J. Szlumper moved and Sir M. Lloyd seconded the appointment of a committee to examine the report of the conference called by the late Government and the Bill subsequently introduced, to formulate general detailed proposals, and to report. Mr. Squarey moved: "That the Conference be again called to consider the report of the committee, and that at such adjourned meeting a deputation be appointed to wait upon the Government in order to urge the necessity of legislation on the lines approved."

Conduit Electric Traction System at Washington, U.S.A.—The Connett conduit system, adopted by the Metropolitan Company of Washington, has attracted a good deal of attention in America, and a short description may therefore be of interest. The system employed differs from the Budapest one in the following points: The conduit is placed in the centre of the track, instead of in one of the rails; T-shaped iron conductors fixed at the top of the conduit are employed instead of angle irons arranged at the sides of the conduit, and

Digitized by Google

further a different contact mechanism has been adopted. The slot rails are Z-shaped and provided with a drip flange, which prevents the water from running down the sides of the conduit and reaching the insulators. They are braced to the grooved car rails by heavy tie rods above each yoke, and secured at the base to cast yokes placed 4½ft. apart. The conduit chamber is of concrete, and a drainage pit is provided every 300ft. to 400ft. The conductors are supported by rods screwed into porcelain insulators, which in turn are cemented on to iron cups firmly fastened to the base of the slot rails. Between the faces of the conductors a collecting plough passes. A pair of levers prevents a vertical play of the shoe, and a flat spring presses it well against the face of the T bars. A flexible conductor connects the shoe with the leads. There are four miles of double track put down at present, and though the power house is situated at one end of the line the maximum drop of potential is but 20 volts on the working pressure of 500 volts.

Engineering at Cambridge.—The report to the Senate of the Engineering Laboratory Syndicate, dated November 9, 1895, is, says *Nature*, a very satisfactory record of energetic work. The University was unable to provide more than £1,000 for the building and equipment of the laboratory, which was estimated to cost about £6,000. By steady and enthusiastic efforts Prof. Ewing and his colleagues succeeded in collecting from many sources, within and without the University, the £5,000 that were needed; and what is still more to their credit, have completed the work in hand with a small balance to the good. The continued growth of the department, in which there are now 85 students under instruction, makes a further extension of the buildings urgently necessary. A site has been provided for the purpose, but further funds are needed for construction. The workshops, never intended to be other than temporary, must soon be rebuilt and more lecture-room accommodation must be provided. The department has certainly justified its existence, and the Syndicate have proved themselves to be worthy stewards of the funds placed at their disposal. It is to be hoped that, with these guarantees that they will be well used, the needful moneys may ere long be forthcoming. The valuable services of Mr. Dalby and Mr. Lamb, the demonstrators of mechanism and engineering, in the work of organising the laboratory, are mentioned with cordial appreciation in the report. Among the donors of contributions of over £100 are the Duke of Devonshire, the late Earl of Derby, Mr. Frank McClean, and Dr. John Hopkinson, and eleven benefactors have given £100 each. Valuable donations of apparatus and of books have helped greatly towards the furnishing of the laboratory.

Glow Lamp Patent Litigation in the United States.—On November 11th the United States Supreme Court gave judgment in an action in which the fundamental Edison glow-lamp patent was challenged. The action was nominally the Consolidated Electric Light Company *v.* the McKeesport Light Company, but the real defendant was the General Electric Company and the real plaintiff the Westinghouse Electric and Manufacturing Company, which now owns the Sawyer-Man patents. The first claim of the Sawyer-Man patent, No. 317,076 of 1885 (U.S.A.) was for "an incandescing conductor for an electric lamp of carbonised *fibrous or textile material.* . . ." It was argued that the carbonised bamboo conductor used by Edison was an infringement of the claim for "carbonised fibrous or textile material." This contention did not meet with the approval of the Court of First Instance, and the Sawyer-Man patent was declared invalid; the plaintiffs thereupon appealed to the Supreme Court, which also decided against the validity of the patent. The argument of the Supreme Court was as follows:—Sawyer and Man supposed they had discovered in carbonised paper the best material for an incandescent conductor. Instead of confining themselves to carbonised paper, as they might properly have done, and in fact did in their third claim, they made a broad claim for every fibrous or textile material, when in fact an examination of over 6,000 vegetable growths showed that none of them possessed the peculiar qualities that fitted them for that purpose. Was everybody, then, precluded by this broad claim from making further investigations? Only if the patentees had discovered in fibrous and textile substances a common quality peculiarly fitting them for incandescent conductor purposes, would a broad claim such as they made have been sustainable.

Accumulator Tests in Germany.—At the laboratory of the Technical High School of Karlsruhe some tests were made a little time ago on behalf of the State Railway of Baden, with cells for a discharge rate of 1,000 amperes down to 1·8 volts, and with a guaranteed capacity of 3,000 ampere-hours. The competitors were the Accumulator Company of Hagen, Westphalia, Gottfried Hagen of Kalk, near Cologne, and the Electricitäts-Gesellschaft Gelnhausen. The tests lasted about two months, and the results are given in the following tables:—

Normal discharges at 1,000 amperes down to 1·8 volts. Guaranteed capacity 3,000 ampere-hours.

	Hagen. Amp.-hours.	Kalk. Amp.-hours.	Gelnhausen. Amp.-hours.
February 13th and 25th	3,900	2,000	3,500
March 16th	3,033	2,583	3,350
March 29th	2,500	2,333	3,250
April 20th.....	3,133	3,484	4,144
Discharge (March 15th) at 1,500 amperes.			
Potential fell to 1·8 volts in.....	88min.	72min.	100min.
Capacity (ampere-hours).....	2,175	1,800	2,500
Discharge (March 28th) at 2,000 amperes.			
After 82min. potential is.....	0·060 volt	0·280 volt	1·715 volt
Discharge (April 24th) at 4,000 amperes.			
Potential fell to 1·70 volts in ...	10min.	10min.	25min.
Capacity (ampere-hours).....	667	667	1,667
Discharge (April 25th) at 5,280 amperes.			
Potential fell to 1·66 volts in ...	5min.	5min.	15min.
Capacity (ampere-hours)	440	440	1,320
Discharge (March 19th) at 400 amperes.			
Potential fell to 1·8 volts in.....	11h. 40min.	9h. 30min.	14 hours.
Capacity (ampere-hours).....	4,667	3,800	5,600

It may be added that the "Hagen" cell is of the "Tudor" type and the "Kalk" cell is of the "grid" pattern, whilst the "Gelnhausen" are so-called "Bleistaub" (lead dust) accumulators.

Contemporary Electrical Science.—*Wiedemann's Beiblätter*, No. 10, contains a good selection of electrical abstracts from various remote sources.——M. Töpler has endeavoured to supply all the links connecting condenser oscillations with Tesla's experiments. The oscillations were transformed to lower and to higher pressures respectively. In the former case several new phenomena were observed which had not as yet been produced with electrostatic apparatus. In transforming up, all Tesla's experiments could be reproduced. Iron cores diminished the induction of these high-frequency currents.——K. A. Holmgren, of Lund, has studied the electrification of air issuing from water, and obtained differences of potential of 70 volts. He also obtained electrification by a rod dipping into water and thrown into oscillations. The vessel containing the water assumed a positive charge.——M. Reiner describes a new method of measuring the potential of a metal immersed in a liquid. The liquid is put to earth by a wet thread, and the metal connected with an electrometer. Copper in copper sulphate is positive.——A. Bartoli found that both methyl alcohol and sulphurous acid possess a certain conductivity which disappears at their critical temperature, but reappears on cooling.——Signor Majorana has investigated the formation of cuprite, Cu_2O, by the electrolysis of $CuSO_4$. When a small current is passed through dilute $CuSO_4$, acidulated with sulphuric acid, ruby-red crystals of cuprite are formed, especially when the solution is heated.——H. Luggin tested the capillary electric phenomena of molten lead covered with fused potassium and lithium bromides, and mercury covered with potassium and sodium nitrates. The capillary constants attain a maximum at lower differences of potential in iodides than in bromides, and lower in bromides than in chlorides. Helmholtz's and other theories do not agree with the facts.——E. Wiedemann describes a new kind of ray observed in spark discharges. He calls these rays discharge rays. They are not deflected by a magnet, and therein they differ from cathode rays. They more resemble the rays found in the positive light. They are characterised by the bright "thermo-luminescence" which they produce in $CaSO_4$ mixed with a little $MnSO_4$ or in the corresponding carbonates. They are absorbed by fluorspar, but not by air. Hence they are not extreme ultra-violet rays.

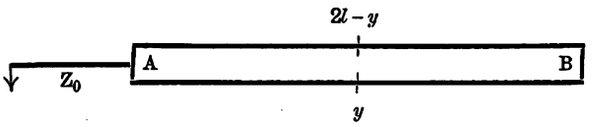
ELECTROMAGNETIC THEORY.—LXXIX.*

BY OLIVER HEAVISIDE.

(*Continued from page 113.*)

§ 313. The last examples sufficiently indicating the connection between the main solution for the cable itself and the terminal arbitraries, we may pass on to another minor matter. If the cable ends A and B are joined, either directly or through apparatus, with or without an earth connection at the same place, the two conditions expressing V/C at the terminals independently of one another are replaced by two conditions of a different kind. Some difference in the treatment is, therefore, needed. It is not great, and may be readily inferred from the preceding.

Take an explicit example. Let the length of the cable be $2l$. At B, where $x=l$, there is simple continuity, without imposed condition. At A, where $x=0$ or $2l$, there is a shunt or leak to earth. It is any sort of leak, defined by a resistance



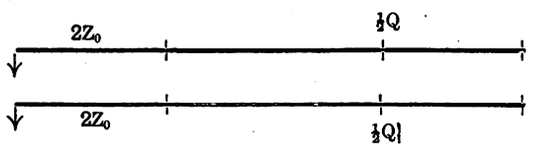
operator Z_0. We have to see how this arrangement will behave. We may consider three sorts of problems: the diffusion of a point charge initially at y, which will give, by integration, the effect of any initial state of the cable; the effect of an impressed force anywhere; and the effect of terminal energisation, when Z_0 is of a suitable kind. The last, however, may be inferred from the solution for an initial state in the cable, so we need not consider it specially.

As regards Q at y. By inspection of the above diagram, and a little thought, we may split the problem into two, of which the solutions are already known. Split Q into halves. Pair one of them with an equal charge at the corresponding point $2l-y$. Pair the other with an equal charge of the opposite sign at the corresponding point. The sum of the four charges is simply Q at y, so the solution is the same for the four as for the original Q.

Consider the positive pair alone, that is, $\frac{1}{2}$Q at y and $\frac{1}{2}$Q at $2l-y$. By symmetry they cause no current at B, and behave similarly in the upper and lower cables. At A the currents going to Z_0 are equal. They therefore unite and leak out through Z_0. Thus, each member of the positive pair discharges in its own cable in the same way as if it were insulated at B, and were earthed at A through the arrangement whose resistance operator is $2Z_0$. This case has been already considered. $2Z_0$ may be constructed by putting Z_0 in sequence with another Z_0, or in other ways.

The positive and negative pair, on the other hand, produce no potential at either A or B. There is no leakage current in Z_0, and consequently continuity of current between the upper and lower cables. So the $\frac{1}{2}$Q in the lower cable discharges as if it were earthed at A and B, and so does the $-\frac{1}{2}$Q in the upper cable. This part of the complete solution is also known. Putting these together, we obtain the complete result, and can use previous formulæ without more work.

In the case of the positive pair we have this arrangement

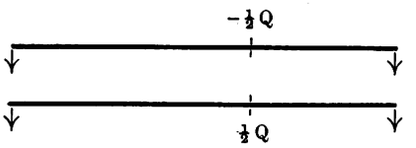


diagrammatically. Use (85), § 294. Put $Z_1=\infty$, and $2Z_0$ for Z_0, and $\frac{1}{2}$Q for Q. Then

$$v_1=\frac{(2Z_0s\cos+R\sin)sy}{(2Z_0s\sin-R\cos)sl}\cos s(l-x)\cdot\frac{sQ}{2S} \qquad (1)$$

expresses the potential at x, on the right of y, in the lower cable. Interchange x and y when $x<y$.

In the case of the positive and negative pair we have this arrangement,



and we may use the quoted formula with $Z_1=0=Z_0$, or the special formula (18), § 267. The result is that

$$w_1=-\frac{\sin sy}{\sin sl}\sin s(l-x)\cdot\frac{sQ}{2S} \qquad (2)$$

expresses the potential at x on the right of y in the lower cable.

In the upper cables the potentials are the same at corresponding points in the first case, and their negatives in the second. Uniting the two formulæ, we see that

$$V_1=v_1+w_1 \qquad (3)$$

is the potential at x in the lower cable, when greater than y, and the same with x and y interchanged when x is less than y. The same formula is valid all the way from y to $x=2l$, as we may see by altering x to $2l-x$, and observing that v_1 is unchanged, whilst v_2 is negatived.

The conversion to Fourier series is to be done as usual by the expansion theorem. Doing it in the most simple case of $Z_0=R_0$, a constant, we obtain

$$V=\frac{Q}{Sl}\Sigma\sin sy\sin sx\,\epsilon^{pt}+\frac{Q}{Sl}\Sigma\frac{(2R_0s\cos+R\sin)sy\cdot\cos s(l-x)}{2R_0s\cos sl+(R+2R_0/l)\sin sl}\epsilon^{pt}, \qquad (4)$$

which is now valid on both sides of y. In the first summation $\sin sl=0$. In the second, we have

$$\tan sl=R/2R_0s \qquad (5)$$

for determinantal equation. The result for the upper line need not be written separately, being the same formula.

When we make $R_0=\infty$, we have the two cables connected together without external constraint. We then reduce the above to Fourier's periodic formula. Notice the way the constant term arises. The last equation has a very small root when R_0 is big, and the corresponding p is very small. In the limit the root is zero, and the result is a constant term showing that the final effect is a uniform state of potential in the complete cable.

§ 314. If we should not notice that the problem admitted of splitting into two in the above way, we would proceed thus. Start with Q at y. This is an impulsive external source of current $pQ=h$, as explained before. Then let

$$V_1=\epsilon^{qx}F+\epsilon^{-qx}G, \qquad V_2=\epsilon^{qx}H+\epsilon^{-qx}I, \qquad (6)$$

where V_1 is the potential at x when on the right side of Q, and V_2 when on the left side. There are four time functions to be determined, and four conditions which find them.

(1) Continuity of potential at A makes

$$H+I=\epsilon^{2ql}F+\epsilon^{-2ql}G. \qquad (7)$$

(2) Continuity of potential at y makes

$$\epsilon^{qy}F+\epsilon^{-qy}G=\epsilon^{qy}H+\epsilon^{-qy}I. \qquad (8)$$

(3) Discontinuity in the current at A makes

$$V=Z_0(C_1-C_2), \qquad (9)$$

at $x=0$. Or

$$\frac{H+I}{Z_0}=-\frac{q}{R}\left\{\epsilon^{2ql}F-\epsilon^{-2ql}G-H+I\right\}. \qquad (10)$$

(4) Discontinuity in the current at y (regarding h as any function of the time) makes

$$h=C_1-C_2=pQ, \qquad (11)$$

at $x=y$. Or

$$pQ=-\frac{q}{R}\left\{\epsilon^{qy}F-\epsilon^{-qy}G-\epsilon^{qy}H+\epsilon^{-qy}I\right\}. \qquad (12)$$

* This series of articles is a portion of Vol. II. of Mr. Heaviside's work on "Electromagnetic Theory." All rights of reproduction are reserved.

Digitized by Google

These four conditions determine the time functions and make, finally,

$$V_2 = \frac{\frac{R}{2Z_0}\sin s(2l-y)\sin sx + s\sin sl\cos s(l+x-y)}{\sin sl\left(\sin sl - \frac{R}{2Z_0 s}\cos sl\right)}\,\frac{Q}{2S}, \quad (13)$$

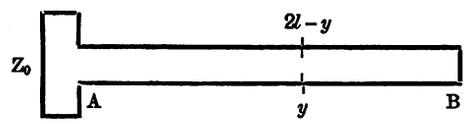
$$V_1 = V_2 + \sin s(x-y)\,.\,sQ/S. \quad (14)$$

That the determinantal equation splits into two distinct equations is shown by the denominator in (13), and it may be readily shown that the operator in (13) may be represented as the sum of two operators, one having the denominator $\sin sl$, the other the bracketed part of the denominator in (13). One of these partial operators produces v_1 and v_2, the other w_1 and w_2. The expanded solution in Fourier series is the same as before got, of course.

The difference between V_1 and V_2 is operationally exhibited in equation (14). It is equivalent to exchanging y and x in the preceding formula, and taking the difference. But this difference has no existence in the Fourier series. We can see that by putting the extra part of (14) in the numerator, when it becomes multiplied by the denominator, and therefore gives zero terms when the expansion theorem is applied. We also see the same by observing that only even powers of p are involved in the extra operator in (14). But this extra operator is not of no moment in general. If, instead of the impulsive source of current pQ, we have h, any function of the time, the solutions to right and left of the source are got by writing h/p for Q in (13), (14), and the difference between the forms of V_1 and V_2 cannot be neglected in general; for example, when h is simply periodic, and the algebrisation is effected by $p^2 = -n^2$.

When we have an impressed force e at y instead of h or pQ, we can treat the matter similarly by either of the above ways, noting now that C is continuous and V discontinuous at y. Since $\frac{1}{2}e$ at y, together with $\pm\frac{1}{2}e$ at the corresponding point in the upper cable, produce zero current at B, or else zero potential, with similar effects at A, we see that the problem splits into two connected simpler cases.

§ 315. In the above, Z_0 produced a discontinuity in the current, though none in the potential. But if we introduce Z_0 in circuit with the double cable, and have no earth connection, it is the current that is continuous, and the potential discontinuous at A. The question arises whether the problem



admits of splitting. It clearly does when Z_0 is a resistance, because equal similar charges at y and $2l-y$ will produce no current either at B or A, that is, in Z_0; whilst equal unlike charges will produce no potential at B or in the middle of Z_0. So the problem splits into two, in one of which there is insulation at both A and B, whilst in the other there is earth at B, and earth through resistance $\frac{1}{2}R_0$ at A.

That a similar split takes place when Z_0 is a condenser is also evident on consideration. The same may be said of any simple electrical arrangement which is divisible into similar halves. But it is not immediately evident that a split is possible when Z_0 is any electrical arrangement, which may have no sort of symmetry with respect to the cable terminals. It is sufficient to think of a coil and a condenser in sequence. Given a charge at y, and an equal charge at the corresponding point. If it be said that if the charges are unlike there is zero potential in the middle of Z_0, it may be asked, Where is the middle? The condenser and coil are not comparable in the way suggested. At the same time, the property must be true in a certain sense, because the combination of condenser and coil behaves to external voltage as a single whole. The same is true of any regular combination. It may be symbolised by an operator, without entering into its detailed structure in the form of coils and condensers.

The proper interpretation is to substitute for the combination symbolised by Z_0 two combinations in sequence, each symbolised by $\frac{1}{2}Z_0$. This is easily done. The condenser and coil may be replaced by two condensers and two coils, all in sequence. Then one of the new condensers and one of the new coils in sequence makes $\frac{1}{2}Z_0$, provided the resistance, inductance, and elastance of the original coil and condenser are all halved. Similarly as regards the remaining new condenser and coil. Z_0 has now a middle in reality, as well as in imagination. A similar process is applicable to any combination. So, without actually doing it in detail, we may say that equal unlike charges at y and the corresponding point redistribute themselves in the same way as if earth were on at B, and earth on in the middle of Z_0; or, without speaking of the middle, as if we substitute for Z_0 two arrangements each equivalent to $\frac{1}{2}Z_0$, and then put on earth between them.

So let there be a charge $\frac{1}{2}Q$ at y and $\frac{1}{2}Q$ at $2l-y$. They move as if the ends A, B were insulated. If v_1 is the resulting potential at x on the right of y, we have

$$v_1 = \frac{\cos sy}{\sin sl}\cos s(l-x)\,.\,\frac{sQ}{2S}, \quad (15)$$

either by (85), § 294, with $Z_0 = \infty = Z_1$ and $\frac{1}{2}Q$ instead of Q; or by the elementary theory in § 269.

Also, if w_1 is the potential at x on the right of y due to $\frac{1}{2}Q$ at y and $-\frac{1}{2}Q$ at $2l-y$, we have

$$w_1 = -\frac{(2R\sin + Z_0 s\cos)sy}{(2R\sin + Z_0 s\cos)sl}\sin s(l-x).\frac{sQ}{2S}, \quad (16)$$

by the same formula (85), with $Z_1 = 0$, $\frac{1}{2}Z_0$ instead of Z_0, and $\frac{1}{2}Q$ instead of Q.

It follows that if there is initially only Q at y, the resulting potential V_1 at x on the right of y is

$$V_1 = v_1 + w_1. \quad (17)$$

The expansions of v_1 and w_1 are to be effected as usual. I have given so many examples that it is unnecessary to exhibit the special expansions required here. The expansion theorem (30) is very easy to remember and to apply when required. On the other hand, the operational formulæ are much easier to manipulate. Note in the present case that there is a constant term in V_1. It arises from v_1, and its value is $Q/2Sl$, the mean potential which is finally existent because there is no leak anywhere.

§ 316. But as the above reasoning about the splitting of Z_0 may not be wholly convincing, we may justify its accuracy by a direct investigation. Say there is initially Q at y. Let

$$V_1 = \cos sx\,.\,F + \sin sx\,.\,G \quad (18)$$

at x on the right of y, that is, from y up to $x = 2l$. Also, let

$$V_2 = V_1 + \sin s(x-y)\,.\,K \quad (19)$$

on the left of y, V_1 meaning the expression in the previous equation.

The condition of continuity of the potential at y is already satisfied. We also require

$$pQ = C_1 - C_2 \quad (20)$$

at y, C_1 and C_2 being the currents corresponding to V_1 and V_2, obtained by the operation $-(d/dx)/R$. Doing this, we get

$$pQ = sK/R, \quad (21)$$

making
$$C_2 = C_1 - \cos s(x-y)\,.\,pQ, \quad (22)$$

and
$$V_2 = V_1 - \sin s(x-y)\,.\,\frac{sQ}{S}. \quad (23)$$

There are now only the two time functions F, G to be found. The condition of continuity of current at the ends of Z_0 gives

$$\frac{s}{R}(\sin 2sl\,.\,F - \cos 2sl\,.\,G) = -\frac{Gs}{R} - \cos syp\,.\,Q; \quad (24)$$

and the condition

$$V_1 - V_2 = Z_0 C, \quad (25)$$

which is the equation of voltage for Z_0, gives

$$\cos 2sl\,.\,F + \sin 2sl\,.\,G - F - \sin sy\,.\,\frac{sQ}{S} = Z_0\left(-\frac{Gs}{R} - \cos sy\,.\,pQ\right). \quad (26)$$

Digitized by Google

These equations find F and G by the usual algebraical work. Using the results in (18) and (23), we obtain

$$V_1 = \frac{2\sin sl\cos s(l-x+y)+(Z_0 s/R)\cos sy\cos s(2l-x)}{\sin sl(2\sin sl+\cos sl\ .\ Z_0 s/R)}\ \frac{sQ}{2S} \quad (27)$$

$$V_2 = V_1 - \sin s(x-y)\ .\ sQ/S. \quad (28)$$

These are the complete operational solutions without initial splitting. We see that the determinantal equation does split into two, giving

$$\sin sl = 0, \quad \text{and} \quad \tan sl = -Z_0 s/2R, \quad (29)$$

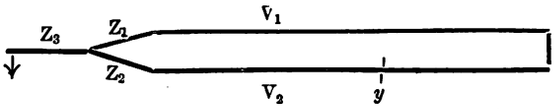
proving definitely the validity of the previous reasoning.

Now, if we expand the above V_1 by the expansion theorem, attending only to $\sin sl = 0$, we shall obtain the expansion of the v_1 in (15). And if we expand according to the other condition in (29) we shall obtain the expansion of w_1 in (16). Thus $V_1 = v_1 + w_1$, when in the fully expanded form.

But the equivalence is also true in the operational form. To prove this, add together the v_1 and w_1 of (15) and (16), uniting the two fractions to make one with a denominator which is the product of the former ones. The result is (27), as required.

The expanded formula for V_2 is the same as for V_1. The complete solution for the whole cable from $x=0$ to $2l$ is therefore given by a single Fourier series, although it is separable into two of different types. The same is therefore true for any initial state of the cable. The reason is that there is not (except at the initial moment of the instantaneous introduction of the charge) any sort of constraint all the way from $x=0$ to $2l$. If there were, say a constraint at $x=z$, we should want two distinct Fourier series, one for each side of z. The determinantal equation would be the same, but there would be a break in the normal systems.

§ 317. We have done one case involving a discontinuity in the current, and another involving a discontinuity in the potential. But in general both will be discontinuous. Let, for example, the connection between $x=0$ and $x=2l$ be made through $Z_1 + Z_2$ in sequence, with a shunt to earth put on at



their junction. Let V_0 be the potential at the junction. Then we have these voltage equations to satisfy:—

$$V_1 - V_0 = Z_1 C_1, \quad V_0 - V_2 = Z_2 C_2, \quad V_0 = Z_3(C_1 - C_2); \quad (30)$$

and therefore have the two terminal conditions

$$V_1 = (Z_1 + Z_3)C_1 - Z_3 C_2, \quad (31)$$

$$V_2 = Z_3 C_1 - (Z_2 + Z_3)C_2. \quad (32)$$

In these equations V_1 and C_1 mean the potential and current at $x=2l$; V_2 and C_2 those at $x=0$.

If, then, there is an initial charge Q at y, we can obtain the operational solution by means of equations (18) and (23) above, applied to (31), (32), to determine F and G. The result is, as before, a single Fourier series to represent both V_1 and V_2. It sometimes divides into two sets. For example, if Z_1 and Z_2 are equivalent, we get symmetry.

(To be continued.)

LIQUID FUEL.

From time to time we have had occasion to call the attention of our readers to the utilisation of petroleum residue, creosote, tar, and other heavy liquids, as fuel. The value of these combustibles for steam raising has long been recognised in countries where they are cheap and where coal is dear; but their application to this use in this country was not made prominent until the adoption of locomotives burning liquid fuel, by the Great Eastern Railway Company; and the attention of electrical engineers in particular was called to this mode of raising steam by Mr. R. E. Crompton, in his Paper on "The Cost of Electric Energy" (*Proc. Inst. E. E.*, Vol. XXIII.). The accompanying illustrations show the construction of the latest pattern of liquid fuel injector, as used for boiler firing on the Holden system. Fig. 1 shows the general arrangement of the injectors in a Babcock-Wilcox boiler; and Figs. 2 and 3 give details of the injector itself. Before we describe these particularly it will be well to summarise the main facts connected with the use of liquid fuel.

In this country liquid fuels are either the by-products of industrial processes, and therefore liable to considerable fluctuation of price, or they have to be imported from considerable distances, usually Southern Russia or America, and are therefore expensive. To the former class belong creosote, green oil, paraffin refuse, tar, &c.; to the latter, astatki and petroleum residuum, the one the Russian and the other the American petroleum refuse. After having occasion to go into the matter very carefully, we have no hesitation in saying that, as a main source of heat for steam raising in stationary boilers, in this country, none of these fuels can compete with coal. Petroleum refuse in bulk costs from 2d. to 3½d. per gallon; creosote about the same, or slightly less; tar about half this figure. The theoretical evaporative power of astatki is about 17·5lb. of water from and at 212°F.; good coal will readily give a *practical* evaporative efficiency of 9lb. or 10lb. of water from and at 212°F. Therefore, if astatki be only twice as dear as coal, per ton, even perfect evaporation, with no loss of heat of combustion, would not make astatki pay. In the majority of places in this country astatki would be more than twice the price of coal, per ton. It must not be forgotten, however, that besides the relative costs of the fuels, other elements of expense are affected. The handling of liquid fuel is cheaper than the handling of coal by human stokers, though it is doubtful if it is cheaper than the mechanical handling of coal. And on the other hand, liquid fuel requires generally an expenditure of steam in a heating coil, to keep it sufficiently fluid, as well as an even larger consumption of steam in the fuel injector.

We have made these remarks, not from any desire to deprecate the use of liquid fuel in electric supply stations, but to give force to the statement we are now about to make, that the proper function of this class of fuel is to act as an auxiliary in coal-fired boilers. The use of liquid fuel is susceptible of a much finer and more regular adjustment than even the best automatic coal stoker. The gentlest readjustment of the throttle valve actuating the injector suffices to raise or lower the boiler pressure a pound or so, and to keep it steadily at the altered figure. That is one advantage. Another point in its favour is the astonishing rapidity with which the steaming rate of a boiler may be increased a very considerable amount. With coal firing there will always be an appreciable interval between the extra firing and the extra steaming; and in that interval the sudden rise in the load may fatigue the boilers and drop the pressure to a serious extent. It may be that a fog has suddenly taken lodging over the area of supply. With oil firing by means of spray injectors no such lag or interval of delay exists; andwhen the regulator valves are turned on full, the firebox is simultaneously filled with flame capable of making enough steam to take on the extra duty at once. Thus its ease and fineness of adjustment, and its promptness, are the chief merits of liquid fuel firing which commend it to the central station engineer. And to obtain these things it is often worth while to burn a little more expensive fuel on occasion, keeping to coal for the main work. To cite one or two actual examples: Mr. Crompton has made practical trial of oil fuel for the boilers of the Kensington and Knightsbridge supply station, as well as in the Chelmsford supply station; and the system has also been in use at the Sardinia-street station of the Metropolitan Electric Supply Company. Oil firing is only used for forcing the boilers over the heaviest load. In the case of a Root's boiler, from which 700 H.P. was obtained by coal firing, an extra 300 H.P. could quickly be obtained by turning on the oil-fuel injectors.

Mr. Crompton has tried every available form of liquid fuel. He condemns the use of coal tar; but is satisfied with astatki, provided it can be obtained for 2d. a gallon, the price he pays for it at present. Naturally, the fuel purchased will depend on the state of the market; and very often it will pay to mix several liquid fuels and burn them together. At the present

Digitized by Google

time, at the Kensington and Knightsbridge Station, oil gas tar, a by-product in the manufacture of Pintch's oil gas, is largely used, at a cost of about 2d. per gallon.

A glance at Fig. 1 will enable the reader to see that the Holden injector can be fitted to a boiler front with very little trouble or expense. Where oil alone is to be burned, the grate will be covered with firebrick, chalk or other refractory material; but where coal is to be burned as well, the furnace will not be altered. An aperture about 4in. diameter is cut above each fire door, in such a manner as not to interfere with the coal firing; and an injector is fitted in an inclined position so as to direct the blast away from the furnace crown. Fuel is fed to the injectors from a tank, which should be placed in such a position that the injectors have to lift the fuel a few feet. The fuel in this tank is usually kept sufficiently fluid by means of a steam coil. Overhead tanks have been found to

work with less satisfaction than tanks below the boiler level. The injector, A, in Fig. 2, receives fuel through the regulator valve, B, and live steam through the pipe immediately behind it (to the left, in the drawing). In the furnace side of the injector, there are three orifices, set in horizontal line, in the middle of a circular steam ring jet. The two outer orifices form the fuel jets; and from the inner orifice, as well as from the ring jet, blasts of steam are projected against the liquid fuel, the ring jet directing the steam convergently upon the fuel. Thus is the liquid fuel completely "atomised" or sprayed into very finely-divided particles, the combustion of which takes place readily. The effect of this mode of combustion is beneficial in every way. It is unaccompanied by the formation of residual matter or smoke; and, owing to the fact that the furnace is completely filled with flame, while no flame impinges locally on the heating surfaces, no injury is done to the boiler plates by the rapid rate of steaming.

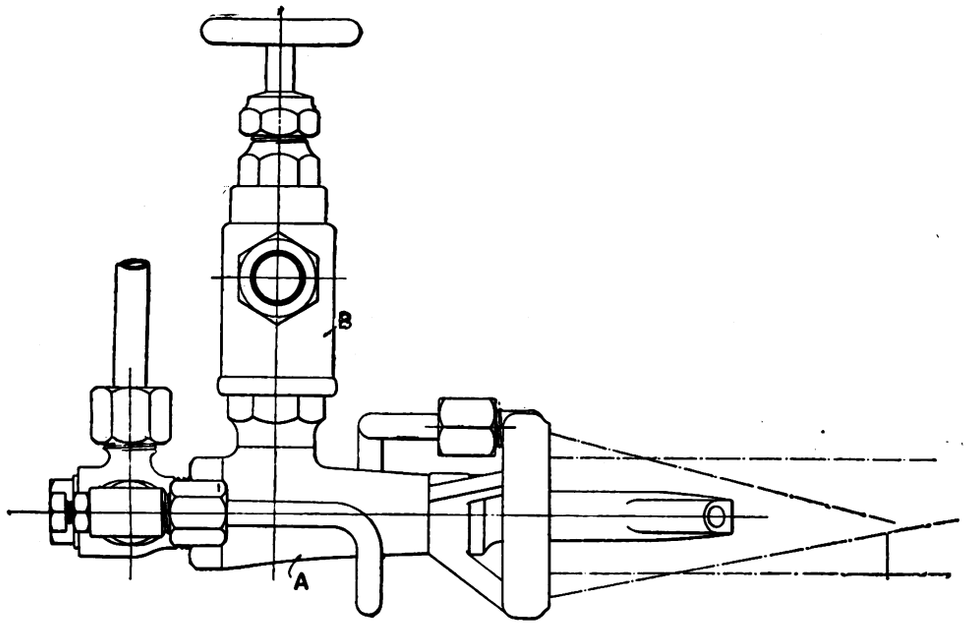

FIG. 2.

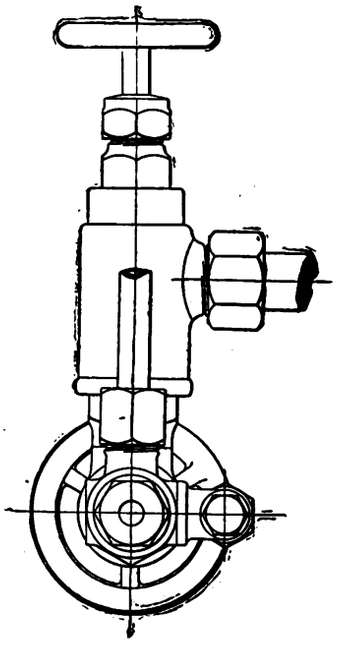

FIG. 3.

The Holden system of liquid fuel firing is adapted to boilers by Messrs. Taite and Carlton, to which firm we are indebted for the illustrations accompanying this article.

POWER DEVELOPMENT AT NIAGARA.

The electrical development of the power available at Niagara Falls still continues. The oldest power project at the Falls is the hydraulic canal, an open waterway which diverts a portion of the water of the upper river from its natural channel and conducts it to a basin situated a short distance, 300ft., back from the high bank of the lower river, from which basin it is conducted by flumes to the penstocks of the turbines of the mills now operated there. For the past few years the owners of this canal, the Niagara Falls Hydraulic Power and Manufacturing Company, have been expending large amounts of money in widening their possession in order to obtain a greater water supply and thus increase their power facilities. The work of enlarging the canal is now practically completed, and the Company have prepared plans and commenced work on what is destined to be a power house and plant of considerable magnitude.

This new power house is to be located on the sloping bank, at the edge of the water, in the river below the Falls. To prepare for the construction of the building it was necessary to clear the site of broken rock boulders. In some places the mass was from 75ft. to 100ft. deep. When the *débris* was all removed a substantial stratum of sandstone was found, and on this the new power house will be erected.

The building will be of stone, 60ft. long and 100ft. wide, but ultimately, as demand for power makes it necessary, the length of the building will be extended. For this plant water will be carried in an open canal from the basin before referred to to a forebay 30ft. wide and 22ft. deep, which is now in process of construction between the edge of the high bank and the basin. From this forebay, penstocks of flange steel, 8ft. in diameter, will conduct the water down the slope, a distance of 210ft., to the power house at the edge of the water in the lower river. These penstocks will lead from the forebay vertically about 135ft. to the top of the bank slope, thence down this slope to the side of the power station next to the bank, thus making the total length of the 8ft. pipes about 240ft. Pipes 10ft. in diameter will run horizontally into the building and be suspended over the tail race leading from the station. The thickness of the steel in these pipes will be $\frac{15}{16}$ths of an inch. All horizontal joints will be butt-strapped and held with three rows of rivets on each side. The cross seams will all be double riveted.

At the start, four turbine wheels of the horizontal type, having a capacity of about 7,000 H.P., will be located on the first floor of the station. Each turbine will be fed from a separate penstock, and will work under a head of 210ft. From the horizontal portion of the penstock the water will pass up through 60in. valves to the water wheels, which will be supported upon iron beams stiffened by braces built into the side of the tail race. The turbines will be mounted on horizontal shafts of the double-discharge design. They will be fitted with runners 74in. in diameter, made of bronze metal, and equipped with balanced gates. They will be so designed that the wheel runners are balanced by the equal discharge of water on each side, thus avoiding the use of end thrusts on the shafts. They will set in cases 11ft. in diameter, made of the best heavy plate steel and double riveted. The feeder pipe connections to these large cases will be on the bottoms of the same, being riveted directly to the 5ft. hydraulic cylinder valve, all of which valves will be connected to the main feeder pipe, which will be 10ft. in diameter, and will occupy space under the turbines between the foundation walls. Down each side of the main feeder pipe draft tubes from the turbines will pass, connecting with the tail water, which will be set at a distance of 27ft. from the centre of the turbine shaft. The shaft will be of wrought iron, carried in adjustable ring oiling bearings and mounted on heavy cast-iron bridge trees.

The first four wheels for this station will be built by James Leffel and Co., of Springfield, O. Three of them are guaranteed to develop 1,700 H.P., under a head of 205ft., which is the minimum head estimated as obtainable, and to run at a speed of 250 revolutions per minute. As the ordinary head used will be from 210ft. to 215ft., the power from these wheels, it is expected, will be from 1,800 H.P. to 2,000 H.P. each. These three wheels will be connected to six electrical generators, two to each wheel, the electrical power to be used by the Pittsburg Reduction Company, manufacturers of aluminium, in a new factory to be built on the top of the high bank. The fourth wheel will be connected to two 560-kilowatt generators, and will make 300 revolutions a minute. By this means a 500-volt current for street railway or general power purposes will be obtained. The work is in charge of W. C. Johnson, chief engineer of the Company.

THE BEHAVIOUR OF TRANSFORMERS UNDER THE INFLUENCE OF ALTERNATING CURRENTS OF DIFFERENT WAVE FORMS.*

BY DR. G. ROESSLER.

(Continued from page 153.)

The variation of the potential and current curves with the loaded transformer is given in Figs. 14 to 17. In these curves the absolute values of the ordinates are not given; they may be obtained from the tables given at the end.

Each of the Figs. 14 to 17 shows the variation of the primary current J_1, and potential difference Ep_1, and of the secondary potential difference Ep_2. Since the load on the transformer is absorbed by glow lamps, the curve of the secondary current J_2 is of the same character as that of Ep_2. The curve of J_2 is therefore not separately drawn. Figs. 16 and 17 give the curves, with both machines, for the fully-loaded transformer $J_2=4$ A, Figs. 14 and 15 those for a load of $J_2=\frac{1}{2}$ A.

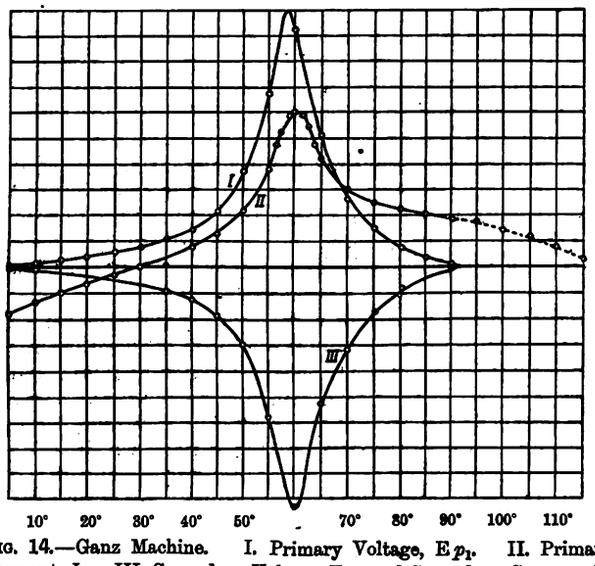

FIG. 14.—Ganz Machine. I. Primary Voltage, Ep_1. II. Primary Current, J_1. III. Secondary Voltage, Ep_2, and Secondary Current, J_2. $\sqrt{M(J_2^2)}=\frac{1}{2}$ A.

The figures show that the Ep_1 and Ep_2 curves are nearly the same shape for all loads of the transformer, and are symmetrical about the axis, and that the curve of J_1, for increasing transformer loads, approximates more nearly in shape and phase to Ep_1. The first effect is due to the small potential drop on the winding of the transformer, hence Ep_1 approaches equality to $n_1 \frac{dN}{dt}$, and $Ep_2 = n_2 \frac{dN}{dt}$, hence $\frac{Ep_1}{Ep_2}$ is constant. These calculations hold with equal accuracy, whatever the form of the primary potential difference curve.

* "Das Verhalten von Transformatoren unter den Einflusse von Wechselströmen verschiedenen periodischen Verlaufs." A Paper read at the third annual meeting of the Verband Deutscher Electrotechniker, Munich July 6, 1895.

The observed variation in J_1 can be explained as follows:—If, as here, $\sqrt{M(Ep_1^2)}$, and thus also $M(Ep_1)$, are kept constant, the mean value of the magnetisation of the iron must remain constant

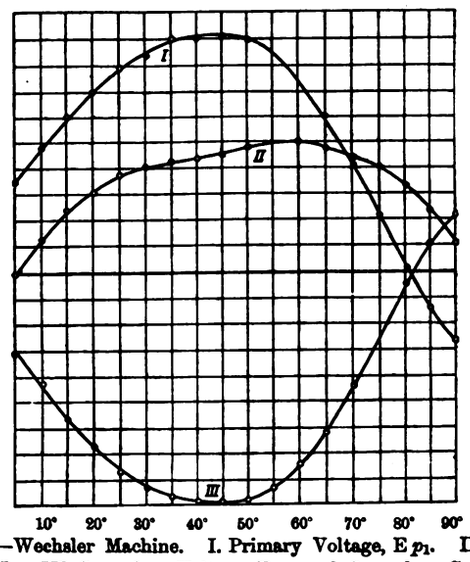

FIG. 15.—Wechsler Machine. I. Primary Voltage, Ep_1. II. Primary Current, J_1. III. Secondary Voltage, Ep_2, and Secondary Current, J_2. $\sqrt{M(J_2^2)}=\frac{1}{2}$ A.

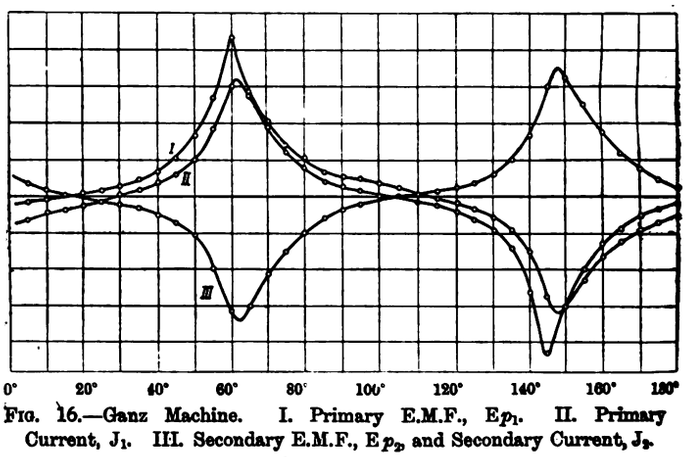

FIG. 16.—Ganz Machine. I. Primary E.M.F., Ep_1. II. Primary Current, J_1. III. Secondary E.M.F., Ep_2, and Secondary Current, J_2. $\sqrt{M(J_2^2)}=4$ A.

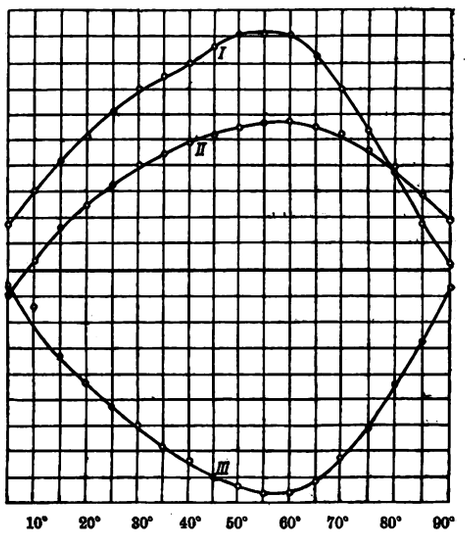

FIG. 17.—Wechsler Machine. I. Primary Voltage, Ep_1. II. Primary Current, J_1. III. Secondary Voltage, Ep_2, and Secondary Current, J_2. $\sqrt{M(J_2^2)}=4$ A.

for all loads on the transformer. Hence the total magnetising force, which is the algebraic sum of the magnetising forces due to both windings, must remain the same. For increasing

Digitized by Google

values of J_2, this is only possible if the curves J_1 and J_2 have the same form and opposite phase, so that their magnetising forces must be subtracted at each instant, and if J_1 increases simultaneously with J_2. But since also J_2 has the same form and phase as $E p_2$, and $E p_2$ is in opposite phase to $E p_1$, J_1 must approximate more nearly to $E p_1$ in shape and phase as the load increases. If the curves J_1 and J_2 were always of the same shape and in opposite phase, and also of the same shape as the primary current curve for no-load J_0, then the conditions for constant magnetising force for all loads would be given by the equation

$$n_1 \sqrt{M(J_1^2)} - n_2 \sqrt{M(J_2^2)} = n \sqrt{M(J_0^2)},$$

$$\text{or } \sqrt{M(J_1^2)} = \sqrt{M(J_0^2)} + \frac{n_2}{n_1} \sqrt{M(J_2^2)}.^*$$

As Fig. 7 shows, the relation between the primary current and the secondary current is almost linear. Only at small loads does $\sqrt{M(J_1^2)}$ increase more slowly than $\sqrt{M(J_2^2)}$, this would be explained by J_1 approaching opposite phase to J_2, since the decrease of magnetisation is effected by increasing J_2, without $\sqrt{M(J_1^2)}$ increasing in the same proportion as at high loads.

These remarks concerning the shapes of the curves assist in explaining the great difference found in the primary power, current, efficiency and regulation.

Differences in Power Taken Up and Efficiency.

The primary power A_1 of a loaded transformer is divided into the secondary output A_2, and the power lost. These quantities are independent of the shapes of the potential difference and current curves in two points, the loss in the copper winding $J_1^2 w_1 + J_2^2 w_2$, and the iron loss, which is composed of hysteresis and eddy currents. The power lost in hysteresis per cycle per cubic centimetre of iron is given by the factor $\frac{1}{4\pi}$ times an area of the closed hysteresis curve having B_{max} as the highest induction in the iron. If V is the volume of iron, ν the periodicity of the current, and f the area of the hysteresis curve, the loss in the iron $= V \nu \frac{1}{4\pi} f$ and the total power lost in the transformer, neglecting eddy-current loss

$$A_1 - A_2 = J_1^2 w_1 + J_2^2 w_2 + V \nu \frac{1}{4\pi} f.$$

The determination of the power lost in hysteresis is very difficult if it has to be obtained by planimetering the hysteresis curve. It is well known that Steinmetz, from a large number of hysteresis measurements in iron, has obtained the result that the area of the curve can be given by the formula

$$f = \eta B^{1.6}_{max},$$

where η is a constant depending on the material, whose value for average soft iron is 0·002. This result is confirmed by the measurements of Ewing and others; they do not put it forward as a natural law, but as an empirical rule of sufficient accuracy for technical purposes.

To the power lost through hysteresis must be added the loss by eddies. If, in a closed circuit of resistance w_1, an E.M.F. E is induced, the power lost is $\frac{E^2}{w}$. Here E equals the secondary alteration of the lines of force cut by the circuit, and this is dependent on the quantities $+B_{max}$ and $-B_{max}$, between which the magnetisation alters. Hence the power lost in eddies is proportional to $\nu^2 B^2_{max}$, and can be expressed in the form $V \xi \nu^2 B^2_{max}$, where ξ is a constant which depends on the material, and the thickness of the plates and wire. On this account, Steinmetz gives as the expression for the total loss in the iron

$$\mathfrak{C} = V (\nu \eta B^{1.6}_{max} + \nu^2 \xi B^2_{max}).$$

In this formula it is shown that the iron loss only depends on the shape of the curve so far as this affects the value of B_{max}, and that the loss is smaller, the smaller B_{max}.

In the present case it is found that the peaked curve gives smaller iron loss than flat. The conclusion that this difference is typical for all peaked and flat curves is then settled if it is shown that flat curves for the same R.M.S. of the primary potential difference always have greater values of B_{max} than pointed curves.

Relations between B_{max} and the Shape of the Curve $E p_1$.

The simple mean of the potential difference $M(E p_1)$, which is found by planimetering the potential difference curve, and finding the height of a rectangle of equal area, stands in constant relation to B_{max}, since it is given by the equation

$$E p_1 = J_1 w_1 + n_1 \frac{dN}{dt},$$

the quantity $J_1 w_1$ being small in comparison with the other, so that one can take for the mean, with close approximation,

$$M(E p_1) = M\left(\frac{dN}{dt} n_1\right).$$

But, from the principles of induction, the mean E.M.F. induced in either winding equals the mean variation of the flux; hence we have the following: During each period the flux increases from $-N_{max}$ to $+N_{max}$, and falls from $+N_{max}$ to $-N_{max}$, the total variation is thus $4 N_{max}$; for ν periods per second, the mean variation in induction $= \nu 4 N_{max}$, and in the n_1 turns the mean induced E.M.F. $= 4 n_1 \nu N_{max}$.

Hence we have the equation

$$M(E p_1) = 4 n_1 \nu N_{max} = 4 n_1 \nu s B_{max}^*$$

as the expression for the relation between B_{max} and $M(E p_1)$. From this we are enabled to calculate from the R.M.S. of the potential difference, $\sqrt{M(E p_1^2)}$, the value of B_{max}, if we know the ratio,

$$\frac{M(E p_1)}{\sqrt{M(E p_1^2)}} = c.$$

By comparison of these ratios

$$\sqrt{M(E p_1^2)} = \frac{4 n_1 \nu s B_{max}}{c},$$

and

$$B_{max} = \frac{c \sqrt{M(E p_1^2)}}{4 n_1 \nu s}.$$

From these relations we can easily find the power lost in the iron for different values of the primary potential difference $\sqrt{M(E p_1^2)}$, and can calculate the curve $\mathfrak{C} = f(B_{max})$. *If it is correct that the iron loss only depends upon B_{max}, we ought to get the same curve $\mathfrak{C} = f(B_{max})$ from the most different potential difference curves.* This conclusion was proved in the present case. The measurements were so conducted that varying pressures were supplied to the transformer, from both machines, and measured with a Cardew voltmeter, the secondary of the transformer being open. At the same time, the power A_0 of the transformer was measured by a wattmeter, and the current by a dynamometer. If A_0 and J_0 are the corrected values, the loss by hysteresis in the transformer core

$$\mathfrak{C} = A_0 - J_0^2 w_1.$$

From $\sqrt{M(E p_1^2)}$, B_{max} was calculated from the above equation where, for the Ganz machine, $c = 0{\cdot}590$ and, for the Wechsler machine, $c = 0{\cdot}841$, from former researches. The periodicity was, during this investigation, 40·57. For the Ganz machine

$$B_{max} = \frac{c \sqrt{M(E p_1^2)}}{4 n_1 \nu s} = \frac{0{\cdot}590 \sqrt{M(E p_1^2)}}{4 \times 132 \times 40{\cdot}57 \times 20{\cdot}19},$$

and for the Wechsler machine

$$B_{max} = \frac{0{\cdot}841}{4 \times 132 \times 40{\cdot}57 \times 20{\cdot}19} \sqrt{M(E p_1^2)}.$$

The results were the following:—

Table VI.

In Fig. 18 the two curves of iron loss as a function of B_{max} are given, the upper curve for the Ganz machine, the lower for the Wechsler machine. The two curves lie near each other but never come quite together; the iron loss when using the Ganz machine is 13 per cent. greater than with the Wechsler machine. This difference can be understood by supposing that Steinmetz's formula does not explain the variations with sufficient accuracy. On closer consideration one finds that the loss by eddies can be arrived at in another way. If the instantaneous value of the E.M.F. in a circuit in the iron core be at any moment E, the power lost

* For good modern transformers with closed magnetic circuit this equation holds with greater accuracy than for the old one under consideration.

* This formula holds generally for all curves with single maximum.

† The potential difference in this case could not be increased, since the maximum allowable excitation of the machine was attained.

Digitized by Google

by eddies is proportional to $M(E^2)$. But the R.M.S. of the induced E.M.F. in the primary $=\frac{4\,n_1\,s\,\nu\,B_{max}}{c}$; hence $M(E^2)$ is proportional to $\frac{\nu^2 B^2_{max}}{c^2}$, and the loss by eddy current is thus $\xi'\frac{\nu^2 B^2_{max}}{c^2}$.

This formula differs from Steinmetz's in the introduction of the factor $\frac{1}{c^2}$, which is absent in Steinmetz's. Since c depends on the form of the potential difference curve, it cannot be included in the constant ξ.

If we put $\nu=40$, $\eta=0{\cdot}002$, and $\xi=2\times10^{-7}$ in Steinmetz's formula, we find that for values of B_{max} between 0 and 10,000 the loss by eddies is about the one-seventh part, or 14·3 per cent. of the hysteresis loss. For an alteration of c from 0·59 to 0·84, c^2 alters from 0·35 to 0·7. Thus the eddy-current loss in the transformer, with the Ganz measurements, would be twice as great, or about 14 per cent. more than when using the Wechsler machine. The observed difference of 13 per cent. is, therefore, completely explained.

The practical calculation of the power lost in the core of a transformer is given most exactly by the formula

$$C=\nu\eta B^{1\cdot6}_{max}+\frac{\xi'\nu^2 B^2_{max}}{c^2}.$$

If an extreme case is considered, large errors may arise by the use of the simple formula of Steinmetz, or of a curve $T=f(\mathfrak{E}_{max})$, which neglects the influence of the form of the potential-difference curve on the eddy-current loss.

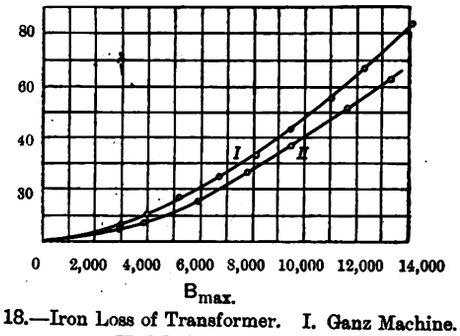

FIG. 18.—Iron Loss of Transformer. I. Ganz Machine. II. Wechsler Machine.

Theoretically it is interesting to note that the true eddy-current loss

$$C_2=\xi'\frac{\nu^2 B^2_{max}}{c^2},$$

and also

$$\sqrt{M(E p_1^2)}=\frac{4\,n_1\,\nu\,s B^2_{max}}{c};$$

hence

$$\mathfrak{E}_2=\frac{\xi'}{16\,n_1{}^2}M(E p_1)^2,$$

which only depends on the R.M.S of the primary potential difference and for constant values of this, is independent of the form of the curve, since the last equation does not contain c.

The loss by hysteresis thus becomes

$$=\nu\eta\left(\frac{c\sqrt{M(E p_1)^2}}{4\,n_1\,\nu\,s}\right)^{1\cdot6},$$

which contains c.

The differences in the total iron loss for different potential difference curves arise simply from variations in the hysteresis loss, which arise from the alteration of c.

In the case where the eddy current loss is much greater than the hysteresis loss, no great alteration of iron loss would result from variation of the shape of the potential difference curve. In all practical cases, however, the loss in the iron is always smaller, if c decreases. The general explanation of the observed fact that peaked potential difference curves give smaller iron losses reduces to the statement that peaked curves have a smaller value of c than flat curves.

Influence of the Curve Shape on the Value of "c."

The quantity c is known, entirely, from the geometrical form of the potential difference curve; for the sine curve, it is well known $c=0{\cdot}9$. In general it is clear that if a part of the ordinates of a curve are much greater than the rest, these greater ordinates increase the R.M.S. more than the simple mean. This is illustrated by the following example: Let there be (Fig. 19) the nth part of the abscissa a_1 representing a half-period, having ordinates of a height h. Then the simple mean is $\frac{h}{n}$, the mean of the square $\frac{h^2}{n}$, and the R.M.S. $\frac{h}{\sqrt{n}}$; therefore $c=\frac{1}{\sqrt{n}}$, *i.e.*, the smaller the part of the whole abscissæ upon which the ordinates stand, the smaller the value of c. This conclusion holds when the remaining ordinates are not vanishingly small, and shows that for peaked curves c is smaller than with flat curves. How c varies with increasing acuteness of the curve is shown in the following example. In Fig. 20 let the parabolas A_1, A_2, A_3 be parts of the potential difference curve, symmetrical about the axis. If the equations to the parabolas

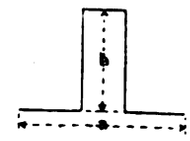

FIG. 19.

are in general $y=x^n$, the most pointed are those in which n is greatest. In general the simple mean is found thus:—

$$\frac{1}{a}\int_0^a y\,dx=\frac{1}{a}\int_0^a x^n dx=\frac{a^{n+1}}{(n+1)a}=\frac{a^n}{n+1}.$$

The mean of the square

$$=\frac{1}{a}\int_0^a y^2\,dx=\frac{1}{a}\int_0^a x^{2n}\,dx=\frac{a^{2n+1}}{(2n+1)a}=\frac{a^{2n}}{2n+1},$$

and the root of the last

$$=\frac{a^n}{\sqrt{2n+1}};$$

hence $c=\frac{\sqrt{2n+1}}{n+1}$, which is smaller as n increases. For $n=1$, $c=0{\cdot}865$; $n=2$, $c=0{\cdot}745$; $n=3$, $c=0{\cdot}660$.

Thus, for an unloaded transformer, it is easily seen that the iron loss for peaked potential curves is the smallest. This result

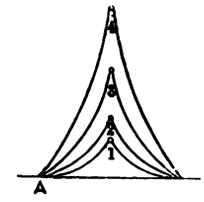

FIG. 20.

also holds for the loaded transformer, if the R.M.S. potential difference is kept constant for all loads, since the loss only depends on the value of the primary potential. The results of the above measurements are also generally applicable.

The frequently-made statement that the form of the potential difference curve has no influence on the efficiency of a transformer, becomes explicable, since where these observations have been made

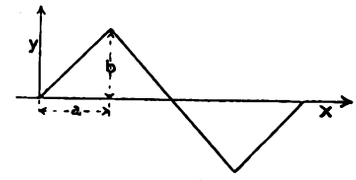

FIG. 21.

with different machines the quantity c had almost the same value. In fact, a sine curve can be very greatly distorted without perceptibly affecting the value of c. If the curve, for example, is made like Fig. 21, then, if $y=cx$ is the equation to the line,

$$M(y)=\frac{c\,a}{2}.$$

$$M(y^2)=\frac{1}{a}\int_0^a y^2\,dx=\frac{1}{a}\int_0^a c^2 x^2\,dx=\frac{c^2 a^2}{3}.$$

$$\sqrt{M\,y^2}=\frac{c\,a}{\sqrt{3}},$$

$$c=\frac{M(y)}{\sqrt{M(y^2)}}=\frac{\sqrt{3}}{2}=0{\cdot}866.$$

Digitized by Google

If the curve has the form shown in Fig. 22, we have

$$M\,y = \frac{\frac{b}{2} + b}{2} = \frac{3}{4}\,b\,;$$

$$M\,(y^2) = \frac{\frac{b^2}{3} + b^2}{2} = \frac{2}{3}\,b^2,$$

$$\sqrt{M\,(y^2)} = \sqrt{\tfrac{2}{3}}\,b,$$

$$c = \frac{M\,(y)}{\sqrt{M\,(y^2)}} = \frac{3}{8}\sqrt{6} = 0{\cdot}919.$$

These values of c differ very little from 0 9. The alternators which are used in practice with transformers always give potential

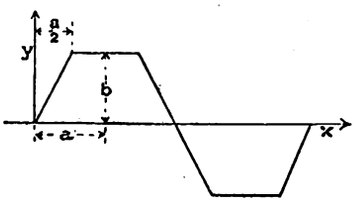

Fig. 22.

difference curves which lie between the curves given in Figs. 21 and 22, so that it is obvious that the calculations assuming $c = 0{\cdot}9$ would yield results very near the truth.

(To be concluded).

NOTE ON TINFOIL GRATING AS A DETECTOR FOR ELECTRIC WAVES.*

BY PROF. T. MIZUNO.

Much interested by Herr E. Aschkinass' experiments described in his Paper read before the Physical Society of Berlin, I have been induced to repeat them. How far my results confirm his and how far they differ from them, will be seen from this Note, in which I also give a few tests of the sensibility of tinfoil grating as a detector of electric waves, and an account of some experiments to determine the nature of its action.

I prepared by gratings by first coating a flat wooden block with tinfoil and then cutting on it a number of fine parallel slits with a sharp knife (*see* Fig. 1). A and B are binding screws which are fixed in the block and facilitate the connection of the grating with a Wheatstone's bridge.

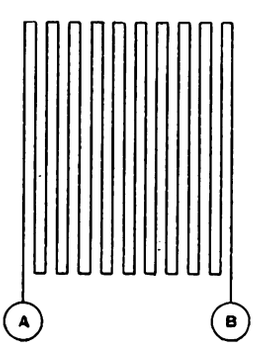

Fig. 1.

The particulars of the two gratings chiefly used in my experiments were as follows:—(1) Rectangular in form, 3·5cm. by 5·1cm., total number of lines 97, and the resistance nearly 130 ohms. (2) Also rectangular, 3 5cm. by 4·4cm., the number of lines 118, and the resistance nearly 232 ohms.

My primary vibrator was a brass cylinder 3cm. in diameter and 26cm. in length, its surface interrupted midway along its length by a spark gap, and its ends furnished with brass spheres 4cm. in diameter forming the poles. The wave length of the electric waves produced was ascertained to be about 60cm. The vibrator was placed in the focal line of a wooden parabolic cylinder coated inside with tinfoil, whose height was 76cm., depth 21cm., and focal length 12cm. My resonator is very simple in construction and has been found very convenient in my other researches on electric waves. It is merely a rectangular strip of tinfoil, 0·8cm. in breadth and 60cm. (30cm. in some case) in length, with a gap in the middle, which is so fine that resonance sparks can easily pass across.

I will now describe some experiments with the view of showing to what extent metallic gratings can screen the action of electric waves.

Experiment 1.

A wooden board, on which were pasted two parallel tinfoil strips, 33cm. in length and at a distance of 9·7cm. from one another, was set up vertically in front of the parabolic cylinder at a distance of about 30cm. from the vibrator. The grating No. 1 was brought behind the board, and after exposure for about half a minute to electric waves, its resistance was examined by a Wheatstone's bridge. The results obtained were as follows:—

Experiment.	Initial resistance.	Final resistance.	Decrease of resistance.
1	129·7 ohms.	123·5 ohms.	6·2 ohms.
2	129·7 „	123·4 „	6·3 „
3	129·9 „	123·6 „	6·3 „

As Herr Aschkinass mentions, the resistance of the grating once diminished by the action of electric waves could be restored almost to its original value by tapping it. In this experiment, resonance sparks could be discovered behind the board by means of my tinfoil resonator.

Experiment 2.

Next, a third strip was pasted on the board, half-way between the other two and the experiment repeated. The results were:—

Experiment.	Initial resistance.	Final resistance.	Decrease of resistance.
1	129·7	123·7	6·0
2	129·8	123·8	6·0
3	130·0	123·5	6·5

Here, the resonance sparks behind the board were very feeble.

Experiment 3.

Two more strips were then added bisecting the spaces between those in the previous experiment.

Experiment.	Initial resistance.	Final resistance.	Decrease of resistance.
1	129·8	125·8	4·0
2	129·8	125·6	4·2
3	130·1	125·7	4·4

The resonator behind the board gave no sparks in this case.

Experiment 4.

Next, a grating, rectangular in form, 27cm. in length and 22cm. in breadth, was made, the average distance between two consecutive strips being about 0·6cm. Placing this grating in a vertical position in front of the parabola and bringing the grating just behind it, the following changes in resistance were observed:—

Experiment.	Initial resistance.	Final resistance.	Decrease of resistance.
1	129·7	123·7	6·0
2	129·1	124·1	5·0
3	129·2	123·5	5 7

Experiment 5.

Substituting for the above grating a large wire grating, 1·7 metres in the side and with consecutive wires 3cm. apart, I have found the changes of resistance as follows:—

Experiment.	Initial resistance.	Final resistance.	Decrease of resistance.
1	129·9	126·5	3·4 ∥
2	129·9	123·4	6·5 ⊥
3	129 9	126·7	3·2 ∥
4	130·2	124·5	5·7 ⊥
5	130·4	127·0	3·4 ∥
6	130·3	124·1	6·2 ⊥

* From the *Journal* of the College of Science, Imperial University, Tokio, Japan, Vol. IX., Part I., 1895.

Digitized by Google

The signs in the last column of the above table denote the orientations of the wire grating according as the wires were placed parallel or perpendicular to the primary vibrator. The results show how different are the effects of polarised waves on my tinfoil grating. The experiments have shown also how sensitive the tinfoil grating is to the action of electric waves in comparison with my rectilinear tinfoil resonator, because I have found that whereas the former has shown a large amount of change in resistance the latter gave no perceptible resonance spark.

Experiment 6.

I now placed my tinfoil grating within a glass bell-jar which was covered with tinfoil strips. I found that even in this case the change of resistance was distinctly perceptible. Thus :—

Experiment.	Initial resistance.	Final resistance.	Decrease of resistance.
1	129·7	125·0	4·7
2	129·9	125·7	4·2
3	129·9	125·6	4·3

This result may be taken to indicate how imperfect would be the protection of an ordinary metallic gauze against powerful electric oscillations.

Experiment 7.

A circular copper plate 30cm. in diameter was vertically suspended in front of the vibrator. My tinfoil grating placed behind the plate at a distance of about 12cm. from it, showed the following changes in resistance :—

Experiment.	Initial resistance.	Final resistance.	Decrease of resistance.
1	129·1	121·0	8·1
2	129·3	122·3	7·0
3	129·4	122·0	7·4

Next, the distance between the plate and the grating was diminished to 2·5cm. The changes were as follows :—

Experiment.	Initial resistance.	Final resistance.	Decrease of resistance.
1	129·3	123·0	6·3
2	129·0	123·2	5·8
3	129·5	123·0	6·5

The difference between the results of this and those of the last experiment I am inclined to ascribe to the diffraction effects of electric waves caused by the plate.

Experiment 8.

A rectangular wooden board, 69cm. in length and 14cm. in breadth, was coated all over with tinfoil. When it was held vertically with the longer edges parallel to the primary oscillations, the resistance of my tinfoil grating placed behind it showed no change, but when the edges were placed perpendicular to the primary oscillations, I found :—

Experiment.	Initial resistance.	Final resistance.	Decrease of resistance.
1	130·0	127·0	3·0
2	130·8	127·7	3·1
3	131·4	127·8	3·6

This shows that the intensity of the diffraction effect depends on the extension of the tinfoil board with respect to the direction of of the primary oscillations.

Experiment 9.

A parabolic cylinder exactly similar to the one mentioned before was placed against the latter, at a distance of about 1·5 metre. So that their focal lines should be parallel. My tinfoil grating No. 2 was held in the focal line of the second parabolic cylinder and tested, thus :—

Experiment.	Initial resistance.	Final resistance.	Decrease of resistance.
1	229·9	219·0	10·9
2	229·9	219·7	10·2
3	229·9	219·6	10·3

Taking away the cylinder, I found :—

Experiment.	Initial resistance.	Final resistance.	Decrease of resistance.
1	230·0	227·6	2·4
2	230·0	228·0	2·0

Experiment 10.

In this experiment, my tinfoil grating No. 2 was placed just in front of a metallic plate—that is to say, near the node of the stationary electric waves produced by the plate, with the following results :—

Experiment.	Initial resistance.	Final resistance.	Decrease of resistance.
1	222·0	200·0	22·0
2	227·0	206·0	21·0
3	228·0	206·5	21·5

Taking away the plate, I found :—

Experiment.	Initial resistance.	Final resistance.	Decrease of resistance.
1	227·2	184·7	42·5
2	225·7	184·5	41·2

Experiment 11.

In order to examine whether the orientation of the tinfoil grating with respect to the primary oscillations has an influence or none on the change of its resistance, the following observations were carried out.

(1) With the grating No. 1.

Experiment.	Initial resistance.	Final resistance.	Decrease of resistance.
1	132·4	125·0	7·4 ⊥
2	132·2	125·5	6·7 ∥
3	132·4	125·2	7·2 ⊥
4	132·4	126·4	6·0 ∥
5	132·5	125·5	7·0 ⊥
6	132·7	126·5	6·2 ∥

(2) With the grating No. 2.

Experiment.	Initial resistance.	Final resistance.	Decrease of resistance.
1	232·0	189·9	42·1 ⊥
2	232·0	193·0	39·0 ∥
3	232·0	187·0	45·0 ⊥
4	232·0	196·0	36·0 ∥
5	232·4	183·2	49·2 ⊥
6	232·2	194·5	37·7 ∥

The signs in the last column indicate the direction of the tinfoil strips of the gratings with respect to that of the primary oscillations. Thus, the answer may be taken as positive.

Experiment 12.

Lastly I performed some experiments to decide the question whether the change of resistance under consideration is a molecular change as in a selenium cell or simply a mechanical one. For this purpose I prepared very carefully another tinfoil grating with a much wider space between the strips. It was rectangular, 7cm. in length and 6cm. in breadth, the total number of fine strips being 51 (*see* Fig. 2). The resistance of the grating thus prepared was 209 ohms. Now exposing this grating to the action of electric waves, I did not find the least sign of change in its resistance, except a very small one due perhaps to the heating effect. The experiment was, of course, tried several times and also on different occasions, but never with positive result. Here I wish also to notice that although I tried the experiment with fine German-silver wire and also fine iron-wire gratings, I could never find any decided effect due to the action of electric waves on them.

Conclusions.

1. It is certain that the change of resistance of the tinfoil grating is due to the action of electric waves. So far as the electric discharges in the primary spark-gap are oscillatory, they have an effect on the grating, but if not oscillatory, none.

Digitized by Google

2. Inasmuch as where my rectilinear tinfoil resonator fails the tinfoil grating shows the presence of electric waves, the latter must be regarded as far more efficient than the former as a detector of electric waves. Even a single spark, if oscillatory, is sufficient to produce a large effect on the grating. I would here call attention to the fact that the change in resistance of one and the same grating observed on different days during the course of my research differed in amount. This is certainly due to the conditions of the spark-gap, and consequently the intensity of the primary oscillations, and also somewhat to the time of exposure.

3. The sensibility of gratings may, up to certain limits, be increased by increasing the fineness and closeness of the strips. For, of my two gratings which are nearly equal in their dimensions but greatly different in the number of strips, the first gave the maximum change of about 6 per cent., while the second gave about 19 per cent.

4. The phenomenon under consideration may not be molecular, and so far as my experiments go, seems to be purely mechanical. Slits cut in tinfoil with a knife, however sharp they may be, surely have margins which are zigzag. I imagine that the action of

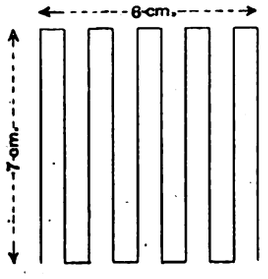

FIG. 2.

electric waves may consist in giving impulses to several strips of tinfoil so as to let the leaflets on the margins come in contact with one another and thus cause a diminution of the total resistance of the grating. Especially the fact that the spacing of the strips should have so large an influence as to reduce the effect almost to nothing seems to me to favour the above supposition. Also the fact that the change of resistance depends upon the orientation of the strips seems to point in the same direction. Still another fact which is equally important from the above point of view is that the resistance of the tinfoil grating once diminished by an exposure to the action of electric waves can be restored nearly to the original va'ue by tapping the grating. It may be pointed out that Prof. Minchin's experiment * on the action of electromagnetic radiation on films containing metallic powders may stand in close connection with the present subject.

PHYSICAL SOCIETY.

At a special meeting held on November 22, 1895, Capt. W. de W. Abney (President) in the chair, the following resolution, with reference to the Articles of Association, was passed :—In Article 33 to strike out the words "by the payment of £10 in one sum," and in place of this to insert the words "the composition fee shall be, for every member who shall not have paid 10 annual subscriptions, 15 times the amount of the annual subscription payable by such member, and for any member who shall have already paid 10 or more annual subscriptions, 10 times the amount of the annual subscription payable by such member."

The ordinary meeting then took place.

Dr. G. JOHNSTONE STONEY exhibited a print of Profs. Runge and Paschen's photograph of the spectrum of the gas obtained from clevite, together with a diagram illustrating the manner in which these observers have arranged *all* the lines obtained in two sets, each set containing three series of lines. Dr. Stoney also drew attention to the resemblance between each of these sets of three series of lines and the similar triple series obtained in the case of the metals of Mendelejeff's first group.

Mr. R. APPLEYARD read a Note on

"The Action of Sulphur Vapour on Copper."

When a copper wire is exposed for some time to the action of sulphur vapour it becomes entirely converted into sulphide of copper, and it is found that there is a fine axial hole running down the rod of sulphide formed. Rods of copper of square section cut from a block of copper after exposure to the action of sulphur vapour also exhibited the axial hole, the rod of sulphide formed being of circular cross-section. In every case the diameter of the rod of sulphide formed is about twice that of the original rod of copper. Delta metal was found to be unacted upon by the sulphur vapour.

* *Phil. Mag.*, p. 90, 1894.

Mr. APPLEYARD then read a Paper on

"A Direct-Reading Platinum Thermometer."

This form of platinum thermometer has been devised with the view of determining the temperature of the dielectrics employed in some experiments on the variation of the electrical resistance of dielectrics with temperature. The thermometers consist of six platinum coils, each of about 7 ohms resistance, attached to thick copper leads. A slide-wire Wheatstone's bridge is employed to measure the resistance. The stretched wire is 3 metres long, and the moving contact so arranged that it is impossible to damage the wire. The auxiliary coils used in connection with the bridge are immersed in a bath of paraffin oil, the temperature of which is maintained constant, and a little above that of the air, by means of a glow lamp immersed in the oil.

Mr. APPLEYARD also read a historical Note on

"Resistance and its Change with Temperature,"

in which he showed that the earliest measurements of the variation of resistance with temperature were made by Leutz in 1833. Some experiments on this subject made by Davy are also referred to, and some of these experiments were repeated before the Society.

Mr. TROTTER said he agreed with the author, that the "reserve of precision" at our disposal on account of the delicacy of some of the modern instruments ought to be made use of to facilitate the rapid performance of many measurements where the utmost accuracy is not necessary. He had the impression that platinum-silver was not now considered the best material for use as the bridge wire.

Mr. H. F. BURSTALL explained the differences between the temperature as measured on the mercury, air and platinum thermometers. At a temperature of about 40deg. the platinum thermometer read about 0·4deg. and the mercury thermometer about 0·1deg. below the air thermometer. Prof. Callendar had obtained measurements of temperature correct to within 0·1deg. by using a Weston voltmeter and an ordinary Wheatstone bridge, the variations of resistance, and hence the temperature being read directly from the deflections on the voltmeter.

Mr. RHODES thought that, except where extreme accuracy was necessary, the mercury thermometer was very much more convenient than the platinum thermometer.

Mr. BURSTALL said the great convenience of the platinum thermometer lay in the fact that the scale would be read at a distance of many yards from the point where the temperature was being measured, and hence it could be used in many places where it would be impossible to read a mercury thermometer.

Mr. BLAKESLEY considered that the author was somewhat bold to state that it was for general purposes never necessary to measure temperature to nearer than one-tenth of a degree.

The author having replied, the Society adjourned till the 13th of December.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, December 6th.

INSTITUTION OF JUNIOR ENGINEERS.

8 p.m. Meeting at the Westminster Palace Hotel. Paper to be read: "Considerations with respect to Water, Gas, and Electric Mains, &c., in connection with the Formation of Urban Roads and Footways," by J. Julian.

MONDAY, December 9th.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture II.: "Mechanical Road Carriages," by W. Worby Beaumont.

TUESDAY, December 10th.

SELF-PROPELLED TRAFFIC ASSOCIATION.

3 p.m. Meeting at Cannon-street Hotel to consider the advisability of forming an Association. Sir David Salomons, Bart., will preside.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Discussion on Messrs. Arnold and Wrightson's Paper on "The Physical Properties of Iron and Steel."

NORTHERN SOCIETY OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary Meeting at the Palatine Hotel, Hunt's Bank, Manchester. Paper to be read: "Test of a Colliery Hauling, Pumping and Lighting Installation," by C. H. Lees.

WEDNESDAY, December 11th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Adjourned Discussion on Mr. Cunynghame's Paper on "Locomotive Carriages for Common Roads."

THURSDAY, December 12th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Annual General Meeting, to be followed by a Discussion on the following Papers: (1) "The Electric Wiring Question," by F. Bathurst; (2) "Concentric Wiring," by Sam. Mavor.

MODERN ELECTROLYTIC ALKALI PROCESSES.

The development of most enterprises takes place by a series of advances and retreats, the former predominating to give a nett onward pace, and the history of industrial electrolysis shows no exception to this rule. Just now a period of advance is in prospect, if reports and other indications may be believed. The character of that advance may be judged by the accounts of the meetings of two companies recorded in a recent issue. Seeing that the processes used by these two associations are, in a sense, rivals, something may be learnt as to the standing of the infant industry, which they both hope to extend and make profitable, by instituting a comparison between their respective methods and progress, actual and probable.

The Electro-Chemical Company (Limited), which held its second annual meeting on November 5th at St. Helens, is stated to be now at work producing caustic soda and bleaching powder, although the output of these commodities is not announced. It is reasonable to suppose that the quantity is small at present, as no drop in price has taken place, and indeed it is the happy position of the Company to be able to obtain the highest rates fixed by the United Alkali Company, which controls the market. When the make approaches the 20,000 tons said to represent the capacity of the plant, a distinct influence on the ruling price may be reasonably anticipated. The Aluminium Company (Limited), which is interested in the Castner-Kellner process, had more to say of patent sales and negotiations than of the production of alkali and chlorine. The Castner-Kellner process, formed by the amalgamation of cognate patents, is, however, of such recent date that it can scarcely be expected to begin a manufacturing and dividend-earning existence yet awhile. The news that Continental and American manufacturers have bought certain of the foreign patents, and are about to work them, is good and encouraging, having regard to the status of the firms concerned; but the fact that the two largest producers of alkali in this country have held aloof is not without significance.

Digitized by Google

Regarding the technical advantages and drawbacks of the two processes, much might be said did space permit of a detailed criticism. A few salient points may, however, be touched upon without unduly exceeding our customary bounds. Thus it is interesting to note that in the case of these two latter-day manifestations of electro-chemical invention, the interest (and conflict) centres round the cathode, once the negelected and despised Cinderella of every electrolytic cell. In the Electro-Chemical Company's apparatus the use of an iron cathode, such as has generally been employed in similar cases, has been retained, and its simplicity and cheapness are justly extolled. Parenthetically it may be remarked that the use of oxide of copper to oxidise hydrogen at the cathode appears to be abandoned, or, at least, there is little mention of it now. For the Castner-Kellner cell, mercury, functioning at once as a cathode and as a means of transmitting one of the products of decomposition (sodium) outside the cell proper, has been chosen, and its advantages have been fully impressed upon the receptive. A few years ago no one pretended to have the smallest interest in the cathode of a cell for making chlorine and caustic soda; it was either a new diaphragm or an artfully-contrived anode which claimed the public notice and the public's money. All that is for the moment changed; it is the anode which is neglected, and as for the diaphragm, it is as often as not absorbed by the triumphant cathode—a veritable pluralist. We should be, perhaps, too sanguine were we to hope that the difficulties which in early days constantly arose from the behaviour of the anode and diaphragm, have become mere obsolete traditional bogies; nevertheless, it may be reasonably deduced that such difficulties are not so pressing and importunate as they used to be, and that consequently some time and inventiveness are set free for the solving of less vital, but still important, problems. Given a cathode of mercury, as in the Castner-Kellner process, plentiful fault may be found with it. That it is heavy and costly is not to be denied; that, to secure the mobility on which its effectiveness as cathode and carrier depends, the use of rocking cells is requisite, cannot be gainsaid; but to brand it as a deadly insidious poison, when employed in this manner, seems to us a little far-fetched. Lives spent in an atmosphere of mercury vapour are neither pleasant nor healthy, but deplorable consequences need not be predicted for those whose occupations lead them to work in rooms wherein any necessary number of tons of the liquid metal are reposing in well-covered tanks. Leakages of chlorine, relatively inconsiderable, are far more likely to be troublesome and dangerous, though even under the worst conceivable working conditions the neighbourhood of a number of decomposing cells would be paradisiacal in comparison with the vicinity of a bleaching-powder chamber undergoing the process of emptying. The gallant Chairman of the Electro-Chemical Company remarked, with much justice, that the impressionable character of mercury was well shown by the use of the metal for barometers and thermometers; but, unhappily, he failed to trace a connection between this circumstance and the subtle toxic effects which he seemed to expect from the cathodes of the Castner-Kellner cell. Excogitation of the matter has failed to help us, for it leads irresistibly to the conclusion that if such a connection exists, then glycerine and air are poisonous in the extreme, and this view is difficult of reconciliation with recorded observations apparently authentic and reliable. Notwithstanding this confusion of ideas, however, the Chairman of the Electro-Chemical Company certainly made one good point when he alluded to the necessity of machinery for driving the oscillating tanks, as an undesirable feature of the Castner-Kellner process. Assuredly it is undesirable, the more so that the cost of plant per unit of product is inevitably high in all electrolytic processes for making alkali and chlorine which have been hitherto worked out. To justify extra expenditure on this item, some great gain in efficiency must be shown, and then choice between two processes, otherwise similar, becomes a mere matter of arithmetic. Reverting a moment to the question of the mercury cathode, it may be mentioned that figures are cited, appearing elsewhere in these pages, which effectually dispose of the belief that any tangible quantity of the metal can find its way into the systems of the operatives.

But the anode, though temporarily neglected, is not a negligible quantity. In most processes that have made any headway their devisers have adopted the use of carbon, in some form, for the anode. But one carbon differeth from another in refractoriness, and the ultimate method of selection must be a happy blend of experiment and experience. Information, if not considered too valuable to publish, as to the result of the trials on a considerable scale which have taken place freely within the last three or four years, would be in the highest degree interesting and important. Some data must now exist for determining the probable life of an anode of a given class of carbon, and calculation of the expenditure involved in renewals should have become possible. Again, the feasibility of using graphitic carbon prepared by the aid of the electric furnace is worthy of careful consideration. In fine, the anode is yet to be improved, and its amelioration should afford at least as much scope for ingenuity as does the devising of novel forms of cathode. Whatever the direction in which inventors may for the moment be working, one thing is certain, namely, that never before have two or more schemes, all possessing certain elements of advantage, if not of success, been brought to a point where there is excellent reason to think they may be tried thoroughly and on a scale which can leave no doubt as to their ultimate status. The present epoch is in this respect noteworthy.

REVIEW.

Cavi Telegrafici Sottomarini—Costruzione, Posa, Riparazione. Dall Ing. E. Jona. (Submarine Telegraph Cables—Construction, Laying, and Repairing. By E. Jona, Electrical Engineer.) (Milan: Ulrico Hoepli.)

A long-felt want has been supplied to telegraphists and students of electrical science in Italy by the publication of Signor Jona's work. An occasional spasmodic effort has indeed been made to enrich the very meagre scientific literature of that country dealing with the subject in question, but no regular attempt has hitherto been made to fill up the hiatus between the various text-books—all following the same beaten track—and the principles evolved out of modern practice. The handy little volume before us contains a collection of facts regarding submarine cables which, we may almost say, are not to be found in any two separate works, even in English. In a short preface the author acknowledges that he has drawn a great deal of his information from all the handbooks and treatises of electrical science extant, but in the compilation of such a work this necessity becomes self-evident.

The volume consists of 338 pages of closely-written matter, 188 clearly-drawn cuts, a map, and an index. It is divided into eight parts, the first of which is devoted to a review of the earliest attempts to lay submarine cables until the successful completion of the first Atlantic cable in 1866, and to the industry of submarine cable manufacture in Italy. In 1886 the firm of Pirelli and Co., of Milan, which for some years previously had been engaged in the manufacture of insulated telegraph wire, opened a large establishment in the naval

Digitized by Google

seaport town of Spezia, especially devoted to the manufacture of submarine telegraph cables, and shortly afterwards obtained an order for some dozen short cables to connect certain islands with the continent, and also a proposal for renewing and maintaining the old Otranto-Valona cable laid in 1864 by Henley and Co. Before, however, the firm could execute this order, it was necessary to procure a properly-equipped cable-ship, eventually supplied by Messrs. Thompson of Sunderland. This vessel, now the "Città di Milano," closely resembles the "Electra" belonging to the Eastern Telegraph Company, and although owned by Pirelli, she practically forms part of the Italian Navy. Since 1887 the firm has made and laid some 900 knots of cable for Italy, and about 400 knots for the Spanish Government. The chapter closes with a table of all the cables of the world.

Part II. is entirely devoted to the construction of cables, and is very complete. Part III., extending over 70 pages, deals exhaustively with the theory and practice of cable-laying, the whole being amply illustrated. Part IV. explains some of the principal causes of faults in cables, and it is interesting to note that the very latest theory of geological evolution on the sea's bottom (one of the most frequent causes of interruption in cables) has been included by the author under this heading. The fifth and sixth sections constitute the principal and most valuable part of Signor Jona's work. Special attention has been given in considering laws which regulate the manufacture of an electrically perfect cable from the moment the bare wires pass through their first process of insulation until the whole is completed ready for submersion. A full description is given of all the apparatus in use for testing purposes, and the various tables and calculations in reference to the same have been carefully and accurately compiled. Testing for faults, both before and after the cables are laid, completes these sections; this part, however, is obviously only a translation of all the known methods for localising faults, but it is quite up to date and very correct. Parts VII. and VIII. treat of the theory of submarine telephony, as well as telegraphy, and a list of the usual tables and notes, without which no work on telegraphy is complete, brings us to the end of the book.

Although the type is rather small, it is perfectly clear, and there are remarkably few typographical errors considering the number of equations, calculations, and tables, &c. The map at the end shows fairly well all the cables of the world. We strongly recommend Signor Jonas's book to all electrical students who understand the language, whilst to the Italian telegraphist we say: "Ogni impiegato telegrafico, che tiene a cuore la sua professione, dovrebbe acquistarlo studiarlo e tenerlo sempre àdosso."

THE CROMPTON POTENTIOMETER: ITS USE AND CAPABILITIES.—II.*

BY W. C. FISHER, ASSOC.MEM.INST.C.E.

Up to the present the writer has been content to describe, in as diagrammatic and simple a manner as possible, the general outline of the potentiometer system of measurement; all side issues and questions of error and expediency have been avoided, so that those who may not have the time or patience to wade through the whole may, by a cursory glance, as it were, obtain a sufficient grasp of the subject to allow of their understanding and so putting to efficient use the apparatus under their control.

Before proceeding with the details attendant upon the different tests, and a study of the different points of interest, it is perhaps necessary to give a description of the latest type of instrument, and as much as possible the reasons for the adoption of this particular form and the design of its fittings, later on to be followed by the outlines of an ideal instrument.

Fig. 7 shows in plan the instrument as constructed up to date, and which is best described by following the main and galvanometer circuits in conjunction with the diagram of same shown in Fig. 8.

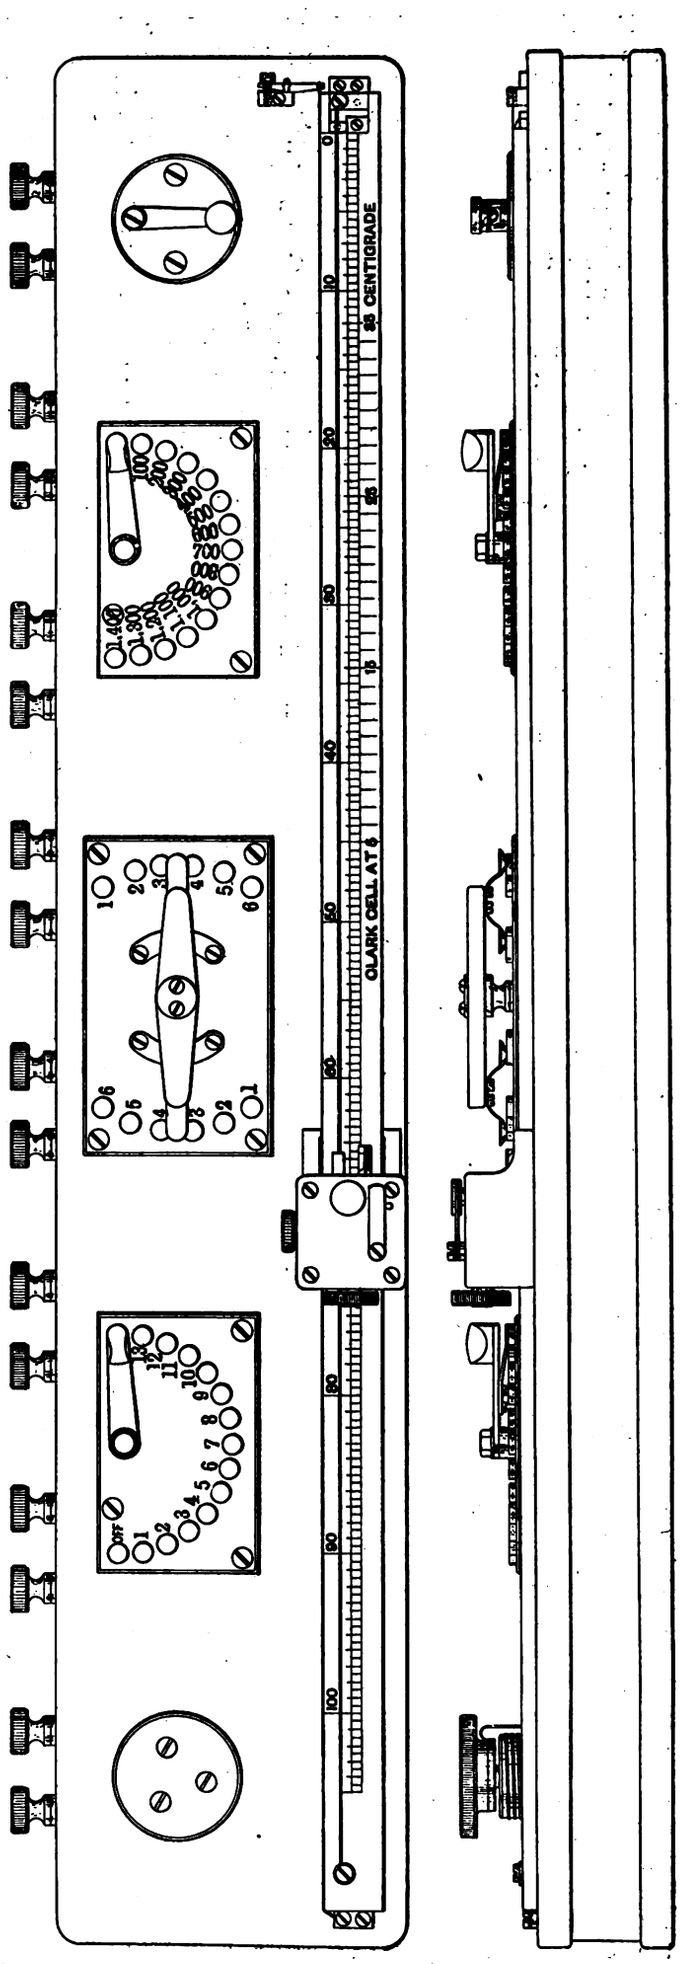

FIG. 7.

Digitized by Google

Commencing with the battery terminals, the left hand or positive is connected direct to the end of the slide wire by means of which we pass along to the 14 sections shown (each equal in resistance to the slide wire and placed inside the instrument), thence by means of a connection to the main rheostat R, thence to the small or fine adjustment rheostat *r*, and so to the negative terminal. (It will be noticed that the connections are so arranged that *all* positive terminals are to the left.) It is easily seen that the E.M.F. at the ends of the potentiometer proper, *i.e.*, the 15 sections, is controlled by the rheostats R, *r*, and may by them be readily adjusted to any value.

The galvanometer circuit from the negative of the right-hand pair of terminals is connected to the galvanometer contact wire (G.W.), which is placed in connection with the desired point of the slide wire by means of the sliding key.

The left-hand or positive terminal of the galvanometer pair is connected to the left-hand segment of the multiple switch (M.S.) through the contact spring upon the lever of which, it passes to either of the contact pins 1, 2, 3, 4, 5 or 6, and thence by a connection to the positive of either pair of the corresponding terminals, which, duly externally connected, returns us by way of the negative terminal and corresponding contacts to the multiple switch, from which, by means of the right-hand segment and connection, we get to the lever of potential switch (P.S.), and thence by either of its contacts to any desired section of the 15 sections, the circuit being completed by way of such sections and portion of the slide wire as may happen to be in circuit. The galvanometer may, if necessary, be short-circuited by means of the key (G.K.) connected to the galvanometer terminals as shown.

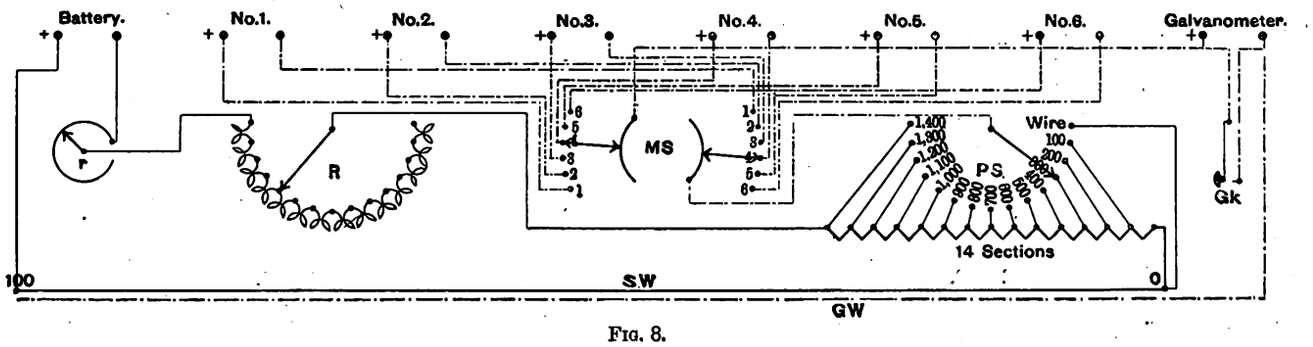

FIG. 8.

The matter of measuring or comparing any unknown value in E.M.F. is made as simple as possible, it being merely attached to either of the pairs of terminals 1, 2, 3, 4, 5 or 6, the multiple switch lever is placed upon the corresponding contacts, and the lever of the potential switch (P.S.) and sliding key (S.K.) moved and depressed until there is no deflection produced in the galvanometer, the position of the lever (P.S.) and key (S.K.) indicating the value direct, a process very much akin to accurate chemical weighing and purely that of potential balance, in which resistance of leads, compensation for temperature, thermo effects, &c., need not for all practical purposes be taken into account.

The calibration of the instrument is equally simple, and is effected and checked in the following manner: The standard is attached to, say, No. 1 pair of terminals, M.S. lever is put on to contact No. 1, the switch lever (P.S.) and sliding key are depressed at the numbers corresponding to the value of the standard, the rheostats R*r* are then adjusted until there is no deflection of the galvanometer upon the depression of the key (S.K.), indicating that the E.M.F. produced by the secondary battery in the main circuit of the instrument is now equal to that of the standard, and the instrument is ready for other comparisons.

With reference to the form and other details of the instrument, all have passed through endless alteration until the present may truly be said to be the survival of the fittest. As at present designed, the instrument is adapted for quick and straightforward working, and may be said to be very compact. Originally the scale was 4 metres long and left much to be desired, inasmuch as the weary tramping to and fro, whilst affording some slight relaxation by constant change in scenery, tended, at the end of a day's hard testing, to the impression that one had been engaged in a walking match of no short distance, to say nothing of the awful labour of calibrating unit length for unit length 4 metres of wire (work which might very well be recommended to the prison authorities as a species of refined hard labour). Certainly when done such a wire became invaluable, and the writer knows of but two in existence. The first deviation from this continuous calibration occurred when the 4 metres were split up into two lengths of 2 metres, then four of 1 metre; in each case one section only undergoing complete calibration, a radical change came about. Abandoning the metre (to the horror of many even to this day) the length of the slide wire was reduced to the prosaic 25in., and the number of its sections increased to 15, in some instances 30 and in one special case 100. It is likely to remain at 25in., for the very simple reason that when that length is divided into 1,000 parts the width of the divisions appear to be the limit that with continued testing and without artificial assistance does not unduly strain the eyes. By the introduction of a lens the scale might be still further shortened, but it is doubtful whether the slight advantage gained in weight and compactness would be worth while.

As shown and described, the scale is straight and divided into 1,000 parts duly numbered upon one side, whilst upon the other side, for convenience and in order to save time, the temperature in degrees Centigrade is engraved opposite the corresponding value of the Clark cell at such temperatures. The question as to whether the scale should be of plain boxwood or celluloid faced is purely a personal one; to some the boxwood is the more pleasing to the eyes, whilst the white celluloid tries them, whether this is due to the glare or to the finer dividing it is difficult to say—probably both have something to do with it. The celluloid has one chief advantage, and that is when dirty it may readily be cleaned with a moist rag without injury, and it certainly wears longest and best.

The straight form of scale has been retained for several reasons. Four years ago the writer designed a circular type of instrument, which was, however, abandoned for several reasons not the least of which was that unless in habitual use the unusual compound crank action of the wrist and elbow, and the figuring at all angles, is irritating and certainly not conducive to quick working, being to anyone but an expert much what a typewriter or A B C telegraph instrument is to a novice; the sweet simplicity and easy working of the straight line movement is entirely lacking, as is also the due alignment of figures, to say nothing of the general mixing up of the hands which it is almost impossible to avoid in the circular form. This opinion has been fully borne out by an instrument recently roughly constructed for trial.

The width of the dividing of the scale has been made as narrow as possible in order to avoid what Lord Kelvin has so aptly termed the pallisading effect.

In order to eliminate all soldered joints as much as possible the 14 sections, each equivalent to the slide wire, are wound in one continuous length, potential points being taken off at fixed distances, having as small a surface contact as is conducive to mechanical strength. The only joint in the whole is at that point where the slide wire joins the remaining sections, and this is made as perfect mechanically and electrically as possible. The sec-

Digitized by Google

tions are of bare wire, wound on a tube the convolutions being as close together as the insulation, mechanical and calibrating reasons will permit; this is done to avoid temperature errors, the whole being as compact as possible. Any alteration in temperature affects the whole equally, so that the possible error from this cause, section for section, is very slight. The insulation employed is paper, and is made as perfect as possible. The whole is aged artificially and literally, being in the majority of cases, under test for quite six months, certainly until no change is perceptible in the value of the sections day by day. Up to a recent date the alloy employed, since the rejection of platinum alloys, has been manganin, but owing to the difficulty in obtaining two samples alike, the alteration of resistance with strain, and from atmospheric causes, it was thought advisable after trial to adopt a nickel-steel alloy. This, up to the present, has given every satisfaction, not the least valuable of its attributes being the fact that it remains untarnished for any length of time, especially if there is the slightest film of oil upon its surface; even in an atmosphere periodically charged with sulphuric acid fumes as emitted from fully-charged accumulators, it has stood for two years without any perceptible oxidation. Its temperature coefficient is, of course, higher than manganin, but on account of the precautions taken above this is negligible for practical work.

As forming no small element in the success and age of an accurate slide wire, it might be here advisable to consider the sliding key (S.K.) at this stage. To those accustomed to the old-fashioned form of metre bridge, and for that matter also the old form of potentiometer, with their brutal type of key, the dinting and denting of the wire and scale indiscriminately by careless hands is often put forward as an argument against the potentiometer. "It is so liable to injury by dents to the wire, either by the key being pressed too hard or something

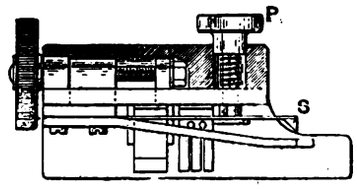

Fig. 9.

falling upon it." The former objection may be put on one side, as the form of key adopted renders it impossible. The design was the outcome of noticing a pupil filled with a more than usual quantity of superabundant energy playing a "tattoo" with both hands upon the key of an old-type instrument. With reference to the second objection, it is not, of course, usual to handle carelessly things approximating in weight to the proverbial "half brick" in a test room. If, moreover, an accident does happen and if in falling the object collides with an instrument, be it galvanometer, slide rule, or Kelvin balance, injury is likely to ensue, in which case one is not likely to condemn the injured, but rather the unfortunate cause of the accident. Besides the slide wire is so easily replaced that the injury to a potentiometer of this description is likely to be far less than to either of the instruments mentioned or those of a similar nature.

The key devised and adopted (Fig. 9) consists of a weak spring, S, having a suitable tip. Normally, if allowed to do so, this spring would make contact with the wire, but it is prevented from doing so by the plunger P with its stronger spring, it is only allowed to come in contact when the plunger is depressed, and then only to the extent of its own weak resiliency. Therefore the energy of the operator is expended upon the plunger spring, and not upon the wire, as in the older form. As seen in the figure, the whole is mounted upon an ebonite carriage for insulation purposes; there are several details shown, such as a micrometer movement, set screw for clamping carriage in fixed position if necessary, and spring for contact with galvanometer wire (G.W.), which runs alongside scale, and is attached to a binding post, as shown, and kept taut by means of an adjustable lever. The lever post is duly connected inside with the galvanometer terminals, as described.

A constant source of annoyance in the earlier form of instrument was the small or fine adjustment rheostat r; all manner of devices and designs were tried without effect in an endeavour to eliminate for ever that irritable source of annoyance, an intermittent or very variable contact. The form shown in Fig. 10 was finally adopted as the most serviceable and nearest to fulfilling the above requirement. It consists of an ebonite turntable T, having a milled edge, and attached to the same by a flange is a screw shank, S S, revolving in a thread cut in the sleeve S, and having a split pin, S P, projecting into a hole bored in the direction of its axis. The sleeve is secured concentrically in an ebonite cylinder, C, having cut upon its exterior a thread of the same pitch as that of the sleeve and screw shank. In this thread is wound a wire, W, suitably secured at each end, and insulated off the metal sleeve. Attached to the flange of the screw shank is a spring, H, which rests upon the wire as shown in figure, making contact therewith. The resistance in circuit is varied by revolving the turntable, together with the spring H, which, riding upon the wire and following it convolution for convolution, puts into circuit more or less of the same. As first designed, after a time, owing to possible wear, the contact between the surfaces of the screw and sleeve became somewhat irregular, and caused trouble; the split pin was therefore introduced as an auxiliary means of contact to take up whatever inequality there might be in that respect between the screw and sleeve, so affording a factor of safety of 3 to 1.

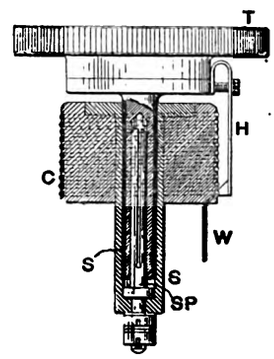

Fig. 10.

The multiple switch shown in the centre of the instrument (Fig. 7) is also the outcome of many devised, and has been definitely adopted as being the best both from a mechanical and insulation point of view. Its mechanical construction is simple, and, as shown, consists of a lever pivoted in its centre and carrying two springs which connect the inner segments with the outer contacts; the lever and standard are solidly built, and form no part of the circuit; the springs are made of just sufficient strength to make effective contact, the whole being therefore of a nature to admit of certain and definite movement, together with ease and smoothness of working—all points of the greatest importance where readings have to be taken in rapid succession. With reference to insulation it will be seen that the design admits of the longest possible paths of surface leakage, the contacts themselves being as far apart as possible, whilst the distance between contacts and segments, or segment and segment, is the maximum possible. In this manner surface leakage is reduced to a minimum at the points where the numerous electromotive forces to be measured are foregathered.

Gas Engine Stations.—The electric railway at Lausanne is operated from a power house in which the dynamos are driven by two gas engines of 130 H.P. each. These engines are by Messrs. Crossley, and use producer gas. The dynamos are belted to the flywheels. The working is said to be very economical, and the best result obtained has been an expenditure of 1·2lb. of anthracite coal per horse-power-hour in ordinary service. The engines are run on an average 18 to 20 hours per day. A careful calculation has shown that the amount of fuel used is 4·5lb. of anthracite per car-mile.

INDUSTRIAL ELECTROLYSIS.

The Hargreaves-Bird process for the preparation of alkali and bleach by electrolysis has lately been cursorily dealt with in these columns, and those points which appeared open to criticism have been duly indicated. On Monday last a further opportunity was afforded of arriving at an opinion of the advantages of the method on the occasion of a meeting of the London Section of the Society of Chemical Industry, when Mr. Hargreaves read a Paper upon the invention in question, and invited criticism from the experts present. We cannot say that this communication added much to what is already public knowledge, for much of the author's attention was directed to the discussion, in a somewhat depreciating sense, of processes professing to accomplish similar ends. Seeing that several of those present were directly or indirectly interested in the processes attacked, somewhat lively rejoinders resulted, and the outcome was rather of dialectical than educational value. It is, however, practicable to compress certain of the contributions to the discussion, and to eliminate the unduly polemical, and thus arrive at the consensus of opinion, not only on the Hargreaves method, but on certain others now prominently before the public. Two of these other processes are dealt with comparatively in our leading article this week, and their relation to the Hargreaves process may be conveniently elaborated here.

It is significant of the need for allaying a vulgar scare which may do harm to a promising industry that Sir Henry Roscoe, with considerable sagacity, confined his remarks to a destructive criticism of the allegations which Mr. Hargreaves had made to the effect that mercury used in the Castner-Kellner process was a potential source of danger to the workmen. In our leading article already referred to, which was written before the present Paper was read, we have already endeavoured to relegate to limbo what is, on the face of it, a fallacy Sir Henry Roscoe added the weight of his testimony to the same excellent end. He stated that the notion that hydrogen was liberated from the surface of the mercury was a mistake, as it was actually evolved from an iron grid placed above the liquid metal. Thus the hypothesis that mercury vapour may accompany the escaping hydrogen goes by the board. Further, he brought forward the results of experience gained during $2\frac{1}{2}$ years' working of the process at Oldbury, which went to show that no mercurial poisoning whatever had occurred among the men employed. A comparison between the Castner-Kellner process and the old mercury method of "silvering" mirrors (in contradistinction to the modern process of depositing silver upon glass to form a reflecting surface) cannot reasonably be made; there is not even an analogy between the two operations. It is particularly necessary, when considering the possible causes o : loss of mercury used industrially, to remember that the metal in its liquid state is most mobile and penetrative, and that small quantities unaccounted for are not necessarily vaporised. The major part of such unrecoverable mercury has escaped through joints and even through bodies (*e.g.*, wood) of apparent solidity. In spite of this tendency, which is well known by all who have to use mercury in the laboratory, the amount lost from 2,782lb. of mercury during eleven weeks of working the Castner-Kellner process was only 7·27lb., or well under 2 per cent. per annum. By taking special care to collect the small quantity of dust and dirt from the floor of the shop as much as 3·3lb. out of the 7·27lb. missing was recovered, reducing the annual loss to something under 1 per cent. We do not think that anyone would hesitate to affirm that the greater part of this residual deficit was due to mechanical loss and not to volatilisation.

For the reason which has been stated above, viz., that Mr. Hargreaves' Paper necessited much controversial discussion, Dr. Hurter's contribution to the matter in hand was mainly taken up with a defence of his own views and statements. He gave an interesting exposition of the relation of working results with modern electro-chemical theory, and pointed out that an electrolytic cell designed for the production of alkali and bleach from common salt must not be considered as one in which the electrolyte is simply sodium chloride, but as a cell containing several substances each capable of acting as an electrolyte—to wit, sodium hydroxide, sodium hypochlorite and sodium chlorate, as well as sodium chloride; further, the distribution of the current in the electrolyte and consequently the amount of electrolysis is directly governed by the relative conductivity of the salts present. By taking advantage of a knowledge of these facts the current efficiency of a given cell can be calculated. It is proper to remark that this is only one factor in the true efficiency of a given cell; the volts must also be taken into account, and, in short, the output must be referred to watts as a standard of comparison.

In Mr. Swinburne's remarks the highly practical statement was made that after all the difference in efficiency of one process from another was not necessarily the largest item in deciding the cost of the processes. Certain fixed, or nearly fixed, charges make themselves apparent in any electrolytic process, and an economy in the electrolytic part of the preparation of commercial alkali and bleach does not necessarily greatly influence the ultimate monetary return of comparable methods. Mr. Blount, arguing on similar lines, spoke of the prevailing trouble of all electrolytic processes—viz, the small output per unit of plant. As not only interest on the capital sunk in the plant has to be paid, but the depreciation of the plant—often a serious item—has to be provided for, a given process, perhaps failing in actual economy of energy, may have the advantage over one in which the capital expenditure or upkeep is heavy. It may further be noted that most of the requirements arising from an adherence to modern dissociation theories are amply covered by older chemical principles, *e.g.*, such as insist on the necessity for the removal of the products for a given reaction from the sphere of the reaction if the continuance of the reaction under the same conditions and with the same expenditure of energy is required. A warning must be issued against the unqualified acceptance of Mr. Hargreaves' figure for the voltage necessary to effect electrolytic decomposition in his cell, inasmuch as the comparatively low value obtained by him—3·4 volts—applies to the production of sodium carbonate and not to caustic soda, the latter substance needing a greater outlay of energy for its formation, and consequently requiring a higher voltage. It is in any case clear that the critical voltage for the decomposition of common salt (about 2 volts) has not yet been approached in any commercial cell.

It will be seen from the foregoing statements that the Paper and the subsequent discussion were useful as leading to the interchange of opinions rather than to the promulgation of ascertained facts. Well-grounded opinions (and some were certainly well-grounded) are fully as useful as facts, and the occasion will not be without fruit, even though some of the processes will suffice to inaugurate an industrial millennium.

ELECTRIC LIGHTING CURVES.

Historians, we understand, find it exceedingly difficult as a rule to obtain an accurate idea of the domestic habits of nations upon whose forms of government or social customs they ponderously discourse. This difficulty ought in the future to be largely mitigated by an intelligent inspection of typical central station load curves. No doubt their peaks and plateaus will be liable to be variously, possibly erroneously, interpreted, but at any rate they should form an excellent basis upon which to build. For instance, armed with a Bankside, a Kensington-court, and a Carnaby-street load curve, a future Froude might easily deduce therefrom that an appreciable portion of the work of the City of London was carried on more or less subterraneously, and that by about eight o'clock the City became for the most part like unto a city of the dead. The Kensington-court curve would tell a true tale as to the average time taken in that quarter to dress for, consume and digest a dinner. A Carnaby-street curve would be an accurate index of the average closing time of West-end shops, and would tell not a little as to the late hours kept in clubs, and the length and number of acts in an average modern drama. Of course, if all other

Digitized by Google

records had been lost, and the above-mentioned curves were the only documents available, the deciphering of them would probably prove about as difficult as that of the first hieroglyphs.

To assist in the elucidation of the accompanying curves of the Cambridge Electric Supply Company, we append a few explanatory remarks. The curves in Fig. 1 were taken from the service mains of several Cambridge Colleges, and give the consumption of electrical energy at these seats of learning during a November

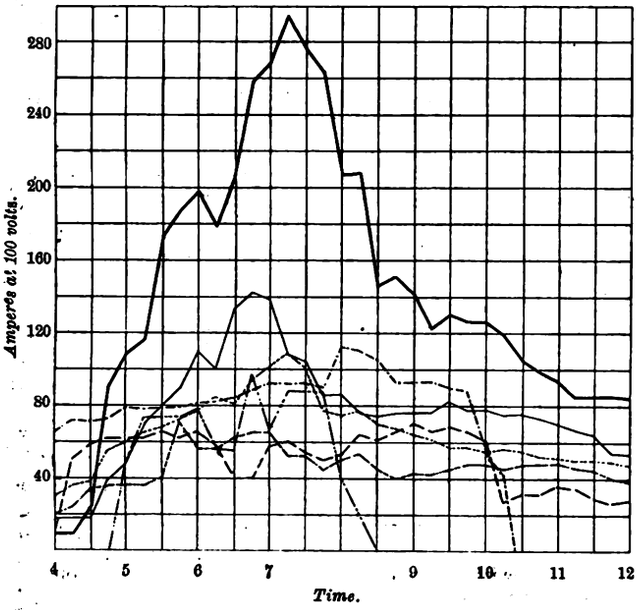

FIG. 1.—College Consumption.

——— Trinity College. ——— Caius College. ——— Union Club.
——·——· Clare College. ——— Newnham College.
------ Sidney College. ——·——· St. John' College.

evening. In the first year of the Company's operations only dining halls and chapels were connected; the curves of these usually overlapped, and for a small total consumption a very large proportion of plant was needed. The authorities are, however, extending the light very largely, and putting it in the men's rooms and in passages and staircases. Caius and Sidney

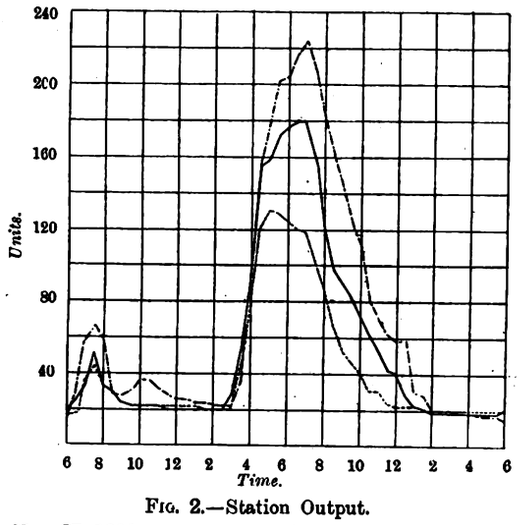

FIG. 2.—Station Output.

——— Nov. 27, 1894. ——·——· Nov. 23, 1895. ------- Dec. 21, 1894.

have it throughout, and Trinity has it in chapel, hall, kitchen, and all men's rooms. St. John's has only chapel and hall lighted, taking no current before 4:45 or after 8:30 p.m. The Union shows the usual regular club load; the peak in this case is owing to the weekly debate, with its pointed remarks. The ladies at Newnham are, as they should be, most regular in their habits; their curve has no chapel spire, and they retire to rest at the commendably early hour of 10:30 p.m.

The regret of the Directors of the Cambridge Company is that the winter term only lasts nine weeks, and that during the darkest months of the year (December and January) the College demand falls lower than in October. In Fig. 2 are shown the all-day curves for the heaviest day in 1894 (November 27th), for December 21, 1894, and for November 23, 1895; the first two showing in a striking manner the contrast between term time and vacation, the last affording an index of the growth of the Company's system since this time last year.

ELECTRIC LIGHTING AND TRACTION NOTICES.

The time for giving official notice in the *London Gazette* of private Bills to be presented to Parliament next Session, and of application to the Board of Trade for Provisional Orders, expired on Saturday last.

From the following list of notices it will be seen that there are 41 electric lighting notices and 37 traction notices. Below are given the figures since 1891 :—

	1891.	1892.	1893.	1894.	1895.
Lighting	34	20	32	32	41
Traction	15	15	17	13	37

Of the 41 lighting notices, 28 are given by local authorities. Only three notices relate to London. Some five notices relate to extensions of areas or amendments of Orders already granted, and one—that of the Burton Corporation—is for power to sell and let out electrical fittings.

The traction notices, even if we make allowance for the extension of time notices, exhibit a great increase over last year's figure, and if only a small proportion of the work foreshadowed is actually accomplished within a reasonable period, the electrical industry will have good cause to congratulate itself.

It is to be observed that four gas concerns are seeking powers to generate and distribute electric energy.

Swansea Corporation	Purchase of tramways. Construction of new tramways. Use of electric and other motive power.
Westlake, W. B.	Construction of tramways (Constitution Hill, Swansea). Use of electric or other motive power.

Gas Companies Seeking Powers to Supply Electric Current.

Bournemouth Gas and Water Company	Powers to generate and sell electricity, and to sell and deal in electrical fittings.
Bexhill Water and Gas Company	Powers to generate and supply electric current.
Guildford Gas Light and Coke Company	Powers to generate and supply electric current.
Ilfracombe Gas Company	Powers to generate and supply electric current

THE COST OF LIGHTING BY GAS AND BY ELECTRICITY.*

1. In accordance with your instructions, I visited Hastings on the 2nd inst. (October) and again on the 11th inst., for the purpose of making comparative measurements of gas lighting and of electric lighting.

2. My attention has been called to a comparative test made by your engineer, and I have seen the arrangements by which this was carried out. A useful comparison could be made in this manner, but I considered it preferable to measure each source of light separately with a bar photometer against a certified standard lamp.

3. On the 2nd inst., I brought with me a portable photometer, and made with it some measurements of the candle-power of various lamps, but as the arrangements for screening reflected and diffused light were not suitable for accurate measurement, I prefer to treat the results as preliminary trials, which enabled me to give your engineer instructions for providing conditions for a second test.

4. On the evening of the 2nd inst. I made several measurements of the illumination in certain gas-lighted shops in Hastings. I have given the results of these measurements to your engineer, but as they do not concern the present comparison, I do not include them in the present Report.

5. On the afternoon of the 11th inst. I inspected the arrangements made according to my instructions for the tests. The lights were arranged in a room at the end of the passage on the second floor of the works. A door had been fitted in the doorway, having an opening, allowing the light to shine down the passage, which was otherwise in darkness. A 10ft. batten was fixed to the wall, and formed part of a photometer bar nearly 200in. in length. On this bar travelled a carriage, on which was mounted a "relief" photometer of my own design and construction, somewhat resembling a "Bunsen," but giving considerably greater sensitiveness. Suitable black screens were provided.

6. The standard was an amyl-acetate or Hefner lamp, having a Reichsanstalt certificate No. 15,346. I take the value of this standard as 0·877 of a standard candle.

7. The instruments for measuring the electric current and pressure were provided by your engineer. For the purposes of the present comparison independent check of their indications was not necessary, as they were themselves, or were compared with, the standard instruments by which the electric supply of Hastings and St. Leonards is measured and controlled. They consisted of a Siemens dynamometer, checked by an Evershed ammeter, and of an Evershed voltmeter. I consider that since alternating currents were used errors of from ½ to 1 per cent. are not unlikely, but I give the results as read or averaged to two or three figures.

8. The measurement of the gas consumption was not so satisfactory, an ordinary 5-light Glover dry meter, No. 737,935, was used. The upper dial registering two cubic feet for one revolution was

* A Report, by Mr. A. P. Trotter, on "Photometric Measurements at Hastings," prepared for the Hastings and St. Leonards Electric Light Company.

Digitized by Google

read, the time for each quarter revolution was taken in minutes and seconds, for purposes of check, and readings by a stopwatch of a number of complete revolutions were used for obtaining the consumptisn. I consider that errors of 5 per cent. are not unlikely, and even 10 per cent. is possible. I have, however, given the results in two or three figures. A pressuie gauge was used.

9. The electrical pressure provided in the test room was rather higher than that of the standard pressure in Hastings and St. Leonards, varying from 102 to 103 volts. This tells in favour of the electric light, but as lamps of rather low efficiency were provided, the results are no better than might easily be obtained from good lamps.

10. The gas pressure was remarkably high, reaching 35 tenths of an inch, but fell considerably towards the end of the tests, which were concluded after midnight. I understand that a high pressure of gas is common in Hastings.

11. The following electric glow lamps were tested:—(*a*) Three Edison-Swan 16 candle lamps for 100 volts, marked B. 16. 100. These had been in use for some weeks in the works. They were measured simultaneously. (*b*) Three "Gabriel" 16 candle lamps for 100 volts, now, measured simultaneously. (*c*) One Edison-Swan "Sunlight" 100 candle-lamp for 100 volts marked 60 F.A. 100. 100.

12. There are three factors in the cost of electric lighting; the price of the supply per unit, the consumption of supply per candle-power, and the cost of lamp renewals. The price of the supply varies in Hastings and St. Leonards on a sliding scale, from 9d. to 4d. per Board of Trade unit, or 1,000 watt-hours. The consumption per candle-power is measured in watts per candle, and I desire to call your attention to the fact that this second factor is of no less importance than the first. The third factor, the cost of renewals, depends on the cost of lamp and on its life. The factor is, as I shall show, generally of minor importance.

13. The results of the tests are as follows:—

Lamp.	Volts.	Amperes.	Watts.	Total candles.	Candles.	Watts per candle.
E. S. 16	103	1·82	187	61	20·3	3·2
E. S. 100	102	2·46	251	—	103	2·43
Gabriel	102	1·7	173·4	52·5	17	3·03

14. The first of these lamps would probably give about 16 candles at 100 volts with 0·63 ampere, thus taking rather less than 4 watts per candle. The only advantage of using lamps taking so much as 4 watts per candle, is a long life, reducing the expense and trouble of lamp renewals. This advantage is dearly bought and is a false economy.

15. Owing to different conditions of radiation, high efficiency can be more easily attained with high candle power lamps, and as the cost of fittings and wiring is reduced by using fewer lamps, such lamps are to be recommended where it is possible to obtain a convenient distribution of light. They are not of course suitable for domestic lighting.

16. On the other hand, great economy of consumption may be realised in domestic lighting by the use of 8-candle or even smaller lamps, since as many, and no more lamps than are needed, may be turned on.

17. Several different kinds of gas burners as commonly used in Hastings and St. Leonards had been provided by your engineer for testing. On the 2nd inst. I made a measurement of a Welsbach burner, but possibly on account of the absence of a suitable governor, or on account of the high pressure of gas, the results were so much lower than those which can be obtained under favourable conditions, that I have rejected them. The mantle-rod of this very fragile burner was unfortunately broken on the 11th inst. at a late hour, and the test could not be repeated.

18. The following gas burners were tested:—(*a*) One "Christiania," with and without opal globe; (*b*) three steatite "union" burners of the Bray type, two being marked 5, and one 6; measured simultaneously; (*c*) one slit batswing.

The last of these burners flared excessively, as is usual in butchers' and other open shops. The pressure was, however, carefully adjusted by a stop-cock, so as just to avoid flaring. The other burners flared a little, but the test was intended to represent the ordinary conditions of use, and was not a scientific investigation. All the burners faced the photometer.

19. The results of the tests were as follows:—

Burner.	Pressure.	Cubic ft. per hour.	Total C.P.	Candles.	C.P. per cubic foot per hour.
Christiania	34½	6·2	...	13·4	2·16
Ditto with globe	„	6·2	...	7·9	1·27
"Bray"	24	34	39	13	1·15
Batswing	3	16	..	38	2·38

20. There are only two factors in the cost of gas lighting—the price of gas per thousand cubic feet, and the consumption in cubic feet per candle, or, as it is commonly expressed, conversely, candles per cubic foot. The cost of burner renewals per thousand candle-hours is too small to enter into the present comparison.

21. It is usual among gas engineers, when they make comparison with the cost of electric light, to neglect all kinds of burners but the "London" argand, which yields about 16 candles for 5 cubic ft. per hour, when carefully nursed with "initial governors," "balance governors," "micrometer regulating cocks," and cabinet work and curtains, in the hands of an expert gas tester. It is only quite recently that the existence of any other kind of burner has been recognised in gas comparisons. I refer to those of the Welsbach light, published by the Incandescent Gas Company, who adopt in one place "an ordinary open flame gas burner," giving "about 15 c.p. with 7 cubic ft. of gas per hour" as a basis of comparison. In another place the comparison is based on "One ordinary (Bray's, &c.) burner, consuming 7ft. of gas per hour, . . . giving a light of about 14 c.p." They publish a Report by Prof. Carlton alluding to "an ordinary good open burner (Bray's Special No. 5) giving 1·83 candles per cubic foot per hour." The general result of a long series of tests of gas burners made under the direction of Prof. Ayrton, F.R.S., and published in *The Electrician*, Vol. XXXII., pp. 94 and 112, was:—1·95 candles per cubic feet for 21 different kinds of burners, at maximum candle-power, and 2·18 candles per cubic foot, under conditions of maximum efficiency. An article comparing the cost of lighting by gas and by electric light, based on these results, appeared on p. 142 of the same volume.

22. I have dealt at some length upon tests for gas burners other than those which I have made for you at Hastings. In order to show that, although the conditions of my tests were not conducive to accuracy, the average result closely approximates to those which I have quoted, I adopt two candles per cubic foot as the basis of the following comparison:—

23. Let a = price per unit of electrical supply in pence.
b = price per 1,000 cubic feet of gas in pence.
c = cost of lamp renewals per 1,000 candle-hours.
d = watts per candle.
e = candles per cubic foot of gas per hour.

Then to find the equivalent price per unit of electrical supply:—

$$a = \frac{\frac{b}{e} - c}{d}$$

To find the equivalent price of gas:—

$$b = [(d \times a) + c]\, e.$$

24. In plainer language, the cost of 1,000 candle-hours in each case is to be compared. For example—let gas be at 3s. 2d. per thousand cubic feet, as at Hastings and St. Leonards, and let the gas burners give two candles per cubic foot. Then 1,000 candle-hours evidently cost 1s. 7d. Again, let the price of electric supply be 6d. per unit, and let the lamps take 3 watts per candle, then 1,000 candle-hours cost 1s. 6d. To this must be added lamp renewals, which I shall show, may be taken at 1½d., making a total of 1s. 7½d.

25. The two following examples of lamp renewals are not extremes:—

C.P. new.	C.P. mean.	Life.	C.P. hours.	Price.	Cost per 1,000 candle-hours.
25	21	1,200	25,200	1s.	0·476
8	6½	800	5,200	1s. 6d.	3·08

26. Returning to the tests of glow lamps, and using the formula already given, I take the electric supply at 6d. per unit, renewals at 1½d., and a gas burner giving 2 candles per cubic foot. The equivalent price of gas in each case is then as follows:—

* Lamp.	C.P.	Watts per C.P.	Equivalent price of Gas.
E. S. 16	20·3	3·2	3s. 5½d.
E. S. 100	103	2·43	2s. 8½d.
Gabriel	17	3·03	3s. 3½d.

27. Using the corresponding formula for the equivalent price of electric supply, and assuming a glow lamp taking three watts per candle, and renewals at 1½d., and gas at 3s. 2d. per 1,000 cubic feet, the equivalent price of electric supply is as follows:—

Burner.	C.P.	C.P. per cubic ft. per hour.	Equivalent price per unit.
Christiania	13·4	2·16	5½d.
Do. with globe...	7·9	1·27	9½d.
"Bray".....	13	1·15	10½d.
Batswing	38	2·38	4⅝d.

* I have taken the actual figures of the photometric tests. The lamps were new, or nearly new. The mean candle-power during their life would be lower.

Digitized by Google

28. It is perhaps somewhat beyond my province here to call your attention to the fact that the comparative cost of lighting by electric light and by gas must be considered on a wider basis than that of light for light. The saving in the cost of re-decoration is very material, and the absence of injury to delicate goods in shops by the products of combustion and vapour of gas, is of no little importance. Besides this, the wholesomeness of electric light for domestic lighting, though it cannot be set down in shillings and pence, is none the less valuable. Especially should this be considered in Hastings, where the very high pressure of the gas doubtless forces much unconsumed gas into the air.

29. I now assume that the price of electric supply varies from 4d. to 8d., and that glow lamps take a mean of 3 watts per candle, and that gas burners yield 2 candles per cubic foot. The equivalent price of gas is as follows:—

Price per unit.	Price per 1,000 cubic feet.
4d.	2s. 4d.
6d.	3s. 4d.
8d.	4s. 4d.

30. Next, I assume that the price of electric supply is kept constant at 6d. per unit, and the efficiency of the lamps is altered. I desire to call your attention to the fact that the effect on the equivalent price of gas is no less marked, and that a knowledge of the efficiency of lamps, which can only be arrived at by careful photometric tests, is as important as a knowledge of the price of electric supply per unit. I have roughly estimated the alteration in life of glow lamps when run at a higher pressure, from the results of various life tests.

Mean watts per C.P.	Renewals of 1,000 c.p. hours.	Price of Gas.
4	1d.	4s. 2d.
3	2d.	3s. 4d.
2½	4d.	3s. 2d.

The old-fashioned 4-watt lamp is not economical, unless the price of electric supply be extremely low; on the other hand, the cost and trouble of lamp renewals eat up the saving in current, if the lamps are overrun too much. Lamps taking 2 watts per candle are offered for sale, but I have no trustworthy information as to their life. The watts per candle rise slightly as the lamp ages.

31. On the 11th inst. I made a number of measurements of the illumination on the pavement between two of the arc lamps on the sea front. The maximum observed illumination on the horizontal plane was found at 18ft. 9in. from the lamp-post, and was equivalent to 0·6 candle at a distance of one foot. The minimum between the lamps was 0·006. The height of the arc above the ground was about 19ft. 8in. Calculating the candle-power from the resulting illumination, I find that the maximum candle-power was at 55½deg. with the vertical. Time did not allow for a sufficient number of measurements, from which the candle-power might be averaged, but the actual single observations give the following results:—

Angle with vertical	35	44½	50	55½	59½	63	66
Candle-power	310	416	475	590	520	500	120

32. Probably nearly as much light is sent upwards, but is nearly all lost. Some of it illuminates the houses facing the sea, and produces an agreeable effect, but the reflected illumination is not appreciable. Lamps giving 500 c.p. in all directions, except at small angles with the vertical, would probably give the same useful illumination.

33. I proceed to compare the cost of lighting of the sea front by arc lamps, with equivalent lighting by "Welsbach" or incandescent gas lamps. But no strict comparison is possible, because the contract for arc lighting includes, I understand, the supply of carbons, trimming, cleaning, all repairs and maintenance of lamps and lanterns and interest on capital outlay. I have no figures before me as to probable cost of lamp lighting and cleaning, damage to mantles by gales and sea water, general repairs and maintenance, nor have I any information as to the possibility of using incandescent gas lights in so exposed a position as that of your arc lamps.

34. According to the price list of the Incandescent Light Company, 60 c.p. can be produced by 3½ cubic ft. per hour. Nothing is said about gradual deterioration of candle power of the mantles, and this too I must neglect. The glass of the lantern will absorb 12 to 14 per cent. (unless cleaned every day), and I doubt if 53 candles would be maintained throughout the life of the "mantles." At this rate 33 cubic ft. of gas would give 500 c.p. At 3s. 2d. per 1,000 cubic ft., 33 cubic ft, would cost 1·254d. I observe that for a consumption of £11 worth of gas, at 3s. per 1,000 cubic ft., the renewals of "mantles" are estimated by the makers at £1. 15s. It may be assumed that for 1·11d. worth of gas the total may be put at 1·43d. for a naked light of 500 c.p. for one hour, exclusive of cost of lamp-lighters, cleaners, damage by wind and water, repairs and interest, on capital outlay.

35. I understand that each arc lamp takes 15 apparent amperes at 50 apparent volts, or 600 true watts, and that for a service of 160,000 lamp-hours per annum, including supply of carbons, trimming, cleaning, repairs to 52 lamps and lanterns, and interest on capital outlay of lamps, post transformers and mains, the sum of £1,300 is paid. This comes to 3½d. per unit, or 1·95d. for a light, reduced and diffused by corrugated glass of a mean of about 500 c.p. for one hour.

36. If incandescent gas lamps were used, a larger number of smaller lights would be employed in order to obtain better distribution, as it would be obviously impracticable to group burners together to give 500 c.p. All the incidental expenses would thus be increased in proportion, although owing to the better distribution of light which would then be possible, some deduction might be affected in the total light.

37. A comparison therefore is impossible without further data, but it is clear that the difference of 0·52 would not cover the incidental expenses, and that, if the two systems of lighting were placed on equal conditions, the cost of gas lighting would largely exceed that of the contract for electric light.

THE ELECTRIC WIRING QUESTION.*

BY FRED. BATHURST, ASSOCIATE.

The author commences his Paper with an outline of the electrical progress of England as compared with that of America. Both countries were, he says, in 1881 on the same basis; the apparatus was crude, experimental and imperfect, and the knowledge in respect to the safe and proper handling of the apparatus employed was limited, and possessed by but few people. In England in 1883 the possible dangers began to attract attention, and rules and regulations were issued which were to control development and progress. In America no regulations were enforced. In 1887 America had in operation (not to mention innumerable isolated plants) some 70 central stations, supplying over a quarter of a million incandescent lamps. In England at this time there was *one* central station, supplying about 5,000 lamps, and a proportionate number of independent plants. On the fire question the author quotes the reports issued by the Underwriters' Electrical Bureau. Taking 1893-1894 as two typical years in which public alarm was prevalent in America, reference to the records shows the occurrence yearly of between 400 and 500 fires traced to electrical causes. Some 320 involve no monetary loss, but the remainder (100 to 200) result in a loss of £300,000 per year. This sum, though apparently large in itself, is less than 1 per cent. of the total fire loss of some £35,000,000 from all causes. The bulk of the electrical loss occurs in the Western States, and for the more populous Eastern towns the proportionate loss is less than one-half per cent. The loss arising from the use of kerosene oil and matches is appalling in comparison, and the figures are best not quoted. Taking the figures from the United States Government records, the average monetary loss per year, for nine years ending 1893, that "lightning" involved amounted to £310,000, or some £10,000 per year more than that caused by the commercial use of electricity. The author, therefore, argues that restrictions of one sort or another have hampered the proper development of the English electrical industry.

The principle obstacle to the general use of electrical applications is that under our present wiring rules it is impossible to place the cost of installation within reach of the great bulk of our people. What is still required is the introduction of rules and regulations which will facilitate the growth of "lower cost wiring." Nothing is further from the author's intention than to advocate cheap, defective, poor, or dangerous wiring. With "lower cost" wiring we could, for instance, successfully compete with the lately introduced "incandescent gas burner," which, priced at about 13s., has had a sale amounting to three-quarters of a million. It is being recognised that the ruling factor which governs public demand is small initial outlay. Even the gas companies are facing the question of fitting consumers' premises free and reimbursing themselves by charging a slightly increased price for the gas supplied.

The five cardinal points of good wiring may be given as safety, durability, convenience, accessibility, and economy. Prof. S. P. Thompson, in a lecture on the subject before the Society of Arts, has embodied the essential features in a few words when he said: "What is wanted is a mode of running wires and fixing switches and other accessories, so that they shall not only be electric tight, but shall also be water-tight, gas-tight, air-tight, oil-tight, fire-tight and even rat-tight." It is the author's belief that all these requirements can be met by the use of *fire-proof insulating tubes.*

* Abstract of a Paper read before the Institution of Electrical Engineers November 28th.

Digitized by Google

It will probably be admitted that wood casing fails in many respects. The idea of its use originated with the telegraphic engineer, and 15 years ago electricians were contented with it. Even on the surface it is neither picturesque nor decorative. It is easy to instal, but its nature prevents any very correct or exact estimate being formed of the labour required. If surface work is required on the score of economy, surely it would be better to adopt "open work" on porcelain insulators—a safe and scientific method of wiring, which can be carried out at a very much lower price. We know this system is discouraged; but it is noteworthy that in the only prominent installation in this country where "open work" has been used, the single source of trouble which occurred arose on a circuit in a damp cellar, where, in order to conform with the fire office "requirements," *wood casing* had been employed. Someone may argue that this could not have occurred if the circuits had been "tested" as the "Rules" recommend. Our "insulation test" never yet told far into the future, and it only tells the present to a limited extent. "Insulation test" cannot discover an unsoldered joint or a dangerous diminution in respect to current-carrying capacity. Every practical man will agree that insulation testing will not necessarily indicate that the wires are at places in dangerous proximity to gas or water systems in the event of moisture appearing.

The recognised shortcoming of wood has brought into use iron and "lead compo" piping. Lead compo pipes afford but little mechanical protection in emergency, and, with respect to "accessibility," have serious drawbacks on account of their flexibility. A large amount of "surface leakage" necessarily arises from the use of any ordinary metal tubing. Moreover, if the insulating material on the conductors has from any reason deteriorated and moisture appears, there will be consequent injury both to conductor and tube. Cases have occurred where the protecting fuses on a circuit did not "blow" before electrolysis promoted a dangerous arc which had burnt a hole in the tube and presented a serious fire risk. If a defect occurs anywhere in the insulation of a wire which is within a metal pipe so that there is electrical contact between the conductor and the pipe, the effect of the fault is virtually transmitted throughout the whole length of piping, there to await or invite trouble elsewhere. With two conductors in the pipe a new and unanticipated electrical condition prevails, because one conductor is now of greater carrying capacity than the other, which has been increased by the capacity of the tube itself. Overheating of the intact conductor can now invite serious trouble at any point. This, the author thinks, explains why overloaded wires in pipes have occasionally "burnt out" at several points at the same instant. It must not be forgotten, also, that failure of insulation on one wire means that the voltage tending to break down the other is doubled, and the actual strain (C^2 R) increased fourfold. Perhaps at this point it will be noticed that these criticisms show, incidentally, how much more the immunity from electrical fires has depended upon the honour and integrity of the contractors than upon the "rules" provided for their guidance. Iron pipes have the disadvantages common to all metal pipes, and, as we know, may rust inside, and this rust is not a condition favourable to "insulation"; they often have burrs or other internal roughnesses which may cause serious mechanical damage to the insulating material as the wires are being drawn in. If iron pipes are screwed at the end for the purpose of jointing, oil is probably employed, and any excessive presence inside is not helpful to a rubber insulation. Cases are on record where this oil has caused extensive mischief. Early in the art of wiring it was recognised that gas brackets, when modified so as to serve as "electrics," should be insulated from the remainder of the gas piping; but now that we are using electric wires themselves in metallic pipes, we appear to overlook the possibility of the electric system being elsewhere in hazardous contact with conjointly-installed steam or water systems. It is now apparent that metal pipes, if not actually harmful, are certainly not particularly helpful to the maintenance of insulation resistance.

It may be thought that we must turn away from tube or pipe methods altogether in order to find economic wiring. Experience in other countries, however, does not show that any "rigid" system of conductors is making progress or headway. No insulated wire has yet been produced which in itself can successfully resist the deteriorating influences present in mortar or plaster. Even lead-covered insulating wires, if directly embedded in plaster, have been found wanting, and give trouble from "earths" and "short-circuits" as soon as moisture has made an appearance. With any rigid method, if walls happen to crack and settle, or plasterers and bricklayers cause damage, a fault may develop which is very difficult to find. Usually, also, they are handicapped commercially in respect to making joints and connections, as these involve risk and trouble even with the highest quality workmen. A cardinal objection to "rigid" methods is the lack of accessibility. All good wiring should be accessible, for with this quality assured half the difficulty of "trouble" is already fought, and any imperfection or injury, whether arising from poor work, negligence, or accident, can be remedied with a minimum of inconvenience. A conduit or race-way is the practical way of rendering wires "accessible," for then the wires installed in them are always open to the inspection of owner or wireman, whenever he wishes to satisfy himself as to their condition or to effect a renewal. "Accessibility" ought, therefore, to be a fire office requirement; with it an inspector can use his *eyes*, and have no need to trust to his *ears* for inspection. From the contractor's point of view "accessibility" is desirable as limiting unfair and injurious competition; for, when an installation can be readily inspected, inferior materials cannot be used for the purpose of cutting down prices, workmanship cannot be scamped, and the "death knell" of unprincipled competition could be sounded for all time.

From a labour-saving point of view a flexible conduit would apparently commend itself. Whilst cases do occur where this is true, every flexible conduit has the inherent drawback, as shown by experience, that the property of "flexibility" may so far assert itself that numberless bends will prevent the wires from being drawn out. Any trouble which then occurs will have to be cut out, or else the circuit must be abandoned or wired anew. Flexible conduits are always at a disadvantage either in respect to moisture-resisting properties, or are wanting in mechanical strength. Bends and elbows must be *rigid*, or it is impossible to draw the wires in or out; and for the generality of work it will be found that a conduit construction permanently rigid throughout is preferable.

More than half of the cost of the wire used is referable to "insulation," and it is "insulation" we strive to keep. It would, therefore, appear obvious that the conduit should be an "insulating" one. An ideal insulating tube should not only be mechanically strong, but also fire-proof and water-proof. With a tube complying with these requirements all possible electrical trouble is minimised, the insulation on the conductors themselves protected from mechanical damage, and is enveloped in a preservative, rather than a destructive, element. Temperature changes are reduced to a minimum, and, if the conduit resists acids, alkalies, and gases, the insulating material on the wire is so shielded that its life is indefinitely prolonged. The author contends, therefore, that an insulating tube method of wiring will prove the ultimate solution of the "electric wiring question."

The author then proceeds to describe the method of wiring originated with Mr. E. H. Johnson. The insulating material employed is a specially prepared hydrocarbon of the bitumen class. The necessary strength in tube form is obtained by using a peculiar grade of fireproof paper material which admits of impregnation. The system provides, the author says, perfect immunity from fire, durability of insulation, accessibility to concealed wires, and reliable service. It has had extensive practical test in America, and more recently in Germany, where its reputation for being the safest, least expensive, and most practical method of wiring is now established. Already in various countries some *two million incandescent lamps* are installed in the three varieties of tube—"plain," "brass-covered," and "iron-armoured."

It has been noted that when deterioration takes place in a plain metal tube, the tube itself becomes a conductor, and invites deterioration at many points. If insulated tubes are used (with two conductors inside), the deterioration on one only brings additional stress upon the other conductor at one point. The tendency in this case is to create a "short-circuit" at the spot affected. In these particular tubes a "short-circuit" presents no danger, as the materials of which they are composed will resist the burning effect of the arc. Many tests have been made, and in every case it has been found that the "arc" increased in length until it broke, and severed the circuit without further danger. Any "short-circuit" trouble, then, removes itself, and its injurious effects are confined entirely within the tube. Since the presence of moisture is the principal cause of "short-circuit," the use of these tubes is likely to minimise the occurrence of trouble, because the tube material is non-conducting in respect to heat, and extraneous changes of temperature fail to produce internal condensation. The use of insulating tubes will also remove the increased danger in respect of wires employed for heating or power applications, which may be temporarily overloaded, and in respect of wires protected by a fuse which through careless replacement has been made too large. It may also be that insulating tube methods of wiring will render it possible to materially modify our present practice in respect to "fusing." There is only one point not yet entirely settled. It is whether the two insulated conductors should be kept together or separated—whether one or two tubes should be employed. Owing to the real necessity with a wood-casing system of keeping the wires apart, some authorities urge that this construction should be applied to tube methods, and that a separate tube should be used for each wire. In alternating-current circuits it is essential to keep the wires close together, to prevent a drop in voltage from inductional effects. Clearly, therefore, in this case both wires should by preference be in the same tube. In England two conductors are already allowed in "compo" pipes. Theory, in the author's opinion, points to the advisability of placing both wires together, and so far, the results of practice favour this view.

Digitized by Google

As far as present experience has gone, it shows that the bituminised tube will, under ordinary conditions, last indefinitely. It can safely be embedded in the lime and sand plaster used in ordinary building construction. The present tendency towards fire-proof building construction, is bringing into use certain cements, caustic enough to attack nearly any material coming into contact with them. The problem thus presented has been successfully solved by the introduction of the "brass-covered" insulating tube. The bituminous material used in these insulating tubes is inert in its nature, and exercises no deleterious influence on the insulating material of the wires themselves. It has sufficient mechanical strength to resist any damage except that inflicted by gross carelessness or design, and in the case of chance mechanical injury to the tube the "accessibility" it provides renders repair easy. In respect of permanence and durability, the advantage of placing the conducting wires in channels which predetermine their relation to any contiguous conducting bodies, is, the author thinks, beyond question. The mischief done to wood casing and "compo" pipe by rats and other vermin is, in the case of these tubes, entirely obviated. From the fact that such inroads are successfully resisted, it would appear that bitumen disagrees with a rat's digestive machinery.

An insulating tube system is also economical. With trained workmen it is estimated that a saving from 25 per cent. to 50 per cent. in the labour of installation is made. Even though the tube in itself is comparatively expensive, if wires suitable to it are employed, the total cost of material will compare favourably with any other system. The insulating properties of these tubes is such as to provide (approximately) an additional "300 megohms per mile" insulation resistance to the wire. We are beginning to appreciate the fact that, although we provide a costly "600-megohm wire," after having installed a few hundred feet our tests indicate a total insulation resistance of only a few thousand ohms. An insulating tube system can assist us to obtain a more commensurable result. If a high insulation test has to be obtained in wiring work, practical experience shows there is little doubt that an insulating tube, and its suitably insulated wire inside, is commercially ahead of a relatively heavily insulated wire. Perhaps the limit of economy will be reached when we know how to "earth" perfectly, and can use a bare copper conductor within a metal-covered insulating tube.

The author concludes by asking the Institution, in considering "the question of electric wiring," in any rules it may issue, to give recognition to, and make due provision for, the use of insulating tubes.

APPENDIX.—*Table Showing the "Insulation Test" required in Various Countries (compiled from Rules of Supply Companies and Fire Offices), voltage of circuits not to exceed 250 volts.*

Size of installation, wired complete.	Country.			
	England (London).	America (New York).	Germany (Cologne).	Austria (Vienna).
Amperes.	Ohms.	Ohms.	Ohms.	Ohms.
10	500,000	2,000,000	100,000	50,000
25	250,000	1,800,000	40,000	20,000

CORRESPONDENCE.

THE PRESIDENCY OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: A Committee, of which we were invited to act as honorary secretaries, was recently formed of the members of the Institution, representative of all sections of the industry, to give effect to the views of a large number of members and associates, on the subject of the forthcoming election of President.

It was considered that in the interests of the Institution, the President should be a man pre-eminent in electrical science or electrical engineering, and that the Presidency should not necessarily be a matter of rotation among the Vice-Presidents.

The balloting list issued by the Council for the year 1896, which is now in the hands of the members and associates, indicates that the Council, in nominating Dr. John Hopkinson for election as President, share the same views. It is believed that in abandoning an undesirable custom, the Council have acted in sympathy with the general wishes of members of all classes; and that the selection of Dr. Hopkinson will meet with the unanimous approval of the Institution.—Yours, &c.,

R. S. ERSKINE,
A. A. C. SWINTON, } *Hon. Secs.*

December 4, 1895.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *November 22, 1895.*

The Niagara Plant.—It is announced that the Niagara Power Company has contracted to extend its wheel pit sufficiently to accommodate ten 5,000 H.P. generating units, and is arranging for the immediate manufacture of three of these units. At the rate at which the Company is now disposing of power it is quite probable that the entire capacity thus provided for will be utilised at no distant date.

Storage Batteries.—The American Institute of Electrical Engineers, at its regular monthly meeting on Wednesday, inaugurated the feature of topical discussion, the storage battery being the subject considered. Communications forming the basis of the discussion were read by Prof. Crocker and by Messrs. Carl Hering, A. E. Childs, N. W. Perry, C. L. Edgar and F. Reckenzaun. Among those who joined in the discussion at the New York meeting, at which the attendance was unusually large, were Messrs. H. W. Leonard, E. T. Birdsall, J. Bentz, J. Appleton, C. Blizard, T. Woolcott, J. W. Lieb, jun., and others. The same evening meetings were also held in Chicago and, for the first time, in San Francisco. Much interest was manifested in this new feature, and it is quite probable that topical discussions will be held hereafter at least once yearly. It can scarcely be said that the storage battery was considered on its merits, as many of those who spoke were commercially interested in its exploitation, while, with one exception, the others seemed to still hold to the idea that, though it may perhaps be allowable at times to speak freely with respect to other electrical subjects, the storage battery must always be handled with the utmost tenderness. Mr. Perry's Paper was the exception referred to, as he not only violently attacked the self-styled "Storage Battery Trust," but contended that the gas engine is in most cases much more efficient than the storage battery as an auxiliary for power houses and central stations. While Mr. Perry very strongly advocated the use of the gas engine generally, he expressed an extremely poor opinion of the sagacity of American gas engine manufacturers and dealers, ascribing to their technical ignorance and business incompetency the fact that the gas engine has received such little employment in this country. Mr. C. L. Edgar, of the Boston Edison station, which has a large storage battery auxiliary, spoke very highly of its use in central stations, the Boston plant having thus far given great satisfaction. Mr. Entz said that the European Tudor Company found it profitable to provide for the depreciation of the central station storage batteries installed by it on the basis of 4 per cent. annually, as the cost thus far of carrying out this guarantee averaged less than 3 per cent. Mr. Hering thought that one of the reasons why storage batteries had not been more successful is that mechanical engineers rather than electro-chemists have presided over its destinies. Mr. J. W. Lieb did not agree with this, but considered that what success had thus far been achieved was through the mechanical engineer and not the electro-chemist.

LEGAL INTELLIGENCE.

Gaskell and another v. Gosling and another.

This case came before the Lord Chief Justice in the Queen's Bench Division on Monday last, and was an action brought by Messrs. Gaskell and Grocott, manufacturers of porcelain parts for electrical apparatus, at Longport, Staffs., against Messrs. Francis and Cunliffe Gosling, trustees to certain debenture-holders in Poole, and White, Limited (in liquidation), formerly trading as electricians at Bread-street, E.C., and Kentish Town, to recover £483 odd, the price of goods alleged to have been sold and delivered between December, 1893, and January, 1895. The defendants denied liability on the ground that the trustees to the debenture-holders had, under their powers, appointed a man named Kelly as receiver, who carried on the Company's business as agent of the Company, and that under such circumstances the Company was liable, and alternatively, if it was held that the winding-up order made in September, 1892, revoked the trustees' powers, then that Kelly was liable personally for the amount claimed. The facts are, shortly, as follows:—Poole and White (Limited) executed at least two trust deeds, the first being in February, 1892, by which all property but uncalled capital was secured for £7,000. On May 18, 1891, a second deed was executed in favour of the Messrs. Goslings as trustees of debenture-holders for £3,000, those gentlemen being members of Messrs. Gosling and Sharpe, bankers, of Fleet-street, London. Those bankers were the holders of the whole of the second issue. To those succeeded a third debenture-holding of £1,000, but that was not material to the present case. On July 22, 1892, Messrs. Goslings appointed Kelly receiver under the deed of May 18, 1892. On July 22, 1892, Kelly took possession as receiver, and carried on the business to January, 1895, and the present claim was in respect to goods delivered by the plaintiffs to the defendants between December, 1893, and January, 1895. Kelly opened a banking account with Gosling and Sharpe, of which firm the defendants were members, and Kelly was required to pay in all moneys received from the business and to draw on that account, his signature being countersigned by that of Mr. John Tryon, a member of the firm of Saltwell, Tryon and Saltwell, of London, defendants' solicitors. This account was opened "Poole and White (Limited), Kelly, Receiver," and it was carried on from July 20, 1892, until September 1, 1892, the date of the winding-up petition, and after that date until January, 1895, in the same fashion.

Mr. HERBERT REED, Q.C., whom with Mr. Hansell represented the plaintiffs, argued that Kelly having by the deed of May 18, 1892, been duly appointed by the defendants, the trustees under the deed of trust of May 18, 1892, and certain debenture-holders, as receiver of Poole and White, Limited, (in liquidation), to carry on the business, was in fact their agent, the defendants being his principals, and as such liable for the goods supplied and delivered to him as receiver by the plaintiffs.

Mr. JELF, Q.C., who appeared with Mr. W. F. Hamilton for the defendants, having addressed the court at some length,

His LORDSHIP decided that the defendants were in fact from December 5, 1893, to January 31, 1895, Kelly's undisclosed principals, and gave judgment for the plaintiffs for the full amount claimed, with costs. In giving judgment his Lordship said that in his view of the case, the question, though in some sense involved in law, was really one of fact—viz., whether, in the circumstances of this case, the plaintiffs were entitled to sue the defendants as undisclosed principals. He read the trust deed of May 18, 1892, under the powers of which Kelly was appointed receiver, and which, he said, was ingeniously framed to clothe Kelly as the agent of the Company. He said he had grave doubts whether Section 24 of the Conveyancing Act would apply to such a case as was contemplated by this deed—viz., the carrying on a concern like this; but from the view he took of the case it was unnecessary for him to decide that point. On July 22, 1892, Kelly, as receiver, takes possession and carries on the business to January, 1895. The present claim is in respect of goods delivered by the plaintiffs to the defendants between December, 1893, and January, 1895, and, therefore, they had only to deal with things as they existed in December, 1893, when the plaintiffs first became creditors to the Company. First, then, what was the position, not as between the defendants and the then going Company, but as between the trustees of the deed of May 18, 1892, and Kelly carrying on this business? He was not prepared to say that the trustees were not the principals even prior to September, 1892, but it was enough for him to consider and determine what was the relationship of the parties and their respective rights during the time when these goods were supplied. After September 2, 1892, he held the position was radically different from the period anterior thereto, because on September 2, 1892, the Company, *qua* Company, had ceased to have any existence as a going concern; and, secondly, the official liquidator took no part in carrying on the Company's business, which was carried on by Kelly. Under the 84th section of the Companies Act date of petition is date of winding-up, and Section 153 says from moment of the order no act or disposition of company whatever is otherwise than null and void. It follows that, if anterior to that there was an agent clothed with the Company's authority, that power had now gone and ceased. But, further, anyone dealing with the Company after that date could have no claim against the Company because the only debts provable are debts due and payable at the commencement of the winding-up. That being so, the liquidator having taken no act or part in business, what is the position? It is going on no longer under the agent of the Company. Months after that, in December, 1893, Kelly had ordered these goods. The plaintiffs were content to take goods without taking Kelly's personal risk, for here Kelly did disclose the fact that he was ordering these goods as receiver, and he therefore clearly incurred no liability as principal. The question was, Who were the real principals carrying on this business? Could it be doubted that they were the defendants in this case?

A stay of execution was granted for a fortnight pending an appeal, and a certificate was given for a special jury.

Kelly's affairs are before the Bankruptcy court, and Mr. F. Mellor watched the case on behalf of the receiver in that matter.

Jeffreys v. the Brush Electrical Engineering Company (Limited.).

This action came before Mr. Justice Hawkins and a common jury on Tuesday last. The plaintiff, Mr. George Jeffreys, 72 years of age, living at Deptford, sued the defendant company to recover damages for personal injuries through the defendants' alleged negligence. The defendants denied liability on the ground that they had not been guilty of negligence.

The plaintiff's case was that on January 8th last, about 7 p.m., he was walking down the City-road, London, when he fell over a small board put about 1½in. above the level of the pavement, at the edge of some works which the defendants were executing in constructing a brick box for electric cables. In consequence of the fall he cut his forehead and injured his eye, and had since been much affected with giddiness.

The defendants called evidence to show that everything that could have been done to protect the public from the excavation had been done, but

The jury returned a verdict for the plaintiff for £50, and judgment was given accordingly.

Cohen v. Electricity Supply Company for Spain.

On page 168 of our last issue particulars were given of an action brought in the City of London Court by Mr. Arthur Cohen, in which it was stated that a verdict was found for the plaintiff and judgment entered accordingly. We regret to say the report, so far as the finding was concerned, was inaccurate, and Messrs. Slaughter and May ask us to state that the jury found for the defendants and not for the plaintiff. It was clearly proved that Mr. Cohen was mistaken in supposing that Mr. Lowrie acted for Mr. Hammond in the matter, Mr. Lowrie having, on the contrary, first approached the Company, and that he was not in the employ of Mr. Hammond at the time. The defendants succeeded on the ground that they bought the transformers in question from Mr. Lowrie direct, without any knowledge that they belonged to the plaintiff. Our report therefore conveys an entirely wrong impression of the result of the action.

Julius Sax and Co. v. Collins.

In the City of London Court the plaintiff company were successful in recovering £12. 5s. for electric current supplied to the defendant at the Central Meat Market, Smithfield. The chief point of interest in the case was that the defendant had disposed of his business to a new tenant, who, he contended, was responsible to the plaintiffs for the sum claimed. The new tenant bore out this statement, but it was admitted that no notice of the change of tenancy was given to the Markets Committee, and that after the alleged change the business was conducted under the style of Collins and Co. The jury, therefore, found for the plaintiffs for the amount claimed.

Sandon and Fowler v. Chelsea Electricity Supply Company.

These are two actions against the Chelsea Company for breach of an injunction granted in respect of vibration caused by the machinery at the Draycott-place station. Counsel moved for a sequestration order, and after some discussion the motions were directed to stand over until this day (Friday) in order that witnesses might be examined in court.

TRADE NOTES AND NOTICES.

TENDERS INVITED.—The Leyton Urban District Council require tenders for electric lighting works, including central station buildings, gas engines, travelling cranes, piping, &c., dynamos, switchboards, &c., storage batteries, and five miles of mains, including laying. Specifications and conditions, &c., can be obtained after Monday next of Prof. H. Robinson, C.E., 13, Victoria-street, Westminster, S.W., and tenders must be sent in to Mr. R. Vincent, Clerk to the Council, Town Hall, Leyton, Essex, before 6 o'clock on Tuesday, 17th inst. Further particulars are given in our advertisement columns.

——— The Corporation of Durban invite tenders for the supply, and for delivery and fixing at Durban, of steam and electrical plant (high-speed steam engines, dynamos, cables, arc and other lamps, accumulators, &c.). Specifications and plans can be obtained from the consulting engineer to the Corporation, Mr. W. H. Radford, Angel-row, Nottingham, and tenders (in duplicate) must be delivered at the offices of Messrs. Webster, Steel and Co. (agents to the Corporation), 5, East India-avenue, London, E.C., by the 28th inst. Further particulars appear in our advertisement columns.

——— The General Direction of the Belgian Posts and Telegraphs invite tenders for the supply of 11,692 telegraph poles. Tenders to the Direction Générale des Postes et Telegraphes, Brussels.

——— The Prussian State Railway telegraph authorities at Saarbrücken invite tenders for the supply of 28 normal sets of Morse telegraph apparatus. Tenders to the Eisenbahn Telegraphen Inspection, Saarbrücken, Germany, by the 16th instant.

——— The Mayor of Charkow (Russia) invites tenders for the supply of steam engines and electrical machinery and apparatus

Digitized by Google

necessary for an electric light installation capable of supplying current to 6,000 incandescents and 500 arcs.

TENDERS INVITED.—The General Consul of the South African Republic invites tenders for the delivery of 5,000kg. 2mm. hard drawn copper wire for the Telegraph Department of the Republic. Conditions, &c., from Messrs. Belinfante Bros., Paveljoensgracht, The Hague, and tenders must be sent in to the Consul, at the American Hotel, Leidsche Plein, Amsterdam, by December 20th.

TENDERS ACCEPTED.—The Middlesex Hospital authorities have accepted the tender of Messrs. Crompton and Co. (Limited) for supplying the generating plant and wiring for the electric light for their convalescent home at Clacton-on-Sea for £3,067. 17s. Mr. Adrian C. Collins is the consulting engineer for the work. The following is the list of tenders received :—

	Generating Plant.	Wiring.
Crompton and Co. *(accepted)*	£2,370 17 0	£697 0 0
Siemens Bros. and Co.	3,153 0 0	850 0 0
Mather and Platt	3,164 15 0	568 0 0
Johnson and Phillips	2,333 19 0	1,246 19 0

———The tender of Messrs. Paterson & Cooper for wiring the Derby Municipal Technical College has been accepted by the Town Council.

TENDERS RECEIVED.—The Vienna Municipal authorities have received 10 schemes for the construction of 50 kilometres of railways, to be worked by electric power in the municipal district of Vienna. Some particulars of the system were given in our issue of August 2nd last. The following is the list of tenders sent in :—

Lachmann, Eduard, Hamburg.;
Springer, Adolf, Vienna ;
Continentale Gesellschaft für Elektrische Unternehmungen, Nuremburg.
Allgemeine Elektricitäts Gesellschaft, Berlin ;
Wiener Bankverein ;
Neue Wiener Tramway Gesellschaft, Anglo-Oesterreichische Bank and Siemens and Halske—Alternatvie projects ;
Bau-Unternehmung Ritschel and Cie (Vienna), and Union Elektricitäts Gesellschaft (Berlin)—Joint projects ;
Stadler, Istvan, Neupest ;
Hampl, Franz, Vienna :
Motoren Tramway Gesellchaft, E. Bierenz, Vienna.

The overhead conductor system will probably be employed in the suburbs, but an underground system of electrical distribution will have to be adopted for the Ringstrasse and adjoining thoroughfares.

SALE BY TENDER.—Messrs. Percy Huddleston and Company announce a sale by tender of the surplus plant at the Woking (Surrey) Electric Light Station. Some particulars are given in our advertisement columns.

PLANT, &C., FOR SALE.—Our advertisement columns contain particulars of modern plant, machinery, &c., for sale, and spacious and well-lighted works, near London, to be let.

DIVIDEND.—A first and final dividend of 2s. 2¾d. in the £ in the bankruptcy of Walter Andreae, lately carrying on business as an electrical engineer under the style of Walter Andreae and Co., is payable at the offices of the Official Receiver, Bankruptcy-buildings, Carey-street, London, W.C., any day (except Saturday) between 11 a.m. and 2 p.m.

APPOINTMENT.—Mr. Charles L. Morgan, assistant engineer of the Great Eastern Railway, has been appointed chief resident engineer of the London, Brighton and South Coast Railway.

VACANT APPOINTMENTS.—As will be seen from our advertisement columns the Vestry of St. Mary, Islington, have vacancies for three electricians (salary £2 per week), one foreman fitter, and a number of workmen in connection with their electricity supply scheme. Written applications have to be sent in addressed to the Electrical Engineer, Electricity Department, 50, Eden-grove, Holloway, London, N., by twelve o'clock noon of Monday, the 16th inst.

———The Devon County Asylum require a fitter to take charge of their electric lighting, heating, and pumping machinery. Applications by the 16th to Mr. Ward, 9, Bedford-circus, Exeter.

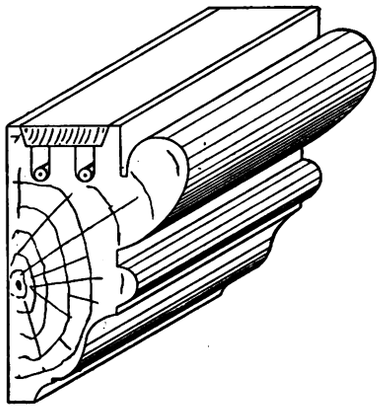
LIQUIDATION.—Mr. Samuel Wheeler, Official Receiver, has been appointed liquidator of the British Steam Generator and Refuse Utilisation Company (Limited). The first meeting of creditors will be held at 33, Carey-street, London, W.C., on Friday, the 13th inst., at 11 o'clock, and the first meeting of creditors will be held at the same place on the same day at 12 o'clock.

BANKRUPTCY.—The first meeting of creditors in the bankruptcy of Walter Raynes Smith, electrical engineer, St. Andries, Hitherfield-road, Streatham, Surrey, takes place at 24, Railway-approach, London Bridge, London, S.E., this day (Friday) at 11:30 a.m. The public examination will take place at the Court House, Wandsworth, S.W., on Thursday next at 12 noon.

HERCULITE AND ELECTRICAL MANUFACTURING COMPANY (LIMITED).—On the petition of the Harburg and Vienna India Rubber Company, Mr. Justice Vaughan Williams on Wednesday last granted a supervision order in the voluntary winding up of this Company.

FINALÉ.—Notice is given that the trustee in the bankruptcy of the Medical Battery Company (Limited), late of 52, Oxford-street, London, W., has been released as from November 21st last.

ELECTRIC WIRE PICTURE ROD.—In our issue of October 4th we gave a description of a form of picture rod adapted for running electric wires, which had been brought to our notice by Messrs.



Skegg and Co., of Salford. To-day we give an illustration of a modified form of the same idea. The rod can, of course, be made of any suitable material, preferably metallic.

BRITISH ELECTRIC TRACTION (PIONEER) COMPANY (LIMITED).—It will be seen from our advertisement columns that this Company is now prepared to develop electric traction enterprise on approved methods according to the requirements of particular localities. Communications must be addressed to Mr. E. Garcke, Managing Director, 1 and 2, Great Winchester-street, E.C.

THE "RADIANT" INCANDESCENT LAMP.—We have received from Messrs. Rose and Bird (Limited), of 120 and 121, Newgate-street, E.C., particulars of the improved incandescent lamps manufactured at the Company's works at Westminster, for which, in addition to low price, it is claimed that a longer life is obtainable for any given efficiency than in any other lamp, that the filaments are of exceptional hardness, strength and uniformity, and that the candle-power and efficiency of the lamps are maintained in a marked degree. The particulars state that these lamps have been made with the utmost care, are accurately tested before being sent out, and that the filament is manufactured by an entirely new process, which, it is claimed, renders the life of the lamp very much longer for the same initial efficiency, resulting in a minimum consumption of current.

THE "ENGINEERING MAGAZINE."—The December number of this Magazine is equal to any of its predecessors, both as regards the variety of the subjects dealt with, and the excellence of its numerous illustrations. The articles in the current issue include "First Principles in Money and Banking," by H. White ; "Side Lights on the South African Gold Boom," by A. Williams, jun. ; "The Distribution of Electric Power at Niagara," by the late F. L. Pope ; "The Education of Mechanical Engineers," by R. H. Thurston, C. E. Emery, and A. E. Outerbridge, jun. ; "Investigation of Public Water Supplies," by F. Davis ; "The Great Modern Transatlantic Steamers," by S. W. Stanton ; "The Cost of Modern Railroad Construction," by J. F. Wallace ; "Schools and School House Architecture," E. C. Gardner ; and "The Manufacture of Steam," by A. S. Writer. The usual exhaustive review of the World's Press is also given. This number, as well as all the back numbers, may be obtained at the offices of the European edition, 1, 2 and 3, Salisbury-court, Fleet-street, London, E.C. A complete index to the main articles in the magazine from the commencement in April, 1891, is now ready, and will be forwarded post free on request.

ASTON.—At a meeting of the Urban District Council the Highways Committee reported that the electrical appliances at the town baths had been examined by Mr. J. C. Vaudrey, of Birmingham, and in consequence of his report notice had been given to Messrs. Fowler, Lancaster and Co. to put in new accumulators in accordance with their contract, failing which the Baths Special Committee have been instructed to obtain tenders for the necessary renewal of the plant and alterations at a cost not exceeding £200.

ASSURANCE OFFICE LIGHTING.—Although the plant for generating electric current at the Prudential Assurance Company's premises in Holborn, London, is still in excellent working order after 10 years' work, the rapid increase of the business has made it necessary to remodel the generating apparatus throughout, substituting plant of a more compact nature. The successful results which have been attained by the use of slow-speed apparatus, has warranted Messrs Drake and Gorham, who have secured the order for the new plant, to keep to this class of plant, but to dispense with all belts and gearing. The engines and dynamos will be built on one shaft, running at 85 revolutions per minute. Marshall

Digitized by Google

engines, of the horizontal type, and Crompton dynamos will be used. There will be over 6,000 lights of 16 c.p. fixed in these offices when the work is completed.

A WARNING.—The Committee of the Cancer Hospital, Fulham-road, S.W., have been the victims of a visit from a man who claimed to be connected with the firm who have the electric lighting of the hospital in hand, and Mr. W. H. Hughes, secretary to the hospital, recommends the custodians of public buildings to be on their guard against the visitor, who has a specious tale to tell and all the appearance of a genuine inquirer. In this case a considerable amount of valuable property was purloined.

AYR.—The Town Hall was lighted electrically for the first time on Tuesday night. Current was also supplied to the greater part of the street lamps. The Artillery Bazaar, which is to be opened on Monday next, is to be lighted electrically.

BELFAST.—At the last week's meeting of the Harbour Commissioners Mr. Davidson asked what was the difference between the working expenses of the electric lighting of Queen's Quay and the old system of lighting by gas, not taking into account the original cost of engines, boilers and dynamos. He had received an answer to that question as follows: Gas for the nine months ending September 30, 1893, £205. 4s. 3d.; electric light for the nine months ending November 30, 1895, £555. 6s. 10d. He wished the Press to know this, for the public to know the difference between electric light and gas. Mr. J. H. Greenhill said he thought it would be unfair that these figures should go to the public without it being understood that the increased facilities for discharging vessels given by the electric light were very great, and that the work could go on night and day. In his view the electric light on the quay—though, as everyone knew, more costly than gas—was really a great economy, having regard to its much greater efficiency. Were they simply to consider the cheapness of a light, they might propose to light the quay with candles. Mr. Andrews understood that the greater cost of the electric light was due to their having a much larger plant than was necessary. Mr. Thompson believed everybody knew that the electric light cost more than gas, but it was adopted because workpeople could do more work in a given time by the electric than by gas light. They must look to the efficiency of a light as well as to its cost.——At the Corporation meeting this week a question was asked as to the condition of the machinery at the Electricity Station, and before this question was answered Mr. Councillor M'Cormick pointed out that in 1892 he and ten other members of the Corporation suggested that an installation for 50,000 lights should be put down, but they were out-voted by 20 members, who favoured a 10,000-light scheme. Events had proved that the minority showed the greater foresight, as 50,000 lights would shortly be needed. Mr. Alderman Pirrie said that no apprehension need be felt as to the supply of current. There were certain matters in connection with the machinery that could be put in perfect order without its being removed from the machinery room. With regard to the extent of their installation there was no doubt that at the commencement they experienced considerable discouragement from the opposition to the electric lighting scheme, but he was gratified to find that all the current they could possibly generate had been applied for, and he hoped that by the time the additional plant was required the new engines would be erected and in working order. The Electrical Committee were preparing a scheme which would be placed before the Council shortly, which would gratify Mr. M'Cormick. In addition, they were taking all possible steps to make the Gas Committee improve the quality of the gas supplied for the public lighting.

BLACKPOOL.—The Borough Electrical Engineer (Mr. J. Hesketh) has been instructed to prepare a scheme for extensions at the electricity supply station.

BRIERLEY HILL (STAFFS.).—At the last meeting of the Council the Lighting Committee recommended that they be empowered to engage an electrical expert at a fee of thirty guineas to advise them on the electric light question, but the matter was adjourned for a month.

BURY ST. EDMUNDS.—Mr. F. H. Medhurst has been appointed consulting engineer to the Town Council in connection with the proposed electric lighting scheme.

CARDIFF.—At the meeting of the Electric Lighting Committee of the Corporation on Tuesday, a letter was read from the Great Western Railway Company asking upon what terms the Corporation would undertake the electric lighting of their new passenger and goods stations. The borough engineer is to report upon the amount of current likely to be required.——The revenue of the electricity department for the quarter ended September 30th last was £671. Since November 1st applications for 943 lamps have been received, which have had to be refused until the necessary extensions to the generating plant have been made. The Committee have instructed the engineer to prepare the necessary plans and specifications and to obtain tenders for the extensions to the plant and works forthwith.——The new wing of the Cardiff Free Library was opened to the public last week. The various reading rooms are lighted electrically. The fittings are of special design, and the lamps hang from wrought iron standards rising from the floor.

CARNARVON.—At the meeting of the Carnarvon Harbour Trust on Tuesday the matter of lighting the harbour electrically was referred to the Surveyor for report.

CHAMBERS OF HANDICRAFT.—The German Federal Council at its sitting at Berlin on Tuesday last approved the Bill for the creation of Chambers of Handicraft.

CHELMSFORD FIRE.—At the meeting of the Chelmsford Town Council last week the Mayor made reference to the recent disastrous fire at Messrs. Crompton's works, and stated that he had received a communication from Mr. Crompton, in which it was intimated that if a public subscription were started for those unfortunately thrown out of employment by the fire, Messrs. Crompton and Co. would head the list with 100 guineas.

CHELTENHAM.—At the monthly meeting of the Town Council on Monday, Mr. Alderman Norman stated that current equivalent to 5,120 c.p. incandescents had been applied for, and would all be connected up within the current week. The electric light undertaking was now in a condition to bear all its expenses. The local gas company has intimated its intention to determinedly oppose the Corporation's proposal to purchase the gas works, and have declined to meet in conference with the Councillors to discuss the matter.

CHURCH LIGHTING.—The electric light has just been introduced into St. Andrew's Presbyterian Church, Nottingham. St. Andrew's Church and the Chapel-street Congregational Church are also lighted electrically.——St. Luke's Church, Newcastle-on-Tyne, is now lighted by electricity. The contract was entrusted to Messrs. Rowland, Barnett and Co.

COVENTRY.—The Board of Trade inspection of the Coventry electric tramways was made on Friday last, and the Company have now received the Board's certificate. The section between the Coventry railway station and Foleshill is now complete, and the cars commenced running on Wednesday last. Satisfactory progress is being made with the Foleshill-Bedworth section.

CROSBY (LANCS.).—At the last meeting of the District Council it was decided to refer the plans submitted by the Liverpool District Lighting Company, who have given notice of their intention to apply for a Provisional Order for the district, to the Surveyor.

DUNDRUM (DUBLIN).—A company has been formed to construct a system of tramways in this district. It has been decided to adopt electricity as the motive power.

EAST GRINSTEAD.—Some time ago Messrs. Owen Lucas and Pike made proposals, on behalf of a company about to be formed, for the introduction of the electric light into East Grinstead. These proposals were referred to the General Purposes Committee, who now recommend the Council not to undertake the supply of electric current themselves, but to give an undertaking to the Company to use electricity for street lighting for 10 years, provided the Company will guarantee to supply current to a certain number of 2,000 c.p. arc lamps for street lighting. The cost per lamp must not exceed the sum now paid by the Council for the gas lamps. This recommendation was agreed to by the Council.

ECCLES.—The Town Council again discussed the electric lighting question at their meeting on Monday last. It was decided to refer the matter to the General Purposes Committee for consideration and report, prior to a special meeting of the Council.

EDINBURGH.—At the meeting of the Town Council on Wednesday the question of extensions to their electric light plant, in view of the probable demand for next winter, was referred to the Electric Lighting Committee for consideration and report.

"EDISWAN" VOLUNTEER FIRE BRIGADE.—The fourth annual dinner of this brigade was held at the Holborn Restaurant on Saturday last under the presidency of Major S. Flood-Page. The company numbered upwards of 100. Mr. H. C. Gover, in giving the toast, "The Edison and Swan Company," said that the Company stood to-day at the head of all electrical manufacturing concerns, and employed thousands of hands. At Ponder's End they had large factories, occupying several acres of ground, and possessing even their own gasworks. They had numerous branches in London and the provinces, and agencies in all parts of the civilised world. It was due to their Chairman to say that he was the guiding genius and moving spirit of the Company. Major Flood-Page, in reply, said that the name of Edison Swan was a household word in all parts of the world, and there were very few places where the Edison-Swan lamp was unknown. There were certain tests going on now with respect to incandescent lamps, but the Edison-Swan Company did not mind who was first to make improvement, but were determined to offer the best goods. Cheapness without quality was no recommendation, and he hoped the public would not be led astray by mere cheapness, but would take into consideration other equally important points. If the Company

Digitized by Google

produced the best article they need not fear German or any other competition, and they were determined to hold their own against all comers. They were selling more lamps to-day than even in the protected period. They all wished prosperity to their useful fire-brigade. He was sure those present sent their heartfelt sympathy and regret to Mr. Crompton at the serious loss sustained by the burning of the Chelmsford works. At Ponder's End they paid especial attention to their fire-brigade arrangements, especially at meal times and closing times, as it was a fact that nearly all fires in factories originated at those times, and it was only by a well organised and efficient fire-brigade service that any large firm could really feel secure. Capt. Dale responded on behalf of the Brigade. After the toast of "The Chairman" had been cordially drunk and Major Flood-Page had responded, Mr. C. M. Downie, the Company's sales superintendent, proposed the toast of "The Press." The company, having inspected a number of new electric fire alarms shown by Mr. Johnson (Mr. Edison's representative in this country), separated, afrer an enjoyable evening.

"ELECTRICAL IMPROVEMENTS."—Under this heading the *Western Mail* of yesterday contains particulars of an influential syndicate formed at Cardiff for the purpose of working two patents, one for making metallic insulators and the other for an improved method of making insulated tubes for electric wiring purposes. The patentees are Messrs. A. J. P. Whitaker and F. G. Treharne, and the first directors of the syndicate are Lord William Beresford, V.C. (Chairman), Mr. Alderman W. H. Matthias, and Messrs. E. Davies, Whitaker and Treharne. Suitable works have, it is stated, been taken on the East Moors, Cardiff, where the erection and fitting of the necessary plant has so far advanced as to enable the syndicate to commence operations by January 1st next.

ELECTRIC FANS.—The electric fans selected for ventilating the Council Chamber at Spring-gardens were made and fixed by the Blackman Ventilating Company.

ELECTRIC LIGHT FOR RAILWAY CARRIAGES.—Amongst many considerable improvements about to be introduced into the trains run by the Great North of Scotland Railway Company is the lighting of the trains by electricity. The only railway system in Scotland on which the carriages are at present lighted electrically is the Glasgow underground railway.

ELECTRIC TRACTION FOR PORTSMOUTH.—At the general meeting of the Provincial Tramways Company held on Friday last at the offices, the Chairman, Mr. George Richardson, having alluded to the working of the Company for the year under review, said that electric traction had now come forward to a very great extent, and they would find if they adopted it that they were not experimenting as they would have been in the first instance. Every country in the world had done a great deal more than England in that direction, and they were handicapped by people who thought that electricity was dangerous, but he did not think there were more people killed by electricity than by other means of locomotion. The board had given notice at Portsmouth that they meant to apply for a Bill to use electricity as a motive power. That was the only place at which they saw any prospect of carrying through a Bill in the ensuing Session, and if that Bill were carried through, there was no doubt it would be of the greatest advantage to the Company. Naturally, they would have to consider the additional capital which would be required; but as there would be no promotion expenses, it would be done at the lowest possible cost. They would, of course, have to provide a sinking fund for the new capital, having regard to the power of the Corporation to take over the line; but he did not think that would be a very onerous task having regard to the great advantages they might expect in changing from horse traction to electricity.

FIRE.—Late on Thursday evening last week a destructive fire broke out on the premises of Messrs. McGaw and Co., timber merchants, makers of wood casings, &c. The Company's premises in York-road, Lambeth, London, are very extensive, and the fire had taken a strong hold before the premises were discovered to be alight.

GLASGOW.—At the meeting of the Police Department of the Glasgow Corporation on Monday last the Watching and Lighting Committee's minutes stated that the Sub-Committee recently appointed to consider the question of the electric lighting of the city, and particularly the kind of arc lamp to be used, had presented their report. The minutes recommended that a small deputation should visit Blackpool for the purpose of examining the street lighting of that town, and this proposal was, after a brief discussion, adopted.

HAMPSTEAD (LONDON).—The Lighting Committee's report recommended that mains and transformers for the supply of electric current be laid down in Frognal-road (from Arkwright-road to Frognal House) at a cost of £258; Fellows-road, £548; Willoughby-road, £143; Dennington-park-road, £128; Fairhazel-gardens (Goldhurst-terrace to Greencroft-gardens), £152; Chislett-road, Priory-road (from Chislett-road to Canfield-gardens), Canfield-gardens (from Priory-road to Fairhazel-gardens), and Fairhazel-gardens (from Canfield-gardens to Greencroft-gardens), £916; and Greencroft-gardens (from Fairhazel-gardens westward to Gleniffer, £128. This recommendation was adopted, as was also the proposal to lay a distributing main in Holly-hill, from Heath-street to the Grove, at a cost of £56. There are now 18,764 8-c.p. lamps connected, and applications for 1,700 more are in hand. The Willesden District Council have postponed the question of lighting the High-road, Kilburn, electrically. The Vestry have instructed their Clerk to write to the London County Council, complaining of the bad quality and quantity of the gas supplied by the gas company to the public lamps in the parish.

HANDSWORTH.—At the meeting of the District Council on Wednesday last, it was decided to oppose any further application of the South Staffordshire Tramways Company for an extension of time for the use of steam power on their system unless the Company could give satisfactory evidence that arrangements for improved means of traction were actually in progress.

HANLEY.—The Town Council have decided to reduce the charge for electric current for motive-power purposes to 3d. per unit net.

HUDDERSFIELD.—A Local Government Board inquiry was held last week at Huddersfield by Mr. G. W. Willcocks, M.I.C.E., into the application of the Corporation for permission to borrow £50,000 for electric lighting purposes. The Town Clerk (Mr. F. C. Lloyd) stated that the Corporation had already obtained power to borrow £50,000 for the erection ot works and the supply of energy for the electric lighting of the compulsory area of the borough, and the generating station was designed to supply current to 20,000 8 c.p. lamps, and their present plant had a capacity for 13,320 8 c.p. lamps. They had 256 customers, and 36 applicants were waiting to be connected. They had thus applications in hand for a total of 22,050 lamps. That exhausted their borrowing powers, with the exception of £3,000, which was required for work in hand, and which would be sufficient to finish the works already sanctioned. The Corporation had had a large demand for the electric light from districts outside the compulsory area, and their electrical engineer estimated that provision should be made in the proposed extension scheme for a total of 50,000 8 c.p. lamps. In 1890 Longwood district was added to the borough, and the Corporation were applying for a Provisional Order for its inclusion in the district of the 1890 Order. There would be a compulsory area for Longwood, so as to comply with the Board of Trade requirements, and this would subsequently be made the subject of a further application for borrowing powers, but was not included in the present application. The Borough Electrical Engineer (Mr. A. B. Mountain) produced and explained the plans of the proposed extensions. The additional capital would be expended as follows: Buildings, machinery, foundations, &c., £11,000; transformer stations, drainage, flooring and sundries, £4,000; two 400 H.P. boilers, £3,000; two 300 unit alternators driven by two 550 H.P. direct-coupled vertical compound condensing engines, £7,000; additions to steam, exhaust, feed, water and condensing pipes, £500: switchboards and regulating apparatus, £1,000; additions to mains inside the compulsory area, £5,000; outside, £16,000; transformers, meters, switches, &c., £4,000. The additional plant would be capable of supplying current to about 36,000 8 c.p. lamps. Alderman Calvert (Chairman of the Electric Lighting Committee) also supported the application, and said that from the many inquiries he had from districts outside the present electric lighting area he felt that if the proposed extensions were carried out a very large increase in the supply would follow. Last year they had a balance of £1,376, after paying working expenses, &c., but owing to the very short period of the loan this sum was not sufficient to pay the interest and the annual proportion which had to be put aside for the repayment of the borrowed money. He, therefore, urged that the period of the loan should be for at least 25 years, and not for 15 years, as in the last case. Alderman J. J. Brook said already there were several applications for current from the Marsh and Lindley districts, and many people would have had their houses wired long ago if current could have been obtained.——Strong opposition is threatened to the proposal made by the Borough Council in its Omnibus Bill for powers to borrow £100,000 for gasworks extension, and an excited meeting of ratepayers and owners of property in the borough was held at the Town Hall on Wednesday to oppose this and other schemes put forward by the Borough Council.

HULL.—At the meeting of the Electric Lighting Committee of the Corporation last week Mr. W. Holder presented a report of the Sub-Committee which attended the Conference at the Board of Trade to amend the regulations governing electrical supply. The report states that the Sub-Committee are deeply concerned in the success of their desire to introduce high voltage lamps which will, they urge, enable the Electric Lighting Committee to greatly increase their income from the supply of electric current without any considerable increase in expense. The report points out that the recommendations of the Sub-Committee were favourably viewed by Sir Courtenay Boyle who accepted amendments to two clauses of great importance which were made by the Town Clerk and Borough Electrical Engineer of Hull. The report concludes

Digitized by Google

by urging that the adoption of a higher voltage will permit of the cheapening of electric supply both for power and lighting purposes, and "presents ideas of economies which will materially cheapen the use of both to the town's benefit." The sub-committee's report was unanimously adopted.

IPSWICH.—The notice given by the County of London and Brush Provincial Company of their intention to apply for a Provisional Electric Lighting Order has been referred to a special committee.

LAMBETH (LONDON).—In our last issue we chronicled the fact that at a special meeting of the Vestry it was decided to appoint a committee of eleven "to consider carefully all the information obtainable on the electric lighting question, and to report thereon to the Vestry." Another special meeting of the Vestry was held on Thursday last, when Mr. Orfeur moved that the above resolution be rescinded. He contended that "there was no necessity for the appointment of a committee, because the Vestry were supplied with all available information three years ago. Moreover, the Vestry was not a trading community, and his view was that if they 'went into' the business of electric lighting, it was only logical that they should 'go into' the business of butchers and bakers." Mr. Orfeur's motion was, after a short debate, carried by 56 votes to 41. No special meeting of the Vestry has, so far, been called to rescind this latest resolution.

LEGAL.—In another column will be found a report of the action "Gaskell and another *v.* Gosling and another," in which a point of the greatest interest to traders was involved. We have several times referred to the peculiar features of the failure of Poole and White (Limited), the appointment of W. J. Kelly as Receiver and Manager for the second debenture-holders, and the subsequent failure of Mr. Kelly. In the light of events connected with the latter failure, it is satisfactory to find that the result of the action has justified Messrs. Gaskell and Grocott, of Longford in taking proceedings to recover their debt of nearly £500. No doubt many other electrical firms will take courage by the result of this action, and proceed to recover their just dues from the debenture-holders in Poole and White (Limited). It was not found necessary in the action under review to call upon Mr. Kelly for evidence, but it would certainly be interesting to thresh out his position in this business. The Lord Chief Justice, in giving his judgment for the plaintiffs, made the remark that "the trust deed of May 18, 1892, under the powers of which Mr. Kelly was appointed Receiver, was ingeniously framed to clothe Kelly as the agent of the Company, and he had grave doubts whether Section 24 of the Conveyancing Act would apply to such a case as was contemplated by this deed." There are several extremely interesting points in this action, and a thorough investigation of all the circumstances of Mr. Kelly's appointment would, we feel sure, prove entertaining. For instance, Mr. Tryon is described in the proceedings as "a member of the firm of Saltwell, Tryon and Saltwell, solicitors, of London, defendants' solicitors"; but our recollection is that Mr. Tryon's name figured very conspicuously for some years in the business of Poole and White, and creditors were uniformly informed by Mr. Kelly, who acted as Secretary to the original firm, that Mr. Tryon's signature was necessary to all cheques passed for payment. Certainly no large credit would have been given to Mr. Kelly himself except upon the understanding that the debenture-holders in Poole and White were his sponsors. It would be satisfactory to learn whether this Mr. Tryon was associated with the original Company of Poole and White (Limited), and, if so, what his interest in that firm really was. There are several more or less recent failures in the electrical trades that call for serious investigation, and, in our opinion, this is especially the case with regard to the failure of Poole and White (Limited) and of W. J. Kelly.

LEITH.—The Leith Dock Commission have decided to extend their electric light installation at the docks. Six arc lamps are to be erected at the Newcastle berth at the back of the Custom House.

LINCOLN.—The Town Council have before them the notice given by the County of London and Brush Provincial Company of their intention to apply for a Provisional Electric Lighting Order for Lincoln.

LIVERPOOL.—For the forthcoming pantomime at the Court Theatre several novelties are to be introduced. These include a large number of electric appliances, the greater part of the work for which has been entrusted to Messrs. G. Ewing Johnstone and Rea, of South John-street, Liverpool. There is to be an elaborate electric curtain, and the preparation of this is entrusted to Messrs. S. H. Heywood and Co., of Manchester. About 1,000 lights are to be put on in the ballroom scene, every person on the stage being made the medium for displaying the electric light in all its glory. There is to be also an electric aerial ballet, "a surprisingly intricate electrical entanglement," and the electric curtain displaying about 700 lights.——It has been decided to light the Princes' Landing Stage by electricity, and the work of erecting four tall posts as a temporary experiment has been completed. If the anticipated success follows the electric light will possibly be placed all over this extensive landing stage.

LLANDUDNO.—The District Council have decided to obtain the opinion of an electrical expert as to the advisability of lighting the town electrically. The Council have received several applications from syndicates for permission to lay a system of tramways in the town and district.——At the meeting of the Llandudno Marine Drive Company last week, the Directors' proposal to sell the undertaking to an electric tramway company for £12,500 was approved.

LLANELLY.—The Town Council have definitely decided to accept the sum of £200 offered by Messrs. J. C. Howell (Limited) for the transfer of their Provisional Order.

LOUGHBOROUGH.—The Borough Surveyor has been instructed to obtain an estimate from the Brush Company for the electric lighting of the Sewage Disposal Works.

MANCHESTER.—At Wednesday's meeting of the Corporation the proposal that application be made to the Board of Trade for a Provisional Order to supply electric current within those areas of the City of Manchester not comprised in the Manchester Electric Lighting Act (1890) was adopted.

MONMOUTH.—The Town Council have received the formal sanction of the Local Government Board for borrowing £20,000 for their combined electric lighting and drainage scheme.

OLDHAM.—At the last sitting of the Electric Lighting Committee a lengthy report from Prof. Kennedy on the pressure at which electric current is at present supplied by the Town Council to its customers was received. The report recommended the Committee to increase the pressure, and to arrange for the introduction new high-voltage incandescents instead of those now in use.

PLYMOUTH.—The local authorities of this town have hitherto been very sluggish in the matter of the introduction of the electric light, but a step in the right direction was taken when it was decided that a deputation from the Corporation should visit Brighton for the purpose of inspecting the famous electricity works in that town. The members of the deputation were wonder-struck at what was shown and explained to them by Mr. Arthur Wright, and it is probable that electric lighting will be considerably advanced in Plymouth by this visit.

PORTSMOUTH.—The Portsea Guardians are considering the question of lighting their workhouse premises electrically.

RIPON.—The City Council are obtaining information with a view to applying to the Board of Trade for powers to supply electric current to the city. Ripon Cathedral is to be lighted electrically by Messrs. G. Harrison and Co., of the Ewer Bank Engine Works.

SHOREDITCH (LONDON, E.).—The Electric Lighting Committee of the Shoreditch Vestry have, it is stated, made arrangements to supply electric current for lighting the stations and tunnels of the new London, Walthamstow and Epping Forest Railway. The Company will, it is estimated, require about 420,000 units per annum. This the Company will take as a purely day load, and will provide the necessary accumulators and subsidiary apparatus to provide current during the hours of heavy load, so that the Vestry will require no extra plant. The Vestry have sealed a contract to supply the Company with a minimum of 300,000 units per annum at 1½d. per unit.

SHREWSBURY.—The formal opening of the Shropshire Electric Light and Power Company's supply station in Eagle Foundry-square is to take place on the 10th inst. An exhibition of up-to-date electrical appliances is to be a feature of the opening.

STAPLETON.—The Electric Lighting Committee have presented a preliminary report on the electric lighting question. The report states that the cost of providing power for lighting such a large district would be prohibitive, especially from one station, and that it would probably be necessary to erect separate generating stations for the Eastville, Stapleton, Ashley Down and Fishponds districts. The Council have decided to oppose the application of the Great Western Electric Light and Power Company for a Provisional Order for the district.

STOCKTON.—Although the Corporation obtained a Provisional Order in 1890, they have taken no steps to comply with its provisions, or to introduce the electric light into the district. In the meantime, several large engineering firms have put down private installations, and as the Gas Committee have discovered that this means decreased consumption of gas, they have just referred the electric lighting question to a sub-committee. The *Northern Echo*, in commenting on this step, says:—

"In Mr. Ford the Corporation have one of the admittedly ablest gas works managers in the country, and he has kept himself abreast with the various new illuminants that have been again and again projected—petroleum, water gas, electricity, &c. We believe that Mr. Ford has never had any doubt that electricity was the coming illuminant, but its application has been so largely experimental as to render him chary in advising the Corporation to adopt it. Its cost is still great, and if we are not mistaken Mr. Ford is still of opinion that almost at any time Edison or some other discoverer may hit upon the invention that will infinitely cheapen it."

Mr. Ford, if correctly described in the above excerpt, is, indeed, progressive. In the meantime isolated installations in the Stockton

Digitized by Google

district are rapidly increasing, which, of course, is proof, if proof were wanted, of Mr. Ford's prescience.

STOKE.—At the meeting of the Town Council held last week the Highways and Lighting Committee reported that they were of opinion that the overhead system of electric traction proposed by the North Staffordshire Tramways Company was the best means of traction which could be adopted at present in the borough, but, before giving formal consent to the introduction of the system, the Town Clerk should be instructed to put himself into communication with the other interested authorities with a view to taking combined action.

ST. PANCRAS (LONDON).—The Vestry have decided to borrow a further sum of £10,000 from the London County Council for electric lighting purposes.

THE COLONIAL OFFICE.—By the instructions of the Colonial Secretary (the Right Hon. Joseph Chamberlain, M.P.) the Colonial Office is to be fitted up for the electric light.

THEFT —At the Central Criminal Court last week, before the Common Serjeant, James Murray (described as a clerk) and George Fowler were indicted for stealing 365 incandescent lamps, valued at £22. 16s. 3d., the property of the General Electric Company. The jury acquitted Fowler, but Murray was sentenced to six months' hard labour.——On Tuesday, at the County of London Sessions, Jacob Glass was acquitted on the charge of stealing a battery and other articles value £25 from the same company.

TORQUAY.—At the last meeting of the Town Council a proposal to consider the advisability of purchasing the Market Company's property in Market-street, with a view to utilising a portion thereof as an electricity generating station, was referred to the Electric Lighting Committee.

TUNBRIDGE WELLS.—The Town Council have received the formal sanction of the Local Government Board to borrow £12,000 for electric lighting extensions.

WATERLOO (NEAR LIVERPOOL).—At the last meeting of the District Council a Committee was appointed for the purpose of opposing the application of the Liverpool District Lighting Company for a Provisional Electric Lighting Order.

WELLS.—At the meeting of the City Council on Monday the Electric Lighting Committee's report recommended that the preparations for the installation of the electric light be proceeded with, and that the Committee be empowered to select a site for the electricity generating station. The report was adopted. Mr. G. W. Wheeler then moved that the whole question of electric lighting be left in abeyance for one week, and that, in the meantime, the Town Clerk be instructed to offer the sum of £14,000 for the Gas Company's works. This was seconded, and, after a long debate, carried by the casting vote of the Mayor.

WHITECHAPEL (LONDON).—On the recommendation of the Streets Committee it was decided, at the last meeting of the Board of Works, to take the necessary steps to oppose the application of the Capital and Counties Electricity Company for a Provisional Order for the district.

YORK.—At the meeting of the City Council on Monday last, the Streets and Buildings Committee's report recommended that Prof. A. B. W. Kennedy be engaged to prepare an electric lighting scheme for the city at a fee of 100 guineas. This reportwas adopted.

NEW COMPANIES, STATUTORY RETURNS ,&c

ELECTROLYTIC RESEARCH SYNDICATE (LIMITED).—This Syndicate was registered on November 25th with a nominal capital of £1,000, in shares of £1 each, to acquire patents, brevets d'invention, licences, or the like, relating to an invention for the production of chrome and other metals by electrolysis or other kindred methods, and alloys of the said metals, in Great Britain or other parts of the world, and to carry on the business of manufacturers of and dealers in all substances, materials, machinery, and things serviceable or useful or used in reference to any of the purposes of the business which the Company is entitled to carry on. The first subscribers, with one share, are: George Bennett, Charles E. M. Crickmore, Alec J. Tod, L. de Fonblanque, Lionel Rogers, Ernest Anderson, and Edward Hayes. The first Directors are to be nominated by the above signatories.

EVANS, O'DONNELL AND CO. (LIMITED).—This Company was registered on December 2nd, with a capital of £45,000, in 60 £7 per Cent. Cumulative Preference and 120 Ordinary shares of £250, to carry into effect an agreement between Arthur G. Evans and John P. O'Donnell, and Eldred W. Stead (for the Company), and to carry on the business of railway signalling engineers and manufacturers. The first Directors are Arthur G. Evans, John P. O'Donnell (Governing Directors), and E. Colman.

MEVAGISSEY ELECTRIC LIGHTING COMPANY (LIMITED).—Registered November 26th, with nominal capital of £1,500, in £1 shares, to carry into effect an agreement with Veale and Co. (Limited) for the establishment of a complete electrical installation in the town of Mevagissey, Cornwall, and to carry on the business of electricians, electrical and mechanical engineers, and manufacturers of and dealers in all apparatus and things required for or capable of being used in connection with the generation, accumulation, distribution, supply and employment of electric light, heat and power. The first subscribers, with one share each, are: Charles W. M. Grier, M.B., Alfred Roberts, David G. Williams, James Kemble, Richard Nicholls, William U. Treleaven, Josiah K. Roberts. The first Directors to be appointed by the signatories.

CITY NOTES.

MEMORANDA —Bank rate, 2 per cent. (Feb. 22, 1894). Price of silver 30⅝d. per oz. (Dec. 5th). Consols (2¾ per cent.) 106½ - 105¾ for money, 106⅝—106¾ for account; 2½ per cent. 103⅞—104⅛ (Dec. 5th). Stock Exchange Settling Days: Consols, Jan. 3rd; Stocks and Shares Continuation Day, Dec. 13th; Ticket Day, Dec. 14th; Pay Day, Dec. 15th. Mining Share Carry-over Day, Dec. 12th.

CITY OF LONDON ELECTRIC LIGHTING COMPANY LIMITED.—For the issue of £100,000 Five per Cent. Debenture Stock (at £128) the prospectus of which appeared in our last issue, applications were received for no less than £522,335. Letters of allotment and regret have been posted.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic returns of this Company for the week ended December 1st were £987, against £928 in the corresponding week of 1894, an increase of £59. The total receipts for the half-year amount to £19,549, against £19,576 for the corresponding period of 1894, a decrease of £27.

COMMERCIAL CABLE COMPANY.—The Directors of this Company have declared a quarterly dividend of 1¾ per cent., payable on January 2nd. The transfer books will be closed from the 20th inst. to January 3rd.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The estimated traffic receipts of this Company for the month of November are £2,414, against £1,738 in the corresponding period of last year.

EASTERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of November, 1895, amounted to £69,461, against £64,095 in the corresponding period of last year.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of November, 1895, amounted to £50,425, and to £43,064 in the corresponding period of last year.

GREAT NORTHERN TELEGRAPH COMPANY (LIMITED).—The traffic returns of this Company for November last were £24,800, and the total receipts for the period from January 1st to November 30th, £286,400, against £248,400 and £261,000 in the corresponding months of 1893 and 1894 respectively.

LIVERPOOL OVERHEAD RAILWAY COMPANY.—The traffic receipts of this railway for the week ended 1st inst. amounted to £1,020. The amount for the corresponding week last year was £902; increase, £118.

REDUCTION OF CAPITAL.—A petition was presented to the Chancery of the County Palatine of Lancaster, on the 27th November, to confirm a resolution reducing the capital of the Manchester Edison-Swan Company (Limited and reduced) from £550,000 to £350,000, and is now pending. The list of creditors of the Company is to be made out as for the 7th January next.

SMELTING COMPANY OF AUSTRALIA (LIMITED).—At the statutory meeting of this Company last week the Chairman (Mr. A. Fowler), after referring to the progress that had been made with the erection of their works in New South Wales, stated that, before the Company purchased the patent rights of the Siemens and Halske electrolytic process, that firm had erected plant in Berlin for the purpose of treating zinc ores, and especially the sulphide ores from Broken Hill, on a commercial scale. This plant was constructed on the same lines as the Smelting Company proposed to follow, it being only necessary to increase the sections of the plant for any required output of zinc. The plant erected at Berlin was not a mere experimental plant; the vats and all the electrolytic appliances were similar to those which they were now purchasing for their works. The process had been thoroughly demonstrated, and the Directors thought they were right in saying that Messrs. Siemens Bros. were the first people who had produced metallic zinc directly from the ore. Mr. Fowler then produced a bar of zinc which, he stated, was produced by Messrs. Siemens and Halske's process from ores from the Broken Hill Proprietary Company's mines. The sample had been carefully assayed by Messrs. Siemens Bros. and Co., chemists, and by Mr. A. Gordon Salamon, the Smelting Company's representative, with the result that it was proved to be practically pure, containing less impurities than the best Silesian zinc, which obtains the highest value in the market. It contained 99½ per cent. of metallic zinc. In the Directors' opinion Messrs. Siemens and Halske's invention was one of the greatest metallurgical inventions of the day. Messrs. Siemens consider that they have finally solved the very difficult problem of producing metallic zinc from the hitherto refractory ores.

STOCK EXCHANGE NOTICES.—Application has been made to the Stock Exchange Committee to allow the further issue of £34,000 Four and a-Half per Cent. First Mortgage Debentures of the Royal Electric Company of Montreal.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).—This Company's traffic receipts for the week ended November 29th, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £2,907.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the fortnight ended November 30th were £2,133, against £2,049,

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

ESTABLISHED 1861.—1878.

No. 917. [Vol. No. 7. XXXVI.] FRIDAY, DECEMBER 13, 1895. PRICE SIXPENCE.

NOTES.

An agreeably falsified prophecy has been made by Prof. A. B. W. Kennedy in regard to the development of the Edinburgh Municipal Electric Lighting undertaking. Prof. Kennedy recommended the City Fathers to lay down a plant capable of coping with 40,000 8 c.p. lamps connected, and led them to anticipate that this lamp connection would be reached in about two or three years, and that the Works Costs (including office expenses) might be expected to amount to 3d. per unit for an annual output of 300,000 units. Although a prophet is usually without honour in his own country, Prof. Kennedy's prophecy was believed in the Scotch metropolis and acted upon, with the pleasing result that after only 7½ months' working some 45,600 8 c.p. lamps are connected to the mains, and the economy of production has been so remarkable that with only 285,000 units sold up to date, the Works Costs (including all office expenses) come out at 1·56 per unit, the greater portion of the period covered being summer time, that season hateful to all true central station engineers. This is, indeed, as Prof. Kennedy states, "quite a record." But, not deterred by previous failures, he still continues to indulge his prophetic vein, and avers that in the first completed year of working the Edinburgh municipal electrical undertaking will have sold over 800,000 units, will have reduced the total working costs to 1½d. per unit, will have earned about £16,000, and last, but not least, will have a credit balance of between £2,000 and £3,000, after paying every charge, including interest and sinking fund. Great credit is certainly due to all concerned, and it will perhaps be divided, as on a well-balanced three-wire system, between Prof. Kennedy, the consumers, and Mr. Monkhouse.

It is needless to say that after this record Prof. Kennedy recommends more plant immediately and 200-volt lamps *in futuro*. Doubling the voltage will, he says, "*quadruple* the present carrying capacity of the mains"; on the assumption, we suppose, of the same *percentage* drop.

It is always a pleasure to contemplate sustained well-organised effort concentrated upon and directed towards a well-defined objective point; and the pleasure is enhanced by contrast with the more common sight of fitful spurts made without any definite notion of what the goal aimed at may be. The spectacle of what has been recently done at Birmingham in the matter of technical education, when contrasted with the vague ideals and frittered funds of many other local authorities, will, we venture to think, give rise to some such pleasurable sensation in the minds of all believers in technical education. In the United States, according to Prof. Thurston, it is impossible to start an institution of the kind with less than £200,000; in Birmingham a capital expenditure of £84,000 has sufficed for the splendidly-equipped school which will be formally inaugurated to-day by the Duke of Devonshire. County Councils here and City Councils there have preferred to grant minute subsidies to all manner of institutions, and have lent a too-ready patronage to the recreative element. In Birmingham art is provided for by the Municipal School of Art; music, languages and recreation—those insidious foes of serious scientific study—by the Midland Institute; but the whole of the money available under the Technical Instruction Act has been devoted to the establishment of a single school in which instruction is to be given in the arts peculiar to the locality and in the fundamental principles of the allied sciences. This is as it should be.

Apparently also the distinction which should exist between a technical college and a technical school—that is to say, between an establishment intended for the training of industrial leaders and an establishment intended for the training of our industrial masses—has been kept well in view at Birmingham. It is generally agreed, at any rate in this country, that technical training is no substitute for the shops, but merely a supplement made necessary by the increasing specialisation of the engineering art. At college the student acquires a firm grasp of scientific principles and a little manual dexterity; in the shops he gains a little more manual dexterity, but above all a knowledge of workshop methods, workshop limitations, and workshop men; in the outside world he rounds off his curriculum with a knowledge of men and manners. Too many, not unnaturally, regard their education as completed after three years at a college and two years in the shop; and late in life, perhaps too late, learn that tact and courtesy—to put it no higher—have their market value. For the apprentice the technical school supplies the systematic manual training now difficult to procure elsewhere, and that insight into scientific principles which, although it may not always lead on to

Digitized by Google

fortune, renders its possessor a happier man and, potentially at any rate, a more useful workman.

THE mention of battery cars has a tendency to make an electrical engineer's mouth water, but hitherto they have done little else than make his eyes weep. The long-looked-for and hardly-striven-for has not yet come, at any rate, in this country; and, what is even more depressing, does not give any very notable promise of coming. Electrical industry has yet to produce a battery commercially adapted to the conditions of traffic on common roads and tramways. The non-existence of such an appliance is, we do not hesitate to affirm, one of the most serious hindrances to electrical progress, possibly the most serious of all; and, conversely, its advent will open up an immense field of electrical applications which cannot now be attempted. Yet, though a really commercial traction battery cannot be said to exist, and though the direction from which it may come is not very clearly defined, we should not care to assert that the outlook is quite hopeless. The storage battery of to-day is less imperfectly adapted to this class of work than the battery of a few years, or even of only one year ago. Structural difficulties and mechanical imperfections are being overcome gradually by the practical manufacturers; while we hope the researches of the many electro-chemists who are engaged in this problem will help things forward on the more scientific side.

AN interesting, and in many respects an instructive, experiment in storage-battery traction for tramcars has recently been undertaken by the New York and Harlem Railway Company, on a portion of their New York tramway system. Some account of this undertaking will be found in our columns this week. The object of the experiment is to obtain "a thorough determination of the feasibility of storage traction"; and however instructive it may be in its initiation, we may safely be sure that it will be even more so in its carrying out and conclusion. Everything that could be done to give the cells a chance has been done. The batteries have been suspended, in easily replacible trays, from the motor trucks, and not within the car bodies, thus enabling these latter to be made as cheaply and as lightly as in ordinary horse or trolley cars. Facilities for changing the batteries on each car have been greatly perfected, an ingenious automatic centring system having been devised for adjusting the position of the car when about to take on a new set of cells; and mechanical appliances are everywhere contrived for transferring the batches of cells between the car sheds and the charging station. Each car carries some 2½ tons of cells, independently of the weight of the trays, &c., and to say nothing of the motors and gear. A storage capacity of 400 ampere-hours, from two batteries, each of 30 "chloride" nine-plate cells in series, has been provided. The decision of the New York and Harlem Railway Company, in the matter of adopting battery traction, will depend upon the results of this experiment; but we think that an interest in it will be felt throughout a far wider circle.

AN unusually appropriate use has been found for a secondary battery on the three-wire system run by the local gas company at Lawrence, Massachusetts. The dynamos are driven by turbines which take water from the Merrimac. Further up stream are a number of water mills, where it is daily the objectionable practice to shut down the sluices and pond back the entire stream for an hour or so. As a consequence the turbines at the electric light station are left high and dry, and to provide for the load at this time a storage battery plant has been laid down. We fancy that in this country a miller would have good ground for action at law if the entire head-water were to be cut off at the sweet will of another miller further up the stream; or, what amounts to nearly the same thing, if one further down stream were to dam the river enough to flood the tail-race of a higher mill. Evidently water rights are not very evenly distributed on the Merrimac.

THE *Electric Railway Gazette* observes that it is a well-known fact that two motormen can take the same equipment over the same route in the same time "and yet use vastly different amounts of power." This suggests a rigorous mathematical method of evaluating a motorman. All that is necessary is to let him run a car, loaded up to standard weight, over a given track in an exact pre-arranged time, making a definite number of intermediate stoppages. An electric meter in the car would give the motorman's figure of merit, which would, of course, be the reciprocal of the number recorded by the meter. This reciprocal should be indicated on his certificate, and his wages might be regulated accordingly. The adoption of this practice would be a new version of "motors, meters and money matters."

Cable Interruptions and Repairs.—There are no cable interruptions or repairs to record this week.

Royal Society.—The following Paper was down for reading yesterday:—Prof. J. C. Bose "On the Determination of the Index of Refraction of Sulphur for the Electric Ray."

Expiry of a Swan Storage Battery Patent.—On the 15th inst. Patent No. 5,494, granted to Mr. J. W. Swan in 1881, will expire. The claim is for "The preparation of lead plates for use in secondary voltaic cells by the combined action of acetic acid, carbonic acid, and atmospheric air, and the subsequent reduction of the carbonate of lead formed to metallic lead. . ."

The Grand-Ducal Technical High School at Darmstadt.—We have received a copy of the finely-illustrated account of the Darmstadt Technical High School which was published on the occasion of the opening of the new buildings on October 28th last. The buildings and the equipment are of the palatial order common to the generality of German institutions of the kind.

Prize Awarded to Dr. Borchers.—The Council of Honour of the German Electro-Chemical Society has awarded a prize of £25 to Dr. Borchers, of Duisburg, in recognition of the services rendered to the Society in connection with the publication of the *Zeitschrift für Elektrochemie*, the *Jahresberichte*, and his book on electro-metallurgy, as well as for his experimental work in electro-chemistry.

The Pacific Cable.—A Melbourne correspondent, under date December 9th, states that the representatives of New South Wales, Victoria, and Queensland, assembled in Sydney, have decided to appoint delegates to the Pacific Cable Conference, probably the Hon. Duncan Gillies and Sir Saul Samuel. New Zealand was not represented at the meeting, but expressed her assent. It is expected that South Australia and Western Australia will acquiesce. The Canadian delegates will almost certainly be Sir Charles Tupper and Mr. Sandford Fleming. It is anticipated that the Conference will meet in London in April next.

Electric Traction on Brooklyn Bridge.—According to the *Electrical World* of New York, three companies, the Westinghouse, General Electric and the Enholme Conduit Trolley Company, made application to have their motors tried on the cars running over Brooklyn Bridge. After some discussion it was decided to allow the Westinghouse and General Electric companies to equip cars with their motors and subject them to a thirty days' test. General Electric motors will have the first trial.

The Electric Light in Hindu Temples.—The *Times of Ceylon* learns that it is in contemplation to introduce the electric light into the Sivan Hindu Temple at Kochicadde, on the main road to Mutwal, Ceylon. The premises of this Hindu place of worship are at present lighted by gas, and the trustees propose to substitute the electric light for gas; but whether they will introduce it into the interior of the building is a matter which is now under their consideration. It is said that, if the Sivan Hindu Temple introduce the innovation, the trustees of equally wealthy temples are sure to follow the example set by their brethren.

Electrical Communication with Lightships.—At a meeting of the Dover Corporation this week the question of the necessity of electrically connecting the whole of the Goodwin lightships with the shore was under discussion. The recent accident to the Ostend mail steamer in the vicinity of the sands was urged as a strong reason for carrying this out. It was proposed that a public meeting should be called for the purpose of passing a resolution impressing the importance of the proposal on the Government, and the arrangements were left in the hands of the Mayor. Similar meetings are to be held in the towns on the East Kent seaboard.

The Classification of Electrical Patents.—Mr. Frederick Walker read a Paper before the Society of Patent Agents at the general meeting of that body on the 11th inst. on "Electrical Nomenclature and the Classification of Electrical Patents." The main object of the Paper was to protest against the classification of the printed specifications at the Patent Office, which, it was urged by the author, are based upon obsolete systems and render what should be a simple search a formidable and harassing undertaking. Mr. Horn, after the discussion, moved "That there should be special divisions of the subject matter indices relating to inventions, and more particularly to electrical inventions, similar to what prevails in the United States and Germany." The Paper and the resolution together form the subject of a memorial to the Board of Trade.

A Flywheel Accident at Albany, N.Y.—The *Electrical Engineer* of New York states that on the 12th ult. a flywheel burst in the power house of the Albany Railway Company. Two houses, one of them two blocks from the power house, were wrecked. Four persons who were in a saloon opposite the power house were injured, one of the pieces of the wheel tearing out the whole front of the saloon, and another piece the whole upper portion of the house. One of the injured men died in the hospital. No one in the power house was hurt. A house two blocks away was wrecked by a flying piece of the wheel 8ft. long and 4ft. wide, which descended in a slanting course, striking the top of the house and tearing out a whole side. A section of the north side of the power house, 25ft. wide, and extending from the ground to the roof, was torn out, and one of the engines and a generator were demolished.

Glow Lamps made in Germany.—The Commission appointed by the Association of German Electric Supply Companies has just published a report on the glow lamp question. A good many tests as to efficiency and life have been made on lamps of various makers, and the result is not very satisfactory. The complaint made by consumers that the lamps have of late been very bad was found to be quite justified. This is mainly put down to the careless sorting, careless marking, low efficiency, and short life of the lamps. Among 70 glow lamps supplied by eight different firms as 16 c.p. lamps with a watt consumption of 3·25 to 3·5 watts per candle, the candle-power ranged from 7·82 to 22·85 candles, and the watt consumption from 2·8 to 6·3 watts per candle. Lamps even of the best makers did not come up to the mark, but the reason for this may be the very low prices which have been brought about by unscrupulous manufacturers who have swamped the market with cheap lamps. The report makes some proposals as to how this state of affairs may be remedied, and as to how lamp manufacturers should be compelled to improve the quality of their lamps.

Water Pipes and Lightning.—M. A. Houdry, in a recent issue of the *Génie Civil*, described a curious case of damage to water pipes, caused by lightning. On October 9th it was found that the water supply of a suburb of Havre was cut off, although the pressure at the distributing point should have been 36 to 44 lbs. per square inch. It was evident that a leak or a stoppage had taken place. Tests showed that it was a leak. The mains were examined, and it was found that a number of lengths of pipe were split. On looking into the matter more closely the pipe was found completely perforated at a spot where the root of a tree was just touching it. Now, on October 9th this very tree had been struck by lightning, and from the point of puncture for a distance of 80 metres almost every length of pipe was split longitudinally. M. Houdry thinks it worth while to call attention to this curious instance, with a view of warning those who are entrusted with the laying of water pipes to keep as far away as possible from trees, not only on account of the damage that may mechanically be done to the pipes by their roots, but on account of the damage that may be done by lightning.

The German Patent Office.—Everyone, says *l'Electricien* in a recent issue, "knows the minute formalities of the Patent Office of the German Empire. The crass Chinese red-tape of the Berlin office is the despair of inventors, and the joy of the patent agent, since the more difficulties there are, the more money flows into his pocket." Applying for a patent, says our contemporary, may only cost 150fr., but its defence may very well cost 1,000fr. But all this is nothing to the case to be mentioned. An electrician applied a few months ago for a German patent. He was informed that the experts entrusted with the examination of patents did not understand his process, did not believe it would work or give the good results he anticipated, and requested him to go to Berlin within two months and show the expert committee the apparatus in working order. The inventor was offered the following alternative. The Patent Office would allow two experts to go to him, and ascertain the actuality of his process—it is needless to say, at the inventor's expense. The electrician in question, not being blessed with too much of this world's wealth, was obliged to decline the visit of the experts from the Berlin Patent Office.

The Rational System of Units.—Referring to recent proposed changes in the system of electromagnetic units, and to the discussion on the Heaviside rational system, the *Electrical World* of New York says:—

"The time would seem to be ripe for the entire subject of rational units and dimensional formulas to be taken up with a view to producing a truly scientific and connected system. This work, of course, is for the savant, and might much better occupy his attention than the creation of further 'practical' units for which there is no need, or, if demanded, might better be left to those who more nearly understand the requirements involved. The fact that such a system would not accord with the units now in use should not deter the work, for it would have its value merely as an exposition of the ideal. In text-books a chapter could be devoted to it, and the student thus taught that the inconsistencies he may find in the accepted systems are not representative of Nature, but come of the limitations of knowledge when the systems were framed, or from the exigencies of practical requirements. Such a chapter would furnish the student's mind with a clearing house for errors, and act as an illustration of the vital necessity for care in the formulation of scientific theory. It is also quite probable that the broad generalisation of scientific ideas which it would represent might direct more attention to higher questions of physical science, as for example, the relation between the various forces of Nature. Nor would it be hopeless to expect that some time such parts of the ideal system as have a practical application will enter into practical use. The teaching of science and the knowledge of scientific methods are becoming more and more general, and we can easily imagine a time when habits of scientific thought will dominate the human mind. Moreover the probable adoption of the metric system by Great Britain will break the spell which has bound the sentiment of her people to illogical systems of units, and, after the first plunge, it may be that she will be the first to welcome, and even advocate further changes, instead of, as would otherwise most probably be the case, rendering futile any hope of international unity.'

Aluminium Solders.—At a recent meeting of the Franklin Institute of America, Mr. J. Richards made some remarks on the above subject. Referring first to the different metallic

Digitized by Google

mixtures which have been proposed for soldering aluminium since M. Christofle's first experiments at Paris in 1855, and pointing out the faults of the various alloys, he proceeds to describe his own investigations into the subject. After experimenting about two years he found that an alloy of zinc and tin in certain proportions, containing a little aluminium and some phosphorus, would meet almost every requirement. The alloy was made by fusing together: Aluminium, 1 part; 10 per cent. phosphor-tin, 1 part; zinc, 8 parts; and tin, 32 parts. It was found, however, that on smelting this solder a more fusible alloy liquated away from it, which also was found to solder better than the original mixture. An analysis showed that its composition was very close to that expressed by the formula Sn_4Zn_3. To obtain this solder Mr. Richards used the ingredients in the proportions of 1, 1, 11, 29, instead of 1, 1, 8, 32, as stated above. The percentage composition of the alloys described may be thus compared :—

—	Original solder.	Found in the liquated alloy.	The formula Sn_4Zn_3 calls for	Solder, as now made, contains
Aluminium	2·36	...	...	2·38 } Zinc + aluminium,
Zinc.....	19·04	...	29·3	26·19 } 28·57 per cent.
Tin	78·34	71·65	70·7	71·19
Phosphorus	0·24	...	...	0·24

The Influence of Electromagnetic Waves on the Electrical Conductivity of Tinfoil Grating.—In connection with the results communicated to the Berlin Physical Society in November, 1894, by Herr E. Aschkinass and the Paper of Prof. Mizuno published on p. 186 of our issue of December 6, 1895, the following experiments of Herr H. Haga (*Wied. Ann.*, No. 11, 1895) will be read with interest. Herr Haga used an apparatus giving long oscillations, as recommended by Ebert. The oscillatory discharges were sent through pieces of copper wire, iron wire and tinfoil, but no change in the resistance was observed, though arrangements had been made for measuring changes of $\frac{1}{20}$th per cent. After these negative results the effect of radiation with different wave lengths was tried, the objects being placed at a distance of less than 50cm. (19½in.) Different tinfoil gratings, 0·05 and 0·01mm. thick, pasted on to ebonite frames, and having resistances of 0·478, 3·155, 11·31 and 36·31 ohms, were employed; also a grating of thin iron wire attached to an ebonite frame which had a resistance of 5·504 ohms, also a german-silver wire of 0·578 ohm, and a tinfoil strip of 1·068 ohms The two last resonated with the primary spark, and secondary sparks could be observed between them and a file. In none of these objects could a trace of a change be observed. When, however, the tinfoil grating strips were only fixed, but not pasted to the ebonite frame, the phenomena observed by Aschkinass and by Mizuno appeared, but the strips had to be placed very close to each other. The changes in the resistances were often very large: the resistance of a grating of 6·7 ohms became, after being exposed to radiation from a primary spark, 3·6 ohms, on tapping it became 5·1 ohms and after another exposure it dropped to 3·2 ohms. This grating was immersed in paraffin, and had then a resistance of 7·85 ohms which was reduced by exposure to radiation to 4·75 ohms, and on tapping the grating it rose to 7·6 ohms. The grating had to be shaken very hard to produce this high resistance. In gratings with larger distances between the strips no change in the resistance was ever observed. For instance, a grating of 22 strips, each ¾mm. wide and ¾mm. from each other, after being exposed to radiation kept its original resistance of 11·85 ohms. After these experiments and those of Mizuno already referred to it is clear that the amount of the change in the conductivity of tinfoil gratings, &c., exposed to electromagnetic radiation depends solely upon the distance of the strips from each other.

Transmission of Electric Power for Dock Pumping.—A plant for the transmission of electric power, that will probably prove to be of interest to engineers concerned in dock-pumping machinery, is being arranged at North Shields, for Smith's Dock Company (Limited), under the superintendence of Mr. A. A. C. Swinton. The Dock Company are engaged in the construction of a floating dock, which will be one of the largest ever built. The pumping out of the dock will be effected by eight 18in. centrifugal pumps, coupled direct to eight 60 B.H.P. electric motors. The pumps, which will be of the type with vertical spindles, are to be placed at the bottom of the dock, and the motors, situated on the top of the dock, above the water line, will be coupled to them direct by means of vertical shafts, the weight of the armatures and spindles being supported by ball thrust bearings. The motors are being supplied by Messrs. Scott and Mountain, and the pumps by Messrs. Gwynne. The necessary switches and resistances for starting and stopping the eight motors will be placed together in a cabin on the upper deck of the dock, being thus under the absolute control of a single attendant. For supplying the necessary current for these motors there will be provided, at a distance of about 200 yards from the dock and connected to it by armoured Fowler-Waring cables, a plant consisting of two 314 B.H.P. Belliss engines, coupled direct to two Crompton dynamos, each developing 425 amperes and 500 volts at a speed of about 250 revolutions per minute. The entire plant is intended to be capable of pumping about 16,000 tons of water per hour through a mean head of a little over 18ft., so that it will be possible to raise the dock loaded with a ship of the largest tonnage it can take in the short space of half an hour. It is believed that this will be the shortest space of time ever attained on such a large scale. Eventually this system may be extended to a second floating dock, and also to an already existing graving dock. At present the pumping in the existing floating dock is effected by pumps placed on the dock worked by steam, which is supplied to them from boilers on the shore by means of flexible steam pipes, an arrangement which is for many reasons uneconomical, troublesome, and therefore unsatisfactory. The electric generating plant under construction will suffice for the working of all the three docks, as they will never be required to be worked simultaneously. It is hoped that by adopting this new system there will be considerable saving of fuel effected. This is probably the first instance in which electricity will be applied to the raising of floating docks.

Contemporary Electrical Science.—It is not often that we can record the discovery of a simple law, and when it does happen it appears surprising that it was not discovered before. Such a law is enunciated in a Paper by Robert Lang in *Wiedemann's Annalen*, No. 11, on the dielectric constants of gases and their chemical properties. The specific inductive capacity K of a gas is determined by its valency. If s is the sum of the valencies of the atoms composing the gaseous molecule or the molecular group, then $(K-1)/s = a$ constant $= 123 \times 10^{-6}$ for all gases at normal temperature and pressure. $K-1$ may be called the electrification number, since it represents that portion of the electrostatic strain which is due to the presence of matter. CO_2, N_2O, and CH_4, having the same valencies, have the same values for K. For CO it is smaller, and for C_2H_4 greater, in the proportions of 3:4 and 3:2 respectively. Hydrogen, being far removed from its critical temperature, occupies a slightly anomalous position. Herr Lang gives a very interesting and suggestive theoretical explanation of the new law.——F. Linde discusses the validity of the Clausius-Mossotti formula for specific inductive capacities in the case of liquefied gases, including CO_2, N_2O, Cl, and of vaseline oil, benzol, and toluol. Plotting the calculated and observed values in curves, the latter are all found to curve the wrong way.——The influence of electric waves upon electric conductivity has been investigated by H. Haga. Tinfoil gratings mounted in ebonite frames had their resistance altered as much as 40 per cent. by electric waves proceeding from an induction coil 50cm. off. But the strips had to be very close together (about 0·1mm.), and they must not be stuck on. The original resistance could be very nearly re-established by concussion.——The circular magnetisation of iron wires traversed by electric currents gives rise to strong "extra currents," from which the magnetic susceptibility may be calculated. This was done by I. Klemencic. He found that in soft iron the circular is smaller than the axial susceptibility. On hardening the wire by drawing, the axial susceptibility decreases more quickly than the other. In Bessemer steel the circular considerably exceeds the axial susceptibility.

MOTIVE POWER AND GEARING.*

BY E. TREMLETT CARTER.

(*Continued from page 147*).

Graded Charge Governors.—Graduation of charge is now almost exclusively effected by controlling the period of gas admission, the entry of air into the cylinder being the same for all loads. The main objection to the reduction of both gas and air is that it gives an attenuated charge which cannot properly be compressed, and which burns uneconomically and with considerable escape of unburnt gas at the exhaust. On the other hand, although the reduction of the gas alone will produce much less fall in initial pressure, because the bulk of the charge is not so greatly reduced, yet the decrease in richness of the gas, especially at very light loads, leads to such augmented after-burning that much of the gas is still unburned by the end of the working stroke. It is advisable, therefore, to limit this method of control to loads which are not small fractions of full load. It must also be observed that with a certain degree of poorness the uncertainty of ignition is much increased. The graded charge governor is commonly used in gas engines for electric lighting purposes, where great steadiness of speed is required. In the early forms of "Otto-Crossley" engine a graded charge governor was used, the gas valve being controlled by a lever which might be actuated by any one of three cams, each of which opened the gas valve for a different length of time. The principle of construction of most modern governors of this class is not essentially different from this arrangement.

Exhaust Governors.—A quite uncommon mode of governing, met with in some small gas engines, is by means of the exhaust governor. In this the escape of the exhaust gases is checked, when it is desired to omit an explosion; the resulting high back pressure in the cylinder causing the gas and air valves to remain closed.

Exhaust Silencers.—An important adjunct to a gas engine is often some means for reducing the noise of the exhaust. The apparatus which is used must not put any great restraint on the escaping gases, otherwise there will be a wasteful back pressure in the engine. The best conditions are met with where several engines exhaust into one common exhaust main, as at the Belfast electric supply station. One of the simplest forms of silencer is a large cone orifice on the end of the exhaust uptake. This has the effect of gently slowing down the gases and passing them into the air with little shock. A modified form is the silencer recommended by Mr. P. Simon. This is very simply made by longitudinally slitting some six or seven feet of the discharge end of the exhaust pipe, and then forcing the slit open to such an extent that the diameter of the slit at the extreme end is about equal to that of the uncut pipe. The slit may be kept in this shape by iron rings and distance plugs placed at intervals. A common form of silencer is constructed of a wrought-iron cylindrical chamber loosely filled with shingle and placed as a cap on the end of the uptake. Occasionally a cylindrical cap without shingle is used.

Starting Apparatus.—Very small gas engines are usually started by hand, simply by giving the flywheel a turn or two until an explosion takes place. With large engines this practice is not only very dangerous, but the amount of effort required makes it inconvenient. Automatic starting devices may be classified under: (1) explosion starters; (2) compressed gas starters; and (3) mechanical starters.

Explosion Starters.—In modern explosion starters gas and air in explosive proportion are admitted into the cylinder, by means of auxiliary valves or cocks, when the piston is at the middle of its forward stroke. An explosion results, the gases being fired either electrically or by the usual ignition tube; and the engine attains high enough speed for the regular valves to be put into action. In some forms, *e.g.* the "Crossley" starter, a number of auxiliary explosions is allowed to take place before the engine goes into regular action. The "Stockport" starter may be taken as representative of this class, and is shown attached to the cylinder in Fig. 79. To use this apparatus the piston must be brought forward to half-stroke, on the usual "impulse" stroke. The ignition tube must be brought to a bright red heat. In this condition all the valves, except the ignition timing valve, will be closed. On the exhaust cam of the engine there are two parts, side by side, the one causing the exhaust to open during every other back stroke (for regular work), and the other opening the exhaust during every back stroke. The roller of the exhaust lever must now be shifted so as to roll on the latter part of the cam. The inlet valve, A, and outlet valve, B, of the starter must next be opened; and the cock, C, connecting the starter with the gas valve box must also be opened. This will cause a mixture of gas and

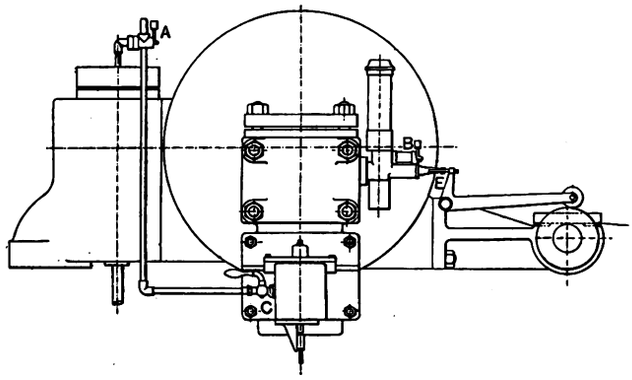

FIG. 79.—"Stockport" Self-Starter.

air to flow slowly through the engine, gradually filling the space behind the piston with an explosive mixture. In a couple of minutes or so an explosion will take place; to be followed by an exhaust stroke; then by another explosion; and so on. When six of these auxiliary explosions have taken place, the extra cocks are closed, the exhaust lever is set to be acted on by the ordinary half of the cam, and the regular valves come into action. Fig. 80 shows an indicator diagram taken during the first and second explosion with the starting apparatus in action.

Compressed Gas Starters.—In early forms of the Otto gas engine the pressure of compressed exhaust gases was used in starting the engine. During the last few strokes, before stopping an engine, the exhaust gases were forced at high pressure into a receiver, where they remained until wanted for

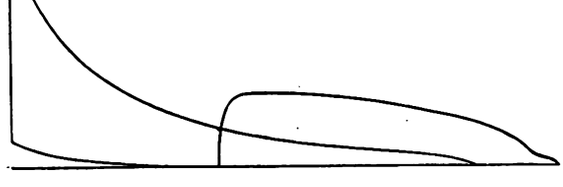

FIG. 80.—Self Starter Diagrams from the "Stockport" Gas Engine.

the next start. Unfortunately, all the gas did not remain; and the leakage was found to be so considerable that the starting impulse could not always be relied on. At a later date it was proposed to make the engine compress an explosive mixture into a receiver; but the danger due to the leakage of such a gas made the plan prohibitive. At the Coatbridge gas engine electric supply station the engines were set in motion by steam derived from the boilers of the gas producer plant. A hand timing valve, by which the regular recurrence of impulses on the engine piston could be controlled, was used.

Mechanical Starters.—In many large gas engine installations the start is made by means of a very small gas engine, which when set in motion is caused to press its flywheel upon the flywheel of the larger engine, and thus to turn the latter

* From a forthcoming work to be published by *The Electrician* Printing and Publishing Company. All rights are reserved.

Digitized by Google

by friction gear. When the larger engine is in full motion the smaller engine is withdrawn and stopped. In electric supply stations where continuous current is used, the engines may be started by running the electric generators temporarily as motors, by means of power derived from the 'bus bars of the switchboard; or, where secondary batteries are available, the current from these may be used to drive the electric motors. This mode of starting is employed at the Belfast electric supply station. The machines are ordinarily shunt-wound, but during the start they are separately excited from the storage cells. The automatic switch is put open at the start, and a gradually lowering resistance is placed in the gap of the open switch. This sends a gradually increasing current to the dynamo running as a motor; and when the engine has given one or two explosions the starting current is cut off, and the engine is run up to speed, the volts being regulated by a resistance in the field circuit, which is still separately excited. When the proper volts have been obtained, the automatic switch may be thrown over to close the circuit and put the dynamo in parallel with the cells. The field coils are then removed from the cell circuit and coupled in simple shunt to the machine.

Cycles other than the Otto.

At a time when every gas engine of importance, and well-nigh every other gas engine, is working on the Otto cycle, it would be inadvisable to devote much space to other cycles. Yet in these there is considerable theoretical interest now, and in the near future there may not improbably be a revival of the practical importance of those types of gas engines which are constructed to work on cycles other than that of Otto.

The Atkinson Cycle.—A genuinely scientific attempt to improve the economy of the gas engine, by modifications of the Otto cycle, was that made by Mr. Atkinson in the cycle which he has employed in his "Differential" and "Cycle" gas engines. It is unnecessary here to describe the details of construction of either of these unfortunately almost obsolete engines. Suffice it to say that both of them were designed to produce a more rapid and extensive expansion of the working substance during the working stroke, as compared with the period and extent of the other strokes. The cycle was as follows: (1) During the first stroke gas and air were drawn into the cylinder, the stroke being comparatively short; (2) during the next, or first return stroke, these gases were compressed, this stroke being somewhat shorter than the first one; the ignition now took place, and then (3) the working stroke of some two or three times the length of the charging stroke ensued; and finally, completing the cycle, (4) the exhaust stroke drove the products of combustion almost completely from the cylinder. For example, in one of the "Cycle" engines the length of the four strokes were respectively 6·3in., 5·03in., 11·3in., and 12·43in. The effect of this considerably augmented expansion of the hot gases is seen in the following comparison between the distribution of heat in an "Otto" and in an "Atkinson" engine. The data are taken from the published results of the Society of Arts trials of gas engines in 1888-9.

Distribution of heat.	"Otto" cycle. Per cent.	"Atkinson" cycle. Per cent.
Heat utilised in indicated work.....	21·2	22·8
Heat absorbed by jacket.....	43·2	27·0
Heat otherwise wasted	35·6	50·2
	100·0	100·0

This Table forcibly brings out the fact that an attempt to recover heat from the water jacket is apt to result in augmented exhaust waste. Mr. Atkinson has succeeded in preventing 37·5 per cent. of the Otto-jacket heat from going into the jacket; but, of this heat thus saved, he has made a present of 90 per cent. to the exhaust and only 10 per cent. to the useful work. Nevertheless, the improvement is a decided one, and it is based upon a sound principle that will doubtless, in time, be further developed.

The Griffin Cycle.—A six-stroke cycle was adopted in the "Griffin" engine, made by Messrs. Dick, Kerr and Co. The main feature of this cycle was the interception of two complete strokes between the exhaust and the charging stroke of the ordinary Otto cycle. Otherwise the six-stroke cycle was not different from that of Otto. The purpose of this entire idle revolution was to draw a charge of fresh air into the cylinder, and to reject along with it the residual products of combustion. This is known as a *scavenging charge*. Its effect is twofold; firstly, to cleanse the inside of the cylinder, thus enabling a richer explosive charge to act on the piston; and secondly, to cool the cylinder walls. Working on this cycle, the gas engine is found to run very cool and to be capable of making unusually long runs. The defect of the cycle, when it is applied to only one end of the cylinder, is the great interval between the impulses, there being only one explosion during every three revolutions at full load. This defect is usually remedied in the "Griffin" engines, by making those engines double acting. In this case the following represents the distribution of the two cycles:—

Stroke.	Crank end.	Back end.
First forward (*i.e.*, *towards crank*).	Compression of gas and air.	Drawing in air.
First backward.	Ignition and expansion of explosive charge.	Driving out air and residual waste gas.
Second forward.	Exhaust.	Drawing in gas and air.
Second backward.	Drawing in air.	Compression of gas and air.
Third forward.	Driving out air and residual waste gas.	Ignition and expansion of explosive charge.
Third backward.	Drawing in gas and air.	Exhaust.

"Motor and Pump" Cycles.—A numerous class of gas engines has been constructed to work upon what may be styled the "motor and pump" type of cycle. In these engines the gas and air are drawn into a cylinder separate from the motor cylinder, and are usually there compressed, before being passed into the motor cylinder for explosion and ultimate exhaust. The direct advantage of this arrangement is that an explosion can be effected once during every revolution, since the first half of the Otto cycle can be made simultaneous (in the pump) with the second half (in the motor). The first practical example of this class was the Clerk gas engine, with the slight modification that the compression took place in the motor cylinder. In the Clerk engine gas and air were first drawn into the pump cylinder; but during a later part of the stroke of the pump piston, only air. On the opening of the communication between the two cylinders, the contents of the pump cylinder were forced into the motor cylinder, driving from out the latter the products of combustion which had remained in it. It was supposed that the various gases would be so stratified that the explosive charge would drive out the waste gas without the escape of any gaseous fuel into the exhaust pipe; but in reality a good deal of gas was thus lost. The return stroke of the motor piston was completed during the compression of the explosive charge in the motor cylinder (the exhaust having been closed at half-return-stroke); and during the next forward stroke the ignition and expansion of the charge occurred. In the more modern engines worked on the "motor and pump" cycle, such as the early "Stockport" engines, the charge is fully compressed in the pump and is delivered in a compressed state to the motor cylinder just before ignition.

Rotatory Gas Engines.—The existence of a cycle in a gas engine is the cause of two of its chief defects: (1) the great variation of temperature of the different parts of the cylinder; and (2) the enormous variation in the useful effort exerted by the engine. Both of these defects would be removed if a gas engine could be made rotatory in its action, as in a water or steam turbine. What is required is that the expansive force of the igniting gas should act continuously—or at most by a quick succession of impulses—upon rotating vanes or curved surfaces. Passing from one series of vanes to another, the gas would gradually impart its energy to the rotating parts; but each particular

Digitized by Google

vane would be at a constant, or nearly constant temperature, and would exert as nearly constant an effort. The only drawback at the present time is the practical impossibility of finding a material suitable for such vanes; but the problem might be simplified if we were to be content to have a large clearance space between the vanes and their chamber, for then they might be made of some refractory material such as is used for furnaces at very high temperature. In fine, it will not be until we work the gases in a gas engine at furnace temperatures, and permit of the engine itself becoming a furnace, that we can realise the best part of the available energy in an explosive charge of gas and air, or oxygen.

(To be continued.)

CROMPTON-D'ARSONVAL GALVANOMETER.

A d'Arsonval type of galvanometer has just been brought out by Mr. Crompton which embodies many valuable improvements suggested by his long experience with this class of instrument.

The base of the galvanometer is of solid brass, insulated and levelled by means of ebonite-headed screws, the heads

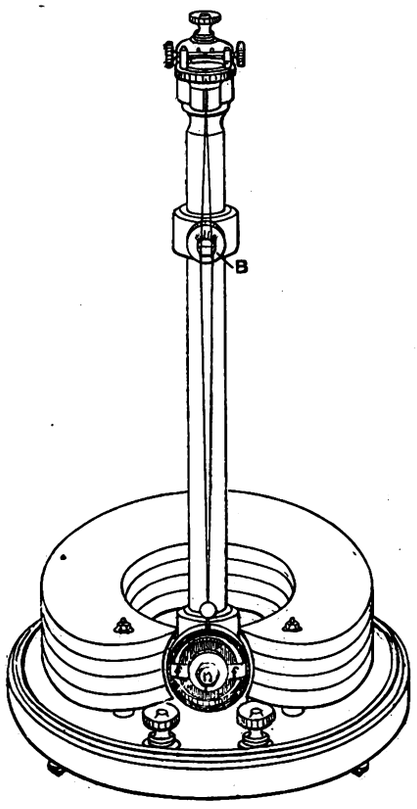

FIG. 1.—Front Perspective View of Galvanometer, with Case removed.

having the section of an inverted pyramid with sharp steps easily wiped at any time and affording exceedingly high insulation. The permanent magnet, it will be seen from Figs. 1 and 2, is of nearly true horseshoe shape, and is composed of four sections, which are secured to the base by three holding-down bolts.

The connecting wires are brought to the two terminals shown in Fig. 1 in the front of the instrument, and the circuit is taken thence to the bifilar attachment by a lead running up inside the central pillar. The details of the bifilar attachment at the top of the central pillar are given in Fig. 3. The attachment takes the form of two conical pins, P P, revolving in pillars, *p p*, which are diametrically placed upon an ebonite sleeve, E, having a rim with milled surface, and free to turn in the collar of the projecting arm A cast upon the main sleeve S encircling the cap C of the pillar. The sleeve S is free to revolve around the cap, and when properly adjusted is fixed at the side by the set screw *s*; the cap itself is capable of being raised and lowered by the milled nut N, shown at the top, and is prevented from turning by a set pin working in a slot in the pillar. The suspension wires, which are of phosphor-bronze, are secured to the pins by being passed through holes and plugged.

The sensibility and period of the instrument is altered by means of the device shown at B in Fig. 1. This consists of a thin slip of insulating material, which is carried by an arm attached to a sleeve which is free to move vertically or radially on the central pillar, and which is fixed, when properly set, by a screw at the side. Using the full sensibility of the galvanometer, this slip would lie parallel with the bifilar suspension; by setting the slip at right angles to the bifilar suspension, and raising or lowering the sleeve, both sensibility and period may be adjusted to requirements.

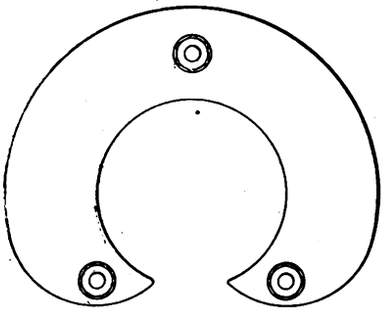

FIG. 2.—Plan of Magnet.

The coil is of copper wire, and is of the ring type. The utmost care has been taken to free the copper, silk, and other materials used, from all magnetic particles. The extreme importance of this has been pointed out by Prof. Ayrton, and all makers of galvanometers of this type are indebted to him for this. The coil is attached to the two hooks at the ends of the suspending wires by two metallic loops. The removal of one coil and the substitution of another is thus only a matter of a moment or two. Several coils can be supplied with each instrument; these weigh from 6 to 10 grammes, and have resistances ranging from 50 to 1,500 ohms. The coil is clutched, when travelling, between two light springs tipped with rubber. The front spring is shown at *f* in Fig. 1, also the nut *n* by which the springs are bent round on to the coil.

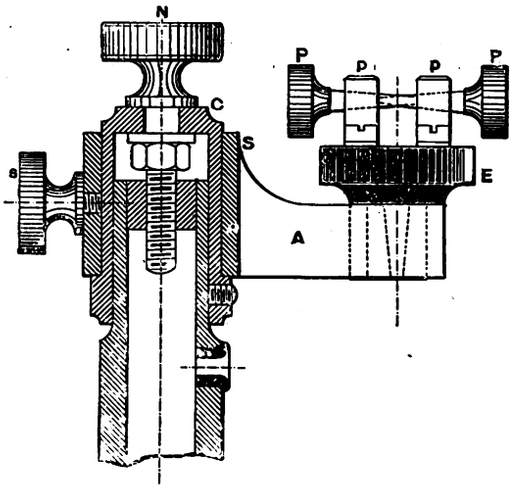

FIG. 3.—Bifilar Attachment. Sectional Elevation.

The whole instrument is protected by a brass guard ring. A portion of the front of this is cut away, and purest plate glass of thin section substituted. In some instances the glass screen is partially cut away, and a disc of microscopic film glass about $\frac{1}{100}$th of an inch thick is cemented over the opening. The whole is surmounted by a French glass shade.

The deflection ordinarily attainable is 10 scale divisions at a distance of 2,000 scale divisions, with the terminals of the instrument connected in shunt to $\frac{1}{100}$th of an ohm in series with 20,000 ohms, and a secondary cell, the P.D. over the $\frac{1}{100}$th of an ohm corresponding therefore to one-millionth of a volt, the resistance of the coil and its suspension being about 1,500 ohms.

THE BIRMINGHAM TECHNICAL SCHOOL.

The Technical Instruction and Local Taxation Acts of 1889 and 1890 have placed at the disposal of the municipal authorities throughout the country large sums of money, which, in most cases, have been expended in supporting the technical education movement; and the result has been that a great number of well-equipped institutions have been brought into existence during the last four years. The Birmingham Municipal Technical School, which is to be formally opened to-day by the Duke of Devonshire, is probably the finest of these new

FIG. 1.—Exterior View.

institutions existing in the country at the present moment. These municipal schools correspond in many respects with the large polytechnics with which Londoners are familiar, and of which there are now no less than eight in existence within the metropolitan area. But, although there are many points of resemblance, there are considerable differences too. While each of the London polytechnics maintains numerous classes in science and its technical applications, it also performs a similar function with respect to classes in music

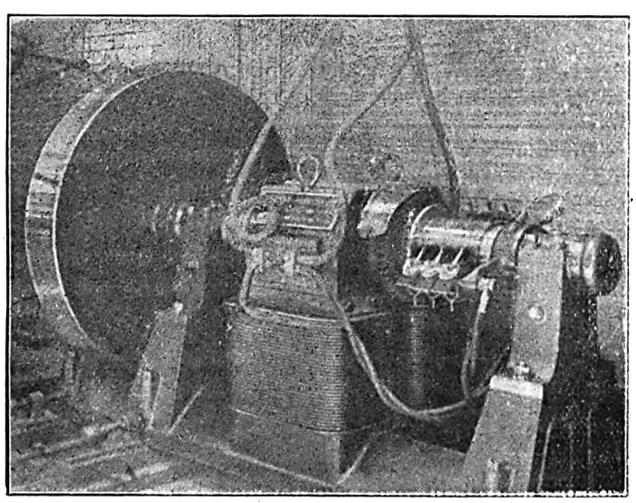

FIG. 2.—One of the Dynamos.

and in art, and with respect to classes in languages and commercial subjects. Moreover, in addition to all this, the athletic, recreative, and social functions of a London polytechnic are a most important part of its action. In the newer ones, it is true, less prominence is given to this side of the work, but it is notorious that in the older ones the social and recreative elements are relatively the most important of all. In Birmingham these different functions are not all undertaken by any one institution, and the purpose of the present Technical School is solely to provide instruction in science and its useful applications. Students in art subjects are already well provided for by the Municipal School of Art, which has been in existence for many years, and has earned a high and well-deserved reputation. Similarly, the Birmingham and Midland Institute provides high-class instruction in music and languages, and also performs many of the popular and social functions of a London polytechnic. Indeed, until four years since, this Institute possessed in addition a large number of science classes, all of which were transferred to the municipal authorities after the passing of the Local Taxation Act in 1890; and it was these classes which formed the nucleus of the present Technical School. While, therefore, the tendency in

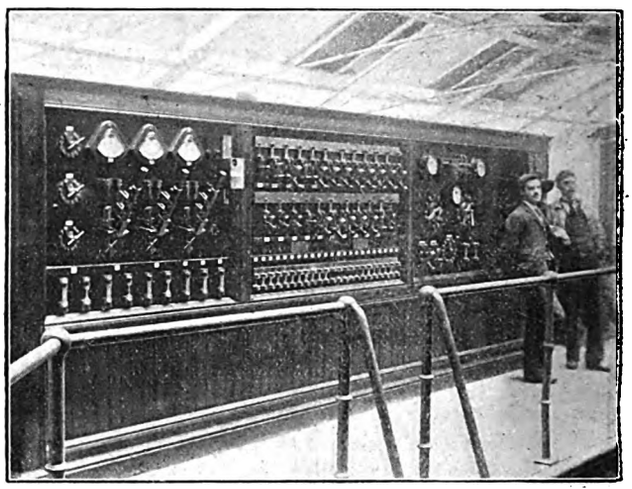

FIG. 3.—The Switchboard.

London has been rather towards the establishment of several institutions, each claiming all subjects as being within its scope; the tendency in Birmingham has been towards specialisation. The portion of the taxation money handed over to the Corporation for the purposes of technical instruction amounts in the case of Birmingham to about £10,000 every year; and the municipal authorities have wisely decided to devote this money towards the establishment and proper equipment of a single institution, rather than divide it among

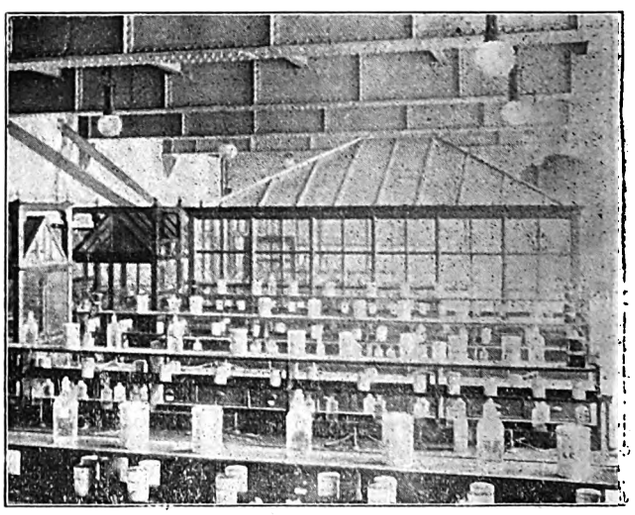

FIG. 4.—Metallurgical Laboratory.

a number of smaller schools placed in different parts of the town, and necessarily less completely equipped. The money thus provided, together with students' fees and the annual grants from the Science and Art Department, amounts in all to an income of about £12,000 per year available for the School, without resorting to the local rates, and means are thus provided for establishing and maintaining an institution of the first rank. The capital sum spent upon land, buildings, fittings, and plant of the new School amounts to £84,000,

Digitized by Google

including a sum of £6,000 for the electric lighting and power plant.

To electricians the most interesting feature of the School is the electrical installation. The building, of which an outside view is shown in Fig. 1, is very large, occupying an area 210ft. long by 120ft. wide. It is six stories high, its total floor area is 103,000 sq. ft., and it contains 134 rooms besides staircases, corridors and lavatories. The lighting is electrical throughout, and the machinery in the various workshops is electrically driven by 15 motors of various sizes, the aggregate power of which is 46 H.P. The lighting involves the use of over 800 glow lamps and 80 arcs. The motive power in the engine room is provided by three

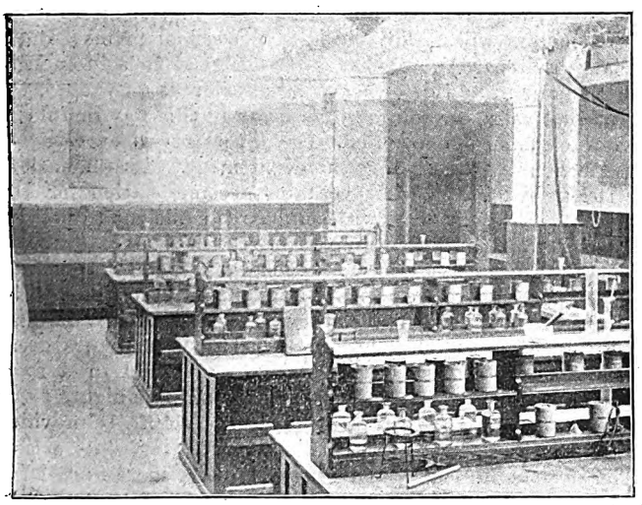

FIG. 5.—Electro-Metallurgical Laboratory.

Tangye gas engines running at 160 revolutions, and each capable of continuously generating 53 brake horse-power at that speed. Two heavy flywheels, 7ft. in diameter and 10in. wide, are attached to each engine. The dynamos are compound wound, made by Thos. Parker, Limited, of Wolverhampton, and can each generate 350 amperes at 113 volts, when running at 900 revolutions. To ensure steady running each dynamo is provided with three bearings, and a very massive flywheel 4ft. in diameter, having a solid rim 8in. by 8in. (see Fig 2). Compound

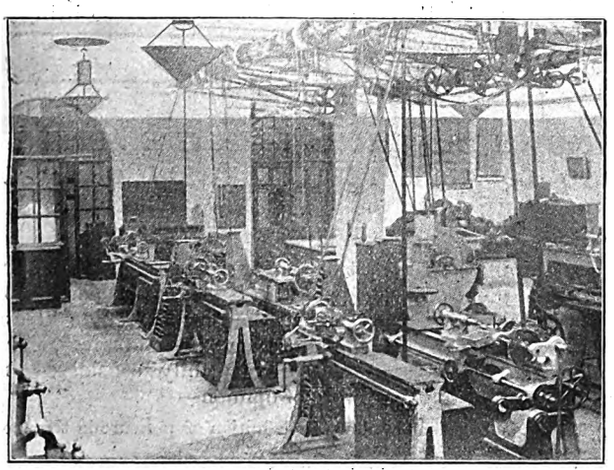

FIG. 6.—Iron Shop.

iron and leather pulleys, specially designed by the consulting engineers to prevent belt slip, are used with each dynamo.

Above the dynamos is a gallery carrying a handsome switchboard. This consists of four slate panels in a teak frame, and is shown in Fig. 3. The first panel contains the main dynamo switches and ammeters, a Kelvin voltmeter, and the regulating resistance switches in the shunt circuit of each machine. Each main switch interlocks with a smaller switch by means of which special connections are made enabling the three dynamos to be run in parallel without risk of reversal. The second panel of the board contains the switches and fuses for the motor and lighting circuits, and the third carries the charge and discharge ammeters and the regulating switches for the accumulator circuits, besides two other regulating switches used with a motor transformer in charging the cells. The fourth panel of the board carries two recording instruments by Richard Frères, used to continuously register the pressure and current in the accumulator circuit. At the end of the gallery is a four-unit motor transformer converting from 110 volts to 40 volts, and used to "boost" up the voltage to the extent necessary to charge the 58 "E.P.S." cells provided as the storage plant. These

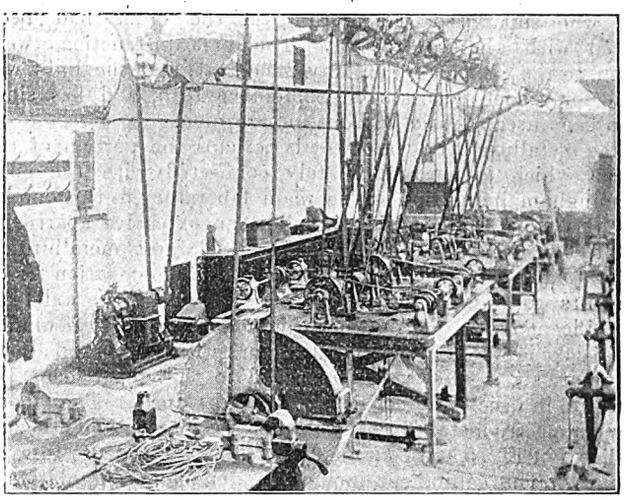

FIG. 7.—Brass Shop.

cells are of the central station type, in lead boxes, and each contains 34 plates. They are placed in an apartment closely adjacent to the engine room. A special change-over switch is provided on the switchboard for connecting the motor transformer with leads to the electrical department of the school, so that when not wanted for charging purposes it can be used for supplying current to the dynamo room at a voltage differing from that of the lighting circuit. The storage capacity of the accumulators is sufficient to light the corridors, staircases

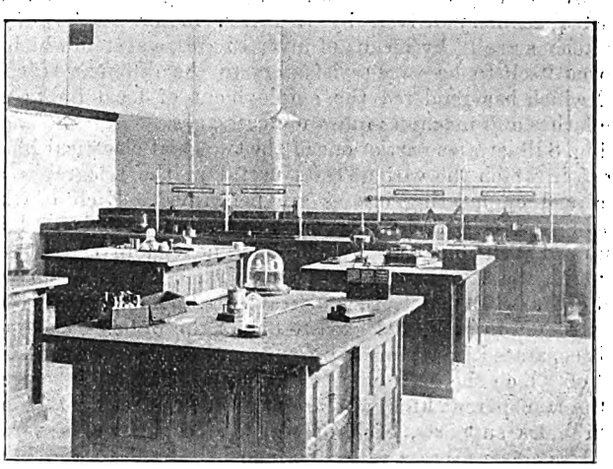

FIG. 8.—One of the Electrical Laboratories.

and certain other lights after the engines have stopped, and to take the day load.

The glow lamps are of the obscured type made by the Edison-Swan Company, and are of three different candle-powers, viz., 8 c.p., 16 c.p. and 50 c.p. The arc lights are of Crompton's make. Some are of the ordinary type, with diffusing globes, but the majority are of their inverted type, with the lower carbon as positive, throwing all the light up to the ceiling for subsequent diffusion downwards.

Digitized by Google

These inverted arcs, which were introduced at the suggestion of the principal of the School, have proved very suitable for the workshops and drawing offices. In fact, the conditions which usually obtain in an institution of this kind are specially favourable to the success of this particular system of lighting. The walls and ceiling can easily be kept white, and the height of the room is as a rule about that which gives the best effect. Circumstances have hence conspired to make this method of lighting one of the most striking and successful features of the installation. The motors used in the workshops were all supplied by Messrs. Crompton. The contractors for the entire installation were Messrs. B. Verity and Sons, and the consulting engineers were Messrs. Henry Lea and Thornbery, of Birmingham, who drew up the specifications and plans, and who supervised the work after the order had been placed with the contractors. The first instructions were given to the contractors on May 22nd last, and the light was used for school purposes on September 16th, and has since then been used nightly without interruption.

The metallurgical department is perhaps the portion of the school which is most intimately connected with the chief Birmingham industries. The main laboratory in this department is illustrated in Fig. 4, and is an extensive apartment 100ft. long by 45ft. wide. It is the largest metallurgical laboratory in the country, and contains accommodation for 80 students working at one time. Alongside one of the walls is a magnificent range of 34 furnaces, in addition to 28 gas muffles and 6 coke muffles for experimental work with metals and alloys. There are six smaller rooms attached to this department, the students in which number nearly 200 individuals. The laboratory for electro-metallurgy and for metal colouring and bronzing is shown in Fig. 5 and contains benches for 50 students to work at once. The equipment includes a dynamo, accumulators, a large number of depositing vats, and a very complete system of electrical connections between these and the students' benches. The chief laboratory covers an area of 56ft. by 30ft., and there are four smaller rooms attached. There are eight well-equipped workshops for plumbing, iron and steel work, brassfounding, carpentry, pattern making, metal plate work and electrical instrument making. As many as 525 students attend these workshops every week, and of these nearly 200 work in the iron and steel shop, which is illustrated in Fig. 6. The lathes and machines here are driven by a 7 H.P. Crompton motor, and the area of the shop, including the adjoining smithy, amounts to 3,500 sq. ft. The brass shop is shown in Fig. 7, and is abundantly equipped with lathes and other machinery driven by a 4 H.P. motor. Most of the workshops are lit by means of inverted arcs, a system which has proved itself to be very satisfactory to the different teachers, and which has rendered the employment of local lights near the lathes and machines quite unnecessary.

Fig. 8 illustrates part of one of the two chief electrical laboratories in which the various tests useful in the telegraphy and electrical engineering classes are performed. Each of these laboratories is 44ft. long by 22ft. wide, and is well fitted and equipped with apparatus. The chief novelty in the arrangements of the laboratory is a special bench for galvanometers and other delicate reflecting instruments. This is very solidly constructed in teak, and fixed to one of the walls of the room. It is separated by a gangway from another bench parallel to it, and on which the galvanometer scales are fixed. These are all of the transparent kind, and are suspended in suitable frames from brass supports, each of which is capable of a vertical adjustment on a brass pillar permanently fixed to the bench. The measuring apparatus used by the students is arranged on the bench in front of the scales, on the side remote from the reflecting instruments. The light which provides the ray is produced by a glow lamp fixed on the galvanometer bench, and the ray is thrown on to the reflecting instrument by a suitably inclined mirror.

The dynamo and battery rooms are conveniently near the laboratories. The battery room contains 40 small cells discharging at 7 amperes, and 12 larger ones, from each of which 120 amperes can be obtained. The dynamo room is as yet only partially equipped, some of the machines intended for it being involved in the recent disastrous fire at the Crompton works, just after they had been tested preparatory to sending them to their destination. The equipment, when complete, will include two 7 H.P. continuous-current machines, belt-coupled through shafting, one dynamo being shunt wound and the other compound, the series coil being led to independent terminals. There will also be two direct-coupled 3 H.P. machines, one series and the other shunt wound, with the latter suspended in a cradle in such a manner that the torque transmitted by one machine to the other can be registered while running. In addition to these there will be four machines of 5 H.P. each, forming two pairs of machines, each consisting of a continuous-current motor direct coupled to an alternator, and the arrangements being such that the two pairs of machines can be either run separately or coupled together with any required phase difference between the alternators. All the motors will be driven from the school mains from a special switchboard which has been designed so as to enable each machine to be run either as a motor or as a dynamo, the educational value of each machine being in this way doubled.

In the chemical department the laboratory is even larger than that in the metallurgical department. Its dimensions are 104ft. by 57ft., and it contains accommodation for 104 students working at once, with cupboards sufficient to provide one each for six times that number of students.

The drawing classes at the school are remarkably well attended, since there are over 600 students in these alone. The three rooms for the machine drawing classes occupy an area measuring 46ft. by 50ft., and are used on five nights every week. The geometrical drawing classes are held in a room measuring 60ft. by 20ft., and this is also used five nights every week. A separate room measuring 60ft. by 40ft. is provided for the drawing classes in the subject of building construction.

The students in the school already number more than 1,700 individuals, and the total number of entries in the various classes this session exceeds 3,500. These figures are exceeded by the London polytechnics, but it must be remembered that in most cases only a small proportion of the students at these institutions attend the science and technical classes, whereas the Birmingham School confines its work entirely to such matters. The number of entries in some of the chief groups of subjects are as follows: drawing classes, 664; chemistry, 623; physics and applied electricity, 545; workshops, 525; metallurgy and electro-metallurgy, 474; engineering lectures, 450. The three chief departments of the school, viz., the chemical, metallurgical and electrical departments, are respectively directed by Mr. C. J. Woodward, B.Sc., Mr. A. H. Hiorns and Dr. W. E. Sumpner, the last-named also being the Principal of the School.

REPORT OF THE SPECIAL COMMITTEE APPOINTED TO CONSIDER THE DEFINITION OF "LOW PRESSURE."

The following is the report of the Committee appointed by the Board of Trade to consider whether it was desirable that the limit of low pressure, as defined by the Board of Trade Electric Lighting Regulations for the protection of public safety, should be altered. The Committee, having duly considered the question referred to them, were of opinion—

(I.) That it is expedient to alter the definition of pressure in the above-mentioned Regulations as follows, viz.:—

Firstly, omit the following words—"pressure on any alternating current system being taken to be the equivalent of pressure on a continuous current system when it produces an equal heating effect if applied to the ends of a thin stretched wire or carbon filament."

Secondly, in place of paragraphs (*a*), (*b*), and (*c*) substitute the following, viz.:—(*a*) Where the conditions of the supply are such that the pressure may at any time exceed 500 volts if continuous, or 250 volts if alternating, but cannot exceed 3,000 volts whether continuous or alternating, the supply shall be deemed a high-pressure supply. (*b*) To be worded as existing. (*c*) Omitting "or the equivalent of 3,000 volts."

(II.) The Committee further advise that the following amendments should be made in the proposed Regulations, viz.:—

(*a*) Regulation 1 to read as follows:—"Save as hereinafter provided, the pressure of a supply delivered to any consumer shall not exceed 250 volts at any pair of terminals."

Digitized by Google

(*b*) Regulation 31 add: "No such conductor shall be at a higher pressure than 300 volts from earth."

(*c*) Regulation as to Supply, No. 6, omit the words "or less than 45 volts if continuous, or the equivalents thereof respectively if alternating." In place of "150 volts" read "250 volts." Add at the end the following proviso—viz., "Provided that no change shall be made in the pressure of the supply to any consumer in consequence of the issue of these Regulations except with his consent."

(III.) With reference to the suggested alteration to Regulation as to Safety, No. 31, the Committee are of opinion that to enable the use of 500 volts continuous pressure between the outer conductors of a three or five-wire system with bare conductors laid in conduits, the Board of Trade may give a provisional sanction to an earth connection being applied to one point of the middle conductor in any case in which they are satisfied that a high insulation is maintained on all other points of the system, and that suitable and sufficient means are provided for the immediate detection, localisation and correction of any fault of insulation.

(IV.) The Committee consider that in making the above suggestions they have indicated clearly how, in their opinion, the question of limitation of pressure should be treated to adequately secure the safety of the public, and to meet the requirements of Electric Lighting Undertakers and the convenience of their customers. They do not, however, wish to insist upon the exact wording suggested, and would leave the final drafting of these amendments, and any consequential verbal amendments of the Draft Regulations, in the hands of the Board of Trade.

8, Richmond Terrace, Whitehall, December 2, 1895.

THE BEHAVIOUR OF TRANSFORMERS UNDER THE INFLUENCE OF ALTERNATING CURRENTS OF DIFFERENT WAVE FORMS.*

BY DR. G. ROESSLER.

(Concluded from page 187.)

The Difference in the Primary Currents.

The investigation with the transformer has shown that for constant R.M.S. of the primary potential difference the R.M.S. current is smaller with pointed than with flat curves. The general explanation of this difference is not easy, as the relation between the variations of potential difference and current, as above shown, are very complicated; this explanation requires a general method of calculating the current from the potential difference. In what follows this is investigated on the assumption that the secondary circuit of the transformer is open. The no-load current can be most easily calculated by first obtaining B_{max}. We then have

$$B_{max}=\frac{c}{4 n_1 \nu s}\sqrt{M(E p_1^2)}.$$

If we then suppose that the demagnetisation of the iron by the action of the alternating currents at 41 ∿ was so conducted that we could measure the magnetising force H_{max} which B_{max} requires, by magnetometer or by ballistic galvanometer, we should have the equation

$$H_{max}=0{\cdot}4\pi\frac{n_1}{l}J_{max},$$

from which, in closed magnetic circuit transformers, J_{max} could be calculated. Hence $\sqrt{M(J_0^2)}$ can be obtained from the relation

$$K=\frac{\sqrt{M J_0^2}}{J_{max}},$$

which, like *c*, depends only on the shape of the current curve, and which, for the current curves of the two machines, has the value K=0·515 (Ganz machine), and K=0·546 (Wechsler machine). If this conclusion be correct, the great difference of the no-load currents with the two machines can be at once explained, since B_{max} is proportional to *c*; hence for peaked potential curves there are much smaller values of H_{max} and J_{max}, and thus also of $\sqrt{M(J_0^2)}$, than for flat curves, and since also K is smaller for pointed than for flat curves.

To decide the question of the calculation of $\sqrt{M(J_0^2)}$ from these simple considerations, the magnetising curves of the transformer iron were taken with the ballistic galvanometer, and also from the values of $\sqrt{M(E p_1^2)}$ and the corresponding values of $\sqrt{M(J_0^2)}$, from Table VI., by the aid of the formulæ

$$B_{max}=\frac{c\sqrt{M(E p_1^2)}}{4 n_1 \nu s},$$

and

$$H_{max}=0{\cdot}4\pi\frac{n_1}{l}\frac{\sqrt{M(J_0^2)}}{K},$$

from which B_{max} and H_{max} were calculated. If the above method of calculation of $\sqrt{M(J_0^2)}$ from $\sqrt{M(E p_1)^2}$ is exact, the curves giving $B_{max}=f(H_{max})$ from the measurements with both machines must agree among themselves, and with the curve obtained by the ballistic galvanometer measurements.

For the ballistic galvanometer measurements the transformer was magnetised by accumulators connected to the primary, while the ballistic galvanometer was connected to the secondary. In order to get accurate absolute values of B_{max}, the reading of the galvanometer was checked carefully by a Reichsanstalt standard. The value of the "constant" is calculated thus: A current $J=1{\cdot}292\times10^{-6}$ amperes, given by the standard, gave a reading *a*, such that $\tan a=0{\cdot}04524$; also $c=\frac{J}{\tan a}=2{\cdot}857\times10^{-5}$. The periodic time was T=11·97sec. The log. dec. λ was so small that $e\frac{\lambda}{\pi}\tan^{-1}\frac{\pi}{\lambda}$ never differed ½ per cent. from unity. Hence for a momentary discharge through the ballistic galvanometer the quantity

$$Q=c\,.\,\frac{T}{n}a$$
$$=2{\cdot}857\times10^{-5}\,\frac{11{\cdot}972}{\pi}a.$$

If a reading *a* is produced by suddenly reversing the primary current J, then the magnetic induction

$$B=\frac{w\,Q\,10^8}{2 s n_2}$$
$$=\frac{w}{2\times20{\cdot}19\times265},$$

in which *w* is the total resistance in the galvanometer circuit; hence, finally,

$$B=20{\cdot}36\,w\,.\,a.$$

The measurements gave the following magnetisation curve:—

Table VII.—*Magnetisation Curve of the Transformer, Measured with the Ballistic Galvanometer.*

H.	B.	H.	B.	H.	B.
0·770	116·3	7·308	9,138	16·92	13,780
1·532	624·4	8·232	9,934	18·52	14,090
3·330	3,932	11·52	11,930	21·34	14,640
4·800	6,502	14·26	12,880	...	...

Also, the calculations of B_{max} and H_{max} from the values of $\sqrt{M(E p_1^2)}$, and $\sqrt{M(J_0^2)}$ from Table VI., give the results:—

Table VIII.—*Magnetisation Curve of the Transformer, Deduced from the Alternating-Current Measurements.*

Ganz machine.		Wechsler machine.	
H_{max}.	B_{max}.	H_{max}.	B_{max}.
4·012	2,839	4·056	3,855
5·136	3,982	5·566	5,873
6·246	5,217	7·281	7,830
7·635	6,742	9·098	9,410
9·142	8,109	13·12	11,620
11·54	9,477	17·98	13,280
15·18	10,940	30·94	15,530
19·03	12,320	...	...
24·33	12,910	...	...
28·96	13,590	...	...
32·95	14,150	...	...

Fig. 23 shows this graphically. The upper curve gives the result of the ballistic measurements, the middle the results of the measurements with the Wechsler machine, and the lower those for the Ganz machine. The three curves do not lie together, but differ somewhat widely.

For this result there are several reasons. First, it must be remembered that the same induction B in the iron, if produced by alternating currents, requires a greater current than with continuous currents, since eddies are produced. These variable currents in the iron increase the primary current, for the same reason that it is increased by short-circuiting the secondary. The magnetising curves measured with alternating currents must therefore fall below those with direct currents. The difference is even greater than shown by the above measurements, since with the ballistic galvanometer only those lines are measured which are produced in the secondary when the primary is excited, whereas in the alternating measurements the total number of lines cut by the primary itself is measured. Thus, on account of magnetic leakage, the induction measured by the ballistic galvanometer is about 2·5 per cent. too small.

* "Das Verhalten von Transformatoren unter den Einflusse von Wechselströmen verschiedenen periodischen Verlaufs." A Paper read at the third annual meeting of the Verband Deutscher Electrotechniker, Munich July 6, 1895.

Digitized by Google

The difference between the two magnetisation curves, measured with the alternators, is explained by the difference in the intensity of the eddy currents. In an earlier part of the Paper it is shown, theoretically and experimentally, that peaked potential difference curves for equal values of B_{max} give greater eddy current loss than flat curves. The facts shown above, that alternating currents with peaked potential difference curve require a greater value of J_{max} to produce a given value of B_{max} than steady currents, and than flat curves, thus hold universally.

There still remains the question whether the explanation of the observed differences is due to so-called magnetic viscosity. By this term, as is well-known, Ewing has denoted that property of the iron which causes it to take a definite time to take up the magnetisation induced by the magnetising force. Since, in the present case, it takes about $\frac{1}{100}$th of a second for the current to alter from its zero to its maximum value, it is possible that the magnetisation does not reach its full value in so short a time, and that since the given value of $\sqrt{M(E p_1^2)}$ assumes a definite value of B_{max}, the current J_{max} required is greater than that given by the magnetisation curve. If the influence of magnetic viscosity were very great, the difference between the ballistic magnetisation curve and all alternate-current curves would be nearly the same. The difference of these curves among themselves, however, is almost as great as their variation from the ballistic curve. This agrees with Ewing's observations that the viscosity for ordinary periodicities is not important. The correction for magnetic leakage on the ballistic measurements does not affect this conclusion.

The results given for the no-load current J_0 can be got at once from the primary current J_1, when loaded, since it is approximately

$$\sqrt{M(J_1^2)} = \sqrt{M(J_0^2)} + \frac{n_1}{n_2}\sqrt{M(J_2^2)}$$

In general the primary current cannot be so simply calculated from the primary potential difference as given above on account

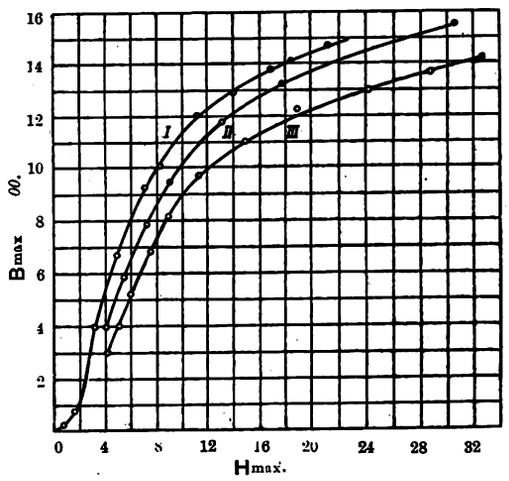

FIG. 23.—Magnetisation Curves. I. Ballistic Galvanometer. II. Wechsler Machine. III. Ganz Machine.

of the influence of eddy currents. The diminution of B_{max}, for peaked forms of potential difference curve, as compared with flat curves, is accounted for in the foregoing extreme case by the increase of J_{max} by eddy currents, so that in general *for equal* $\sqrt{M(E p_1^2)}$, *the current* $\sqrt{M(J_1^2)}$ *is always smaller for pointed than for flat potential difference curves.*

The consideration of eddy currents by the predetermination of $\sqrt{M(J_1^2)}$ is a problem of great difficulty; an accurate calculation from $\sqrt{M(J_1^2)}$ is also impossible. On account of the difficulty, that the true no-load current of a transformer is always greater than that calculated from the magnetisation curve, one introduces, in the calculation of this "magnetising current," a second current in quadrature, which is called the energy component, and from the above consideration has the value $J_A = \frac{C}{Ep}$.*

If we denote the magnetising current by $J\mu$,

$$J_0^2 = J\mu^2 + \left(\frac{C}{Ep}\right)^2.$$

This method of calculation gives the following results: From the equation for the load of the alternate current, $A = Ep\,J\,F$, which for sine alteration of the potential difference and current takes the form $A = Ep\,J\cos\phi$,

where ϕ is the phase difference between potential difference and current, the part to be considered is only the part $J_A = J_0\cos\phi = \frac{A_0}{Ep}$. With close approximation, also, $J_0\cos\phi = \frac{C}{Ep}$. If we consider this part as a component of the current, then, for the calculation of the total current a second component, $J_0\sin\phi$, is required, which is in quadrature with the other, and has the peculiarity that it has no power factor. This second component, $J\mu$, has the property of producing the alternating flux without loss of energy; we find it as above from the total value J_0, and from the magnetisation curve of the iron, after one has calculated B_{max} from $\sqrt{M(E p_1^2)}$. The conclusion, that $J\mu$ so calculated has no power, appears to me incorrect, since the correct calculation of $J\mu$, by the use of the quantities c and K, which depend on the shape of the potential difference and current curves, also depends upon the form of these curves, which are known by the hysteresis curve of the iron. From this it is seen that the current $J\mu$ supplies the power in hysteresis itself, and it only remains to consider the loss in eddy currents. If we only calculate with those values of c and K which hold for sine curves we naturally get a greater error, since Ep_1 and J_0 cannot simultaneously have this form. That the building up of J_0 from these two components is not theoretically justifiable is shown by the above investigation, since if, for both potential difference curves, the current $J\mu$ is corrected by adding a component in quadrature, the increase of $J\mu$ for peaked potential difference curves would be smaller than for flat ones, since the total power A_0 is smaller. The investigation shows that the correction of $J\mu$ for peaked curves must be greater; the assumption that the eddy currents alone cause the increase of $J\mu$ gives a satisfactory explanation.

Since the knowledge of a method, even though only empirical, of calculating J_0 from $J\mu$ is of the greatest importance, in (Table IX.) the current is calculated by this method from the potential difference and power given in Table VI., and the measured values compared.

The calculated values are in the last column but one, the observed values in the last.

It is known that, with the sine variation of the Wechsler machine, the assumption is much closer than with the pointed curve of the Ganz machine. In both cases the calculated values are too small, although the component $J_A = \mathfrak{E}/Ep$, which is added to $J\mu$, contains the whole power, whereas in practice $J\mu$ should only be increased by the eddy-current loss. This apparent contradiction is explained by remembering that J_A is at right angles to $J\mu$, and that when it is small compared with $J\mu$ the total current, $J_0 = \sqrt{J_A^2 + J\mu^2}$, is very little increased. For the Wechsler machine, the assumption is sufficiently correct for the transformer maker; for normal the potential difference of the transformer of 60 ν, the calculation gives, for example, $J_0 = 1{\cdot}997$ amperes, and measurement $J_0 = 2{\cdot}103$ amperes. This result confirms almost exactly the method of calculation in the case of sine variations.

The Differences of the Secondary Potential Differences.

The investigation on the transformer has shown that for given R.M.S. of the primary potential difference the secondary potential difference was the same with both machines at no-load. When loaded a difference arose in this way, that, with the pointed Ganz curve, the drop in secondary potential difference as the load increased, was more marked than with the sine curve of the Wechsler machine. The difference at full load was about 1 per cent. But, on the contrary, with equal secondary current the primary current, and hence also the ohmic potential difference, drop is greater with the Wechsler machine, hence the difference in the secondary potential difference can only be explained by a difference in the magnetic leakage. The measurements also show that the leakage of the loaded transformer is greater for pointed than for flat curves. This result can be easily explained by the magnetisation of the iron.

If we denote the maximum value of the flux which the primary current induces in the primary coil by N_1, and the maximum flux that the secondary current induces in the same coil by N_2, then all the lines N_1 do not pass through the second coil, nor do all the lines N_2 cut the first coil. On account of the magnetic leakage, let the quantities leaking be $Z\,N_1$ and $Z\,N_2$; then the first coil induces $(1-Z)\,N_1$ in the second, and the second induces $(1-Z)\,N_2$ in the first. As in the case of the currents, the phases of the inductions are opposite, and, at higher loads, the maximum values are simultaneous.

Hence the total lines cut are

$$N_1 - N_2(1-Z) \text{ by the primary,}$$

and

$$N_1(1-Z) - N_2 \text{ by the secondary coil,}$$

* Here and henceforth the R.M.S. of potential difference and current and the mean power are denoted by Ep, J, and A respectively.

* $J\mu$ is calculated from the equation

$$H_{max} = 0{\cdot}4\pi\,132\,\frac{J\mu}{K}$$

from which, for the Ganz machine, $H_{max} = 6{\cdot}61\,J\mu$,

Wechsler machine, $H_{max} = 6{\cdot}24\,J\mu$.

H_{max} is found from the ballistic magnetisation curve.

and the R.M.S. of the induced E.M.F.'s are

$$\sqrt{M(e_1^2)}=\frac{4\nu n_1}{c}(N_1-N_2+N_2Z),$$

$$\sqrt{M(e_2^2)}=\frac{4\nu n_2}{c}(N_1-N_2-N_1Z).$$

The transformation ratio has then the value

$$\frac{\sqrt{M(e_2^2)}}{\sqrt{M(e_1^2)}}=\frac{n_2(N_1-N_2-N_1Z)}{n_1(N_1-N_2+N_2Z)}.$$

This is smaller than $\frac{n_2}{n_1}$, and falls off with increasing values of N_1 and N_2—that is, with increasing current and load on the transformer. The quantity must be greater, the greater the values N_1 and N_2 are in comparison with their difference N_1-N_2.

These facts explain the difference of the behaviour with pointed and flat curves. For the same load of the transformer, and also for equal values of $\sqrt{M(J_2^2)}$, J_{2max} and J_{1max}, and thus also N_1 and N_2, are greater for pointed curves than for flat, and at the same time N_1-N_2 is smaller, since the resultant magnetisation B_{max} of the transformer iron, as has been already shown, for the same value of $\sqrt{M(Ep_1^2)}$, is always smaller for pointed than for flat potential difference curves.

Comparison and Extension of the Results.

The above investigations have indeed only been concerned with the behaviour of a transformer when loaded with glow lamps. The results are, however, applicable to the case of an inductive load. Firstly, the difference of the iron loss, it seems, remains the same, since this only depends on the value of the potential difference and its variation. Secondly, the difference of the primary current also remains the same if there is any lag between the secondary current and potential difference, since the equation

$$\sqrt{M(J_1^2)}=\sqrt{M(J_0^2)}+\frac{n_1}{n_2}\sqrt{M(J_2^2)}$$

holds with equal approximation from the conditions of constant magnetisation. Thirdly, the conditions given above for the difference of the magnetic leakage are independent of the kind of resistance in the secondary circuit, and hence the same difference of the potential difference drop is to be expected with inductive resistances. Measurements, in which the same transformer was loaded by a Swinburne "hedgehog" transformer, which gives a very great phase difference between primary and secondary current, have confirmed these conclusions. Particular cases of this investigation are yet to be settled. Considering these conclusions now, however, as generally accepted facts, we know that the use of peaked potential difference curves, so far as concerns the effect upon the power and the primary current, gives far better results than the use of sine or flat curves. These differences, which have been found in the above measurements, are of great importance in the economy of a transformer system, frequently even paramount. These great advantages of peaked potential difference curves, which tell in favour of their adoption, stand on the one side, and the greater secondary potential difference drop on the other. The percentage difference of this potential difference drop was, in the above cases, very much smaller than that of the differences of the primary current and power, and therefore it yields no important argument against the adoption of pointed curves if many transformers are on a secondary network whose potential difference can be regulated automatically from the central station. The regulation of the alternators necessitated by the increased fall of volts would not be appreciably augmented.

A much more important argument, however, against the pointed potential difference curve is the difficulty of insulation which the high maximum value of the potential gives rise to. In the above case, for the Ganz machine $c=\frac{\sqrt{M(Ep_1^2)}}{Ep_{max}}=0\ 285$, and for the Wechsler machine $c=0{\cdot}663$; hence, for equal values of $\sqrt{M(Ep^2)}$, Ep_{max} was three times greater in the first machine than in the second. In consequence of this fact it follows that for the Ganz machine, for the same insulation of the coils and leads, a much smaller value of $\sqrt{M(Ep^2)}$ is allowable than for the Wechsler machine. When one considers that the great advantage which a transformer possesses for the transmission of electrical energy arises from the ability to use very high line potentials, and that the use of this new advantage would cause great practical difficulties in the insulation, one finds an important objection to the pointed potential-difference curve.

For the consideration of these *pros* and *cons* the question arises: For what form of potential-difference curve is the power loss and the primary current least, if the insulation of the transformer and leads is the same in both cases? We will consider this question for the case of the secondary transformer of a power distribution.

Using the Ganz machine, the R.M.S. of the high potential, $\sqrt{M(Ep_1^2)}$, would be only the $\frac{1}{2{\cdot}3}$ part of the permissible value for the Wechsler machine. From the formula

$$B_{max}=\frac{c}{4n_1\nu s}\sqrt{M(Ep_1^2)},$$

we find that B_{max}, and also the iron loss, is not altered. Working with the Ganz machine would be in this respect the better. The diminution of n^1 to the $\frac{1}{2{\cdot}3}$ part for the same B_{max} and H_{max} by the equation

$$H_{max}=0{\cdot}4\,\pi\frac{n}{l}J_{max}$$

shows that $\sqrt{M(J_1^2)}$ must be increased to 2 3 times its value. If the primary current for the same high potential difference, $\sqrt{M(Ep_1^2)}$, was the same in both cases, then, by the diminution of $\sqrt{M(Ep_1^2)}$, for the Ganz machine, an increase of the loss in the primary winding and in the high-potential leads of $2{\cdot}3^2=5$-fold would result. For higher loading of the transformer, this result would be correct; on open circuit the no-load current for the Ganz machine for the same $\sqrt{M(Ep_1^2)}$ stands in the ratio of $\frac{1{\cdot}474}{2{\cdot}104}=0{\cdot}7$. By the diminution of $\sqrt{M(Ep_1)^2}$ the no-load current with the Ganz machine $=2{\cdot}3\times0{\cdot}7=1{\cdot}6$ times that with the Wechsler machine, and the loss in the high-potential leads $=1{\cdot}6^2=2{\cdot}6$ times as great. The cost of the energy with the Ganz machine would be considerably the higher, under all loads, if the insulation remained the same.

In general the adoption of one or the other machine must be based on the load diagram of the locality, and on the length of the leads. If power is required which during the greater part of the day takes only a small portion of its maximum value, as in the case of a central station in a town which gives power and light to many consumers, then the peaked potential curve would probably give the greater economy. For transmission of power to long distances the use of flatter potential difference curves is to be recommended.

It is to be remarked that in the above considerations the assumption is made that for the expression of the insulation only the value

Digitized by Google

$E p_{max}$ is of importance. It is, however, not impossible that with the use of higher potentials the insulation of the material is affected by time. In this case $E p_{max}$ would no longer be the quantity fixed by the insulation, but a value which approximates to the mean value of the pointed potential difference curve. Then the properties of pointed curves would be better than those given above.

These results are given for the behaviour of transformers alone. The smaller candle-power of arc lamps with pointed curves tends to throw the balance more to the side of flat curves. For a decision on all points an investigation on the behaviour of motors is necessary.

It should be observed that by the name "peaked" potential difference curve in what has gone before, is meant curves in which a part of the ordinates have a much larger value than all the others without thereby creating an actual sharp point. The typical properties of these "peaked" curves are given by the small value of $c = \frac{M E p_1}{\sqrt{M (E p_1^2)}}$, which arises from the lengthening of a few of the ordinates; hence all the properties of these curves may be obtained without an actual point. The curve of Fig. 24, for

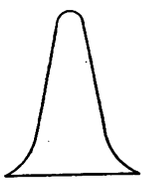

Fig. 24.

example, gives a very small value of c, yet the maximum does not become large. With a suitable form of curve of this type, one could remove most of the objections based on the higher insulation required without otherwise affecting the properties of these curves.

BATTERY CARS IN NEW YORK.*

The first attempt worthy of the name, to operate a street railway by storage battery cars in the United States, was carried out in 1889 by the New York and Harlem Railway Company in New York, on Fourth and Madison-avenues. These cars, ten in number, were equipped with Julien cells and were operated for several months, sandwiched in among the horse cars of the line. The reasons which induced the Company to abandon the further use of battery cars need not be here gone into, but suffice it to say that the question of cost of operation was not the principal one, and hence the Company has always looked with favour on the system and has ever since expressed its willingness to give fair trial to any system of this nature showing promise of success and quite free from the annoyance of patent litigation.

The time that has elapsed since the first attempt has served to bring about vast improvements in the storage battery, and, besides, the experience gained in storage traction work abroad served as a valuable guide to present American work in this field.

With these points in view, the Electric Storage Battery Company a short time since entered into negotiations with the New York and Harlem Railway Company for the equipping of a number of cars, with a view to a thorough determination of the feasibility of storage traction for its lines. These negotiations have resulted in the equipment of the cars, described below.

Starting out with the source of current, the storage battery, as a reliable piece of apparatus, and having constantly before them the troubles due to a mechanical nature with which previous attempts in this direction had been hampered, the Electric Storage Battery Company have been enabled to bring together a system which presents not only decidedly novel features, but in some respects radical departures from previous practice. First and foremost among these perhaps may be mentioned the method of handling the batteries, and the manner in which they are carried on the car. In all previous work of this class the batteries have in one way or another been carried within, or suspended from, the car body. Thus in the older forms the batteries were disposed under the seats for the passengers, and either let into the sides or through the platform ends of the cars. This in the first place required a heavy construction of the car body to withstand the strain of the additional weight imposed upon them. In the second place, this method required the seats to be wider than would otherwise have been necessary, and invariably resulted in an uncomfortable seat for the passengers, besides taking several inches from the width of the aisle running through the car. To this is to be added the fact that even with the greatest care exercised to prevent it the acid fumes were usually noticeable in the cars.

It has been sought to overcome part of these troubles by the methods of battery suspension adopted in the storage cars now in operation in Paris. There the batteries are contained in trays suspended from the car bodies between the two bogie trucks upon which the car rests. This, it is true, removes the batteries to the outside of the car body, but does not relieve the car body itself of the strain brought upon it by the weight of the battery, while it also subjects the passengers to the more pronounced shocks due to the increased mass of the car body loaded with batteries.

In the method adopted on the new Madison-avenue cars all these objections have been at once brushed aside by suspending the battery on the car truck. This relieves the car of all strain, so that it can be built as light as any horse car, and does away with all the other objections, and, as will be seen later, it permits of a facility in the operation and handling of the batteries rendered impossible by the methods employed heretofore.

In general terms the system of handling the batteries on the Madison-avenue line has been so arranged that all work which involves any movement of the batteries whatever is done below the level of the street, or of the ground floor of the car house. The batteries are assembled in trays mounted on four-wheel trucks; after being charged they are wheeled to a line of rails extending the complete length of the car house, and by means of turntables transferred to the track running parallel with the track above, upon which the cars are standing. The track upon which the cars enter the car house forms the top of a continuous pit. The small truck carrying the batteries is wheeled directly on to an elevator platform, which, when lifted, brings the batteries directly under the centre of the car at its proper place, and automatically suspends it on to the truck. The elevator with the small battery truck descends free of its load, ready for the next charged battery.

It will be noted that with the exception of the wheeling of the small trucks carrying the batteries, from their location while charging, no manual labour whatever is required in their handling, and even this part of the work it is intended shortly to free from manual work by a system of hauling cables, which will shift the battery trucks from one position to another automatically. The desire to press forward the equipment as fast as possible has prevented carrying out this detail for the present. This in brief will give a general idea of the methods employed. The details by which these methods have been worked out exhibit considerable ingenuity.

Each car is provided with 60 cells, grouped in two series of 30 cells each. The nine-plate traction type of chloride cells is employed, having a capacity of 400 ampere hours, and capable of sustaining a current discharge of 40 amperes for 10 hours. The cells weigh 95lb. each, making a total weight of 5,700lb. It is proposed, however, to put in service shortly a lighter type of battery, weighing only 2,400lb., which will, of course, necessitate more frequent change of battery. The connections of all the cells are burned together solid throughout, no screws or bolts of any kind being employed. The flexible cables are also burned on at all points, and are brought out to large brass plates on the sides of the trays, which form the terminals to which double shoes on the car make contact when the battery is lifted into place on the truck. The cells rest in a tray supported by four channel irons, which are bent up at the sides of the tray, and form ears from which the tray is suspended on the car truck. The outside measurement of the battery cells is 18in. high, by $5\frac{3}{16}$in. by $8\frac{1}{2}$in.

In order to prevent splashing, hard rubber grids are placed on the top of the cells, which break up any waves that may be formed by the vibration of the car.

As stated above, the trays containing the batteries rest on four-wheel trucks, running on twenty-one inch gauge tracks, which run at right angles to the main track running along the bottom of the pit, over which the street car runs on entering the car house.

The elevator employed in the Madison-avenue stables for this purpose is of the worm and worm-wheel type, and specially designed for this purpose, and built by the Sprague Electric Elevator Company. It can be worked from either side and the arrangement is such that it only requires to be started, stopping automatically at the proper point to land the batteries in the car truck overhead. It may be remarked also that by means of the elevator an armature can be readily removed from the motor.

The tray is provided with bevelled cast-iron corner pieces, so that even if it should be out of centre three-quarters of an inch when lifted on to the truck it will automatically slide into its proper place.

The truck upon which the batteries are mounted is of the Peckham type and of a special design. The Peckham standard truck is employed, but in addition thereto elliptical springs are placed at the ends on which the car body rests, together with extra spiral springs in the centre. The battery tray is hung from two cross-bars, the suspension bar being pushed forward under the ears of

* Abstract from the *Electrical Engineer* of New York.

Digitized by Google

the tray, and firmly held in place by a locking arrangement. The truck has a 7ft. 6in. wheel base with 30in. wheels.

In employing an elevator in the handling, it became necessary, of course, to provide means for automatically bringing the batteries in the centre of the car truck when raised. This has been provided for in an ingenious centring arrangement. The result is that should the car have come to a stop not directly above the centre of the elevator, the batteries will nevertheless be guided to the centre of the car by guide bars. This arrangement, it will be readily seen, economises greatly in time and obviates the necessity of any exceptional vigilance or skill on the part of the motorman in bringing his car to a stop.

The motors with which the truck is provided are of the General Electric "800" type, wound for a maximum of 24 miles an hour, and hence revolving at a greater speed than is usually employed on cars of this type. This winding was selected in order to effect as high an average efficiency of motor as possible with the varying potential employed. In practice it is not proposed to run above a speed of 12 miles an hour. Contrary to usual practice, the motors are turned toward the outside of the axles. This arrangement became necessary in order to allow of sufficient room for the insertion of the battery trays.

The "K.S.B." controller of the General Electric Company is employed, giving six combinations. These are: (1) batteries in parallel, motors in series; (2) same, with field shunt; (3) batteries in series, motors in series; (4) same, with field shunt; (5) batteries in series, motors in parallel; (6) same, with shunt.

When the trays are lifted into position on the truck, the terminal plates at their sides are brought up against double contacts at each terminal plate, so as to insure the absolute continuity of circuit. These double-contact shoes are pressed forward by steel springs, which, however, do not carry any current.

The car bodies employed are the widest built by this Company. The woodwork is no heavier than that of the ordinary horse car, and the whole car has an air of lightness about it in strong contrast to the previous types of storage battery car bodies. It is lighted by two three-light clusters, one connected to each set of batteries, so that light will always be available.

At the present time the current for charging the batteries is obtained from a 13½ kilowatt General Electric generator, driven by an Otto gas engine, but there will shortly be erected in addition to this a 30 kilowatt Eddy generator, belted direct to a 36 H.P. Otto gas engine.

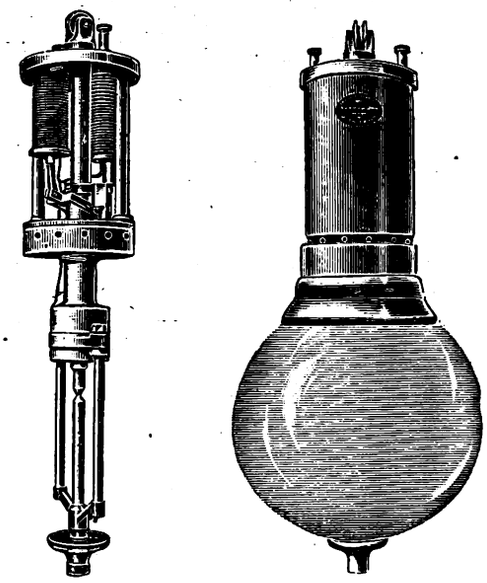
The charging switchboard is arranged for five circuits. At the top are placed the main ammeter and the voltmeter and below these the ammeters for the individual charging circuits, followed by handles for operating the resistance in each charging circuit, for obtaining uniformity of charge. At the bottom are placed the main dynamo switch and the rheostat for regulating the field of the generator and the overload and underload switches.

At the present time two cars are in operation on the Madison-avenue line, and these will be subjected to a series of tests which will determine the future course of the Railway Company, looking to the adoption of the storage battery system for its lines.

Theories of Electrolysis.—In the current number of *Science Progress* Mr. C. Dampier Whetham summarises existing theories of electrolysis. Starting with the application of Ohm's law to electrolytes, he discusses the evidence which Kohlrausch educed in regard to the specific character of ionic velocities. The hypotheses of Arrhenius, Ostwald and others concerning dissociated ions are next considered, and a number of interesting tables have been compiled by the author bearing upon the coefficient of ionisation and constants of affinity of a number of electrolytes. The dependence of general physical properties, such as the osmotic pressure, freezing point, &c., upon the electrolytic characteristics of the liquid are discussed in relation to the researches of Mr. H. C. Jones on this subject. From established data, the author proceeds to summarise the hypothesis in regard to the dissociation accompanying the solution of highly stable solids. In regard to this branch of the subject he arrives by independent reasoning at the conclusions: "That pairs of opposite ions must be separated, and the ions exist free from each other's influence, and, secondly, that there must be a tendency towards the formation of more or less stable molecular aggregates between salt and solvent." The apparent contradiction involved in these two conclusions is got rid of by the fact that "since it is evident that one salt molecule can influence a large number of water molecules, it follows that the chemical forces are very far-reaching."

THE "I.R." ARC LAMP.

The accompanying illustration shows the general construction of the Richardson "I.R." arc lamp, which is the invention and manufacture of Mr. A. W. Richardson, of Patricroft. A glance at the illustration shows that it is of the differential rocking-lever type, the lever directly actuating a central tube, to which the feeding gear is fixed. This gear is fitted in a box below the lamp bottom plate. Carbons of equal size are used for the top and bottom, and it is the practice to use the short end of the positive as a negative



The "I. R." Arc Lamp.

when re-carbonning. It is claimed that this is an advantage, though it might be difficult to persuade most arc lamp makers that it would be a good thing to abandon carbons of unequal diameters and lengths in continuous-current lamps. The maker of the "I.R." lamp considers it advisable to reduce the waste from two ends to only one in the manner indicated. The lamp is made in ordinary sizes to take from 5 to 12 amperes, giving from 500 to 2,000 nominal candle-power.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, December 13th.

PHYSICAL SOCIETY.

5 p.m. Meeting at Burlington House. Papers to be read: (1) "A Mechanical Device for Performing the Temperature Corrections of Barometers," by Dr. Shield; (2) "On the Existence of Earth-Air Electrical Currents," by Prof. Rücker.

INSTITUTION OF ELECTRICAL ENGINEERS.

7 p.m. for 7:30 p.m. Annual Dinner at the Freemasons' Tavern.

MONDAY, December 16th.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture III.: "Mechanical Road Carriages," by W. Worby Beaumont.

TUESDAY, December 17th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be read and discussed: "The Design and Testing of Centrifugal Fans," by Hammersley Heenan and William Gilbert.

WEDNESDAY, December 18th.

ROYAL METEOROLOGICAL SOCIETY.

7:30 p.m. Ordinary Meeting at the Institution of Civil Engineers, 25, Great George-street, Westminster.

SOCIETY OF ARTS.

8 p.m. Fifth Ordinary Meeting. Paper to be read: "Machines for Composing Letterpress Printing Surfaces," by John Southward.

*** Particulars of Meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

The Electrician.

The Oldest Electrical Journal (1861—1878.)

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny.
Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone No. 6949. *Telegrams:* "ELECTRICIAN NEWSPAPER LONDON."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "Coutts and Co."

All Editorial letters to be addressed to the Editor.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as evidence of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices.*

New Volumes of "THE ELECTRICIAN" *commence in May and November.*

Subscription Rates.—The Rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	Year.	Half-Year.	Quarter.
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.

(Post free, payable in advance.)

TO ADVERTISERS,

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper Advertisements after Wednesday morning.*

OFFICIAL ANNOUNCEMENTS, AUCTIONS, *and* SMALL ADVERTISEMENTS *accepted up to 4 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "THE ELECTRICIAN" *Printing and Publishing Company, Limited, who are proprietors of the well-known* "ELECTRICIAN" SERIES *of Standard Electrical Works, and are Agents for all the leading publishing houses at home and abroad.* "THE ELECTRICIAN" SERIES *at present consists of—*

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. FLEMING, M.A., F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By OLIVER HEAVISIDE. Vol. I. Price 12s. 6d., post free 13s. *Vol. II. is in preparation.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. FLEMING.
VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. Price 7s. 6d., post free, 8s.
VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. FLEMING, M.A., D.Sc., F.R.S. 93 original illustrations, handsomely bound, price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. EWING, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. SNELL. 10s. 6d.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. GEORGE GORE. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. GEORGE GORE. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. KENNELLY and H. D. WILKINSON. Price 6s. 6d., post free.

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. WEYMOUTH. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By GILBERT S. RAM. Price 7s. 6d., post free 8s.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. GEIPEL and H. M. KILGOUR. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d. net, post free, 13s., abroad, 13s. 6d.

"THE ELECTRICIAN" PRIMERS. In Two Volumes. Price: Stout paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d. Abroad postage extra.

THE WORK OF HERTZ. By Dr. O. J. LODGE. Price 2s. 6d.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c By A. C. CURTIS-HAYWARD, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. BEAUMONT. Price 3s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. WILKINSON. *[In preparation.*

MOTIVE POWER AND GEARING. By E. TREMLETT CARTER. *[In preparation.*

NOW READY.—Vol. XXXV. of "THE ELECTRICIAN," bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

The published price of Volumes previous to Vol. XXXV. is 12s. 6d., post free 13s. 6d. Many of these Volumes are very scarce.

CHRISTMAS WEEK NOTICE.

"THE ELECTRICIAN" will be published as usual on Friday in Christmas week, but as the Offices will be closed on Wednesday and Thursday it will be necessary that Contributions, Correspondence, News Items and Advertisements should reach the Publishing Offices, 1, 2 and 3, Salisbury-court, Fleet-street, London, by, at latest, Tuesday's post.

THE REPORT OF THE BOARD OF TRADE EXPERT COMMITTEE.

The general body of electric supply undertakers must give the strong Committee appointed by the Board of Trade credit for wishing to meet their requirements, while endeavouring at the same time to ensure the safety of the public. The evident desire of the Board of Trade to placate the central station industry is shown by the granting of the two following important concessions to continuous current undertakings:—

(1) The Committee inferentially suggest that a system of continuous-current electric supply shall be considered low pressure when the pressure in the distributing mains cannot at any time exceed 500 volts.

(2) They are also of the opinion that the Board of Trade may give provisional sanction to the earthing, at one point, of the neutral conductor on certain conditions.

Notwithstanding these important concessions to the requirements of the undertakers, we shall not be surprised if the remaining suggestions of the experts meet with considerable criticism, not only on account of their debatable nature, but because of the great importance that will inevitably be attached to these recommendations, in view of the high standing of their originators and the fact of their having appeared after the recent Conference, at which the general views of the undertakers were so very clearly expressed.

We are afraid the value of the first concession will, in the eyes of most central station engineers, entirely vanish if the following proviso, which the Committee suggest, be inserted at the end of Supply Regulation No. 6:—"Provided that no

Digitized by Google

change shall be made in the pressure of supply to any consumer in consequence of the issue of these Regulations, except with his consent." This proviso obviously puts it in the power of any one obstinate consumer in a district to prevent the undertakers reaping any benefit by increasing their pressure of supply to that district. In connection with this matter, it must be remembered that the important step Mr. BAYNES has initiated in inducing consumers to take the supply at double the ordinary pressure is only the first step towards greater economy in the cost of mains, and is of no advantage in itself to the undertakers, until every consumer in the district is also supplied at the higher pressure, for not until this is effected can the great economy due to the higher pressure in connection with the three-wire system be realised. Taking human nature as we find it in this year of grace, it is not very likely that this general consent to the change will be readily obtained. We must bear in mind that, as a rule, undertakers have no other inducement to offer than that of exchanging old lamps for new, also that higher voltage lamps are at present more expensive and less durable than the ordinary lamps in general use, and that there will probably be one or more black sheep in the general body of consumers who will see their chance of making themselves suddenly important by resisting the proposed change.

We are not at all clear as to the reasons which induced the Committee to make a very important distinction between the systems of bare and insulated conductors when they suggested that in the former case it should be stipulated "that no such conductor should be at a higher potential than 300 volts from earth." It seems to us that this stipulation is as essential in a continuously-insulated conductor system as in that with bare conductors, for it would be quite as possible for the public to get a 500-volt shock in the one case as in the other, should one of the outer mains be at earth potential. With either system of distributing mains it seems to us absolutely necessary for the Board of Trade to not only sanction, but to insist on, the earthing of the neutral at the same time that they permit the raising of the limits of low-pressure supply.

With regard to the Committee's suggestion that the Board of Trade be empowered to sanction the earthing of a system of conductors at one point on certain conditions, we were under the impression that there was less danger of electrolysis happening with a system of conductors in which the neutral is earthed at the several feeding points than at one point, such as the generating station. In the latter case it is obvious that should a fault occur on any part of the neutral in a distributing network, the difference of potential between the fault and the station may be quite sufficient to cause electrolysis, should an extreme want of balance on the two sides of the three-wire system occur; whereas, if the neutral be earthed at all the feeding points, it is hardly likely that there would be a greater difference of potential than one volt between the neighbouring pipes and earth, under any circumstances.

We expect great disappointment will be felt by the majority of central station engineers at the Committee's suggestion that the invidious distinction between alternate and continuous currents existing in the old regulations should be retained, and that the limit for the low-pressure alternate-current supply should be just half that for continuous currents, viz., 250 volts. We cannot imagine what has induced the Committee to believe that alternate currents are just twice as deadly as their more constant rivals. On theoretical grounds it may be argued that the fatal effect of an alternate current is proportional to the maximum value of the difference of potential that occurs in any one period; with this assumption, and assuming further the average wave-form met with in English practice, about 350 volts should be considered equally as safe as 500 volts continuous. But when the Committee recommend lowering this limit by another 100 volts it must be apparent that the thought of some other danger in connection with alternate currents was the cause of their being so seriously handicapped. We trust that the academic bugbear of statical effect on low-pressure mains was not responsible for this. Many practical men are under the impression that, quite contrary to the above theoretically greater danger of alternate currents, as many fatal shocks have arisen from contact with continuous-current circuits as with alternating ones; and, knowing from painful experience the deadly gripping nature of a continuous-current shock compared to the well-known kicking-off effect of an alternate-current one, they cannot see any reason for maintaining the old idea of the greater danger of alternate currents.

THE ELECTRIC ARC.

BY HERTHA AYRTON.

(*Continued from page 39.*)

ANALYTICAL TREATMENT OF FIG. 46.

Let E be the E.M.F. of a generator in volts, let r be the total resistance in ohms in the circuit, outside of the arc itself, let there be a P.D. of V volts between the carbons, and let a current of A amperes be flowing through an arc of l millimetres. Then, referring to Fig. 46 (p. 37 *The Electrician*, November 8th), E is represented by the distance between P and the axis of current, r by the ratio of the distance from P Q of any point on one of the resistance lines to its distance from the axis of P.D. This is the same thing, of course, as r being represented by the tangent of the angle between a resistance line and P Q. A is represented by the distance between any point at which a resistance line cuts a curve and the axis of P.D. and V by the distance between that point and the axis of current.

Then $$E = V + A r.$$

But from equation (4) (p. 420, *The Electrician*, July 26th),

$$V = a + b l + \frac{c + d l}{A},$$

therefore $$E = a + b l + \frac{c + d l}{A} + A r, \quad . \quad . \quad . \quad . \quad . \quad (7)$$

or $$A^2 r - (E - a - b l) A + c + d l = 0; \quad . \quad . \quad . \quad (8)$$

hence $$A = \frac{E - a - b l \pm \sqrt{(E - a - b l)^2 - 4 r (c + d l)}}{2 r} \quad . \quad (9)$$

Thus we find, as before, that with a generator of given E.M.F. two different currents, or one, or none may be sent through the arc. The conditions for the three cases in the equation are that $(E - a - b l)^2$ shall be greater than, equal to, or less than $4 r (c + d l)$, and these correspond with the conditions in the figure that the resistance line shall meet the curve at two points, at one, or not at all.

Since the value for A obtained by using the positive root in equation (9) is greater for any given length of arc than that obtained by using the corresponding negative root, it follows that the positive root will give values which correspond with right-hand points of intersection between the resistance line and the curve, while the negative root will give values that correspond with the left-hand points of intersection. As it has already been shown that these left-hand points can never be obtained in practice, it will not be necessary here to discuss the negative root of the equation, and therefore henceforward when equation (9) is mentioned it will be understood that the positive root only is alluded to.

As before, we shall for the present discuss only the case in which the E.M.F. of the generator is constant, and we shall consider what happens, first, when r is constant and l is varied;

Digitized by Google

next, when l is constant and r is varied; and finally, when r and l are both varied in such a way that A is constant. In equation (9), if A is to have a real value at all, $(E-a-b\,l)^2$ must be not less than $4\,r\,(c+d\,l)$ whatever A, E, r, and l may be. Taking the first case—r constant, *i.e.*, following one of the resistance lines in Fig. 46—evidently, with the positive sign before the root, A is greatest when l is least, diminishes as l increases, and is least when l is greatest—that is, A is a maximum when l is a minimum, and a minimum when l is a maximum if the resistance external to the arc is kept constant.

But, since the expression under the root cannot be negative if A is to be real, l is a maximum when

$$(E-a-b\,l)^2-4\,r\,(c+d\,l)=0, \quad . \quad . \quad . \quad (10)$$

for, since E is constant, $E-a-b\,l$ is smallest when l is greatest, and since r is constant, $r\,(c+d\,l)$ is greatest when l is greatest. Hence when r is constant the condition that A shall have only one value, which is the condition that the resistance line shall be a tangent to the curve, is also the condition that the length of the arc shall be a maximum, as was shown when the subject was dealt with graphically.

Since A has been shown to be a minimum when l is a maximum, it follows that the smallest current that can flow with a constant resistance in circuit when the E.M.F. of the generator is also constant is given by the equation

$$A=\frac{E-a-b\,l}{2\,r}. \quad . \quad . \quad . \quad . \quad . \quad (11)$$

These maximum and minimum values for l and A may be found in terms of E, r, a, b, c, and d, all of which are known.

For from equation (10) we have

$$b^2\,l^2-2\,l\,\{b\,(E-a)+2\,d\,r\}+(E-a)^2-4\,c\,r=0,$$

hence

$$l=\frac{b(E-a)+2\,d\,r\pm\sqrt{\{b(E-a)+2\,dr\}^2-b^2\,\{(E-a)^2-4\,cr\}}}{b^2}$$

$$\text{or}\quad l=\frac{(E-a)}{b}+\frac{2dr\pm\sqrt{\{b(E-a)+2\,dr\}^2-b^2\{(E-a)^2-4\,c\,r\}}}{b^2}.$$

But from equation (9) it may be seen that l cannot be greater than $\frac{E-a}{b}$ when the quantity under the root is zero, otherwise A would be negative. Therefore, in the last equation the *negative* sign must be used before the root.

The quantity under the root is

$$b^2\,(E-a)^2+4\,b\,d\,r\,(E-a)+4\,d^2\,r^2-b^2\,(E-a)^2+4\,b^2\,c\,r,$$

which equals

$$4\,r\,\{b\,d\,(E-a)+d^2\,r+b^2\,c\}.$$

Therefore

$$l=\frac{E-a}{b}+\frac{2\,d\,r-2\,\sqrt{r\,\{b\,d\,(E-a)+d^2\,r+b^2\,c\}}}{b^2}. \quad (12)$$

And, substituting this value for l in equation (11) we get

$$A=\frac{\sqrt{r\,\{b\,d\,(E-a)+d^2\,r+b^2\,c\}}}{b\,r}-\frac{d}{b}. \quad . \quad (13)$$

Hence, if the E.M.F. of the generator is known, and also the external resistance that it is desired to have in the circuit, the longest silent arc that can be maintained and the smallest current that will flow are found in terms of the known E.M.F., the known resistance, and the known constants depending on the carbons used.

For instance, let us take

$$E=48{\cdot}88 \text{ volts},$$
$$r=\ 0{\cdot}5 \text{ ohm}.$$

Then, from equation (12) we get

$$l=1{\cdot}35\text{mm}.$$

Also, from equation (13) we have A = 7·2 amperes.

Thus, with an E.M.F. of 48·88 volts in the generator, and a resistance of 0·5 ohm in the circuit external to the arc, the longest silent arc that can be maintained with the carbons in question is one of 1·35mm., and the smallest current that will flow is one of 7·2 amperes.

Next let l be constant and r variable, that is, let us follow the course of one of the curves for constant length of arc in Fig. 46. Then, of course, A will also vary, and will again be a minimum when equation (10) holds. But r will also be a maximum when equation (10) holds, since any value of r greater than $\frac{(E-a-b\,l)^2}{4\,(c+d\,l)}$ would make the quantity under the root in equation (9) negative. Hence we have for A a minimum

$$A=\frac{E-a-b\,l}{2\,r},$$

and for r a maximum

$$r=\frac{(E-a-b\,l)^2}{4\,(c+d\,l)}.$$

By combining these two equations we can obtain the following one for A in terms of known quantities only, r being already given in known terms,

$$A=\frac{2\,(c+d\,l)}{E-a-b\,l}. \quad . \quad . \quad . \quad . \quad . \quad (14)$$

Thus, when the E.M.F. of the generator is known, and it is required to maintain a silent arc of fixed length, the maximum external resistance that can be used, and the minimum current that can be maintained, are found in terms of the known E.M.F., the fixed length of arc, and the known constants of the carbons.

For example, let

$$E=58{\cdot}88 \text{ volts},$$
$$l=3\text{mm}.$$

Then, from equation (10) we have

$$r=1{\cdot}1 \text{ ohms}.$$

Also, from equation (14) we get

$$A=6{\cdot}28 \text{ amperes}.$$

Hence, with an E.M.F. of 58·88 volts in the generator, and a silent arc of 3mm. to be maintained, a resistance of 1·1 ohms is the greatest that can be placed in the circuit outside the arc, and a current of 6·28 amperes is the smallest that will flow.

Lastly, let r and l be both varied in such a way that A remains constant, that is, let us follow some such line as S R_1 R_2 R_3 in Fig. 46. Then, from the equation

$$r=\frac{E-a-b\,l+\sqrt{(E-a-b\,l)^2-4\,r\,(c+d\,l)}}{2\,A},$$

it is plain that r diminishes as l increases, and becomes a minimum when

$$r=\frac{E-a-b\,l}{2\,A},$$

—that is, when the quantity under the root vanishes—or

$$r=\frac{(E-a-b\,l)^2}{4\,(c+d\,l)},$$

which is also the condition that l shall be a maximum for a fixed value of r.

By combining the last two equations we can determine the minimum value for r and the maximum value for l in terms of the known quantities, when E and A are constant,

$$r=\frac{d\,(E-a)+b\,c}{A\,(A\,b+2\,d)}. \quad . \quad . \quad . \quad . \quad (15)$$

$$l=\frac{A\,(E-a)-2\,c}{A\,b+2\,d}. \quad . \quad . \quad . \quad . \quad (16)$$

Thus, when the E.M.F. of the generator is known and the current is fixed, the minimum external resistance that must be placed in circuit, and the maximum length of silent arc that can be maintained, are found in terms of the known E.M.F., the fixed current, and the known constants of the carbons.

For example, let us take

$$E=58{\cdot}88 \text{ volts},$$
$$A=10 \text{ amperes}.$$

Then from equation (15) we get

$$r=0{\cdot}56 \text{ ohm},$$

and from equation (16) we have

$$l=4{\cdot}2\text{mm}.,$$

which shows that if with an E.M.F. of 58·88 volts in the generator we wish a current of 10 amperes to flow, the smallest resistance that can be placed in the circuit outside of the arc is one of 0·56 ohm, and the longest arc that can be maintained is one of 4·2mm.

THE RATIO OF THE POWER EXPENDED IN A SILENT ARC TO THE POWER DEVELOPED BY THE GENERATOR.

The ratio of the power expended in a silent arc to the power developed by the generator is an important factor in determining the most efficient arrangement to use in maintaining an arc. We are now in a position to determine when this ratio of A V to A E will be greatest.

From equation (4) (p. 420, *The Electrician*, July 26th), and equation (7) we have

$$\frac{V}{E}=\frac{a+bl+\frac{c+dl}{A}}{a+bl+\frac{c+dl}{A}+Ar}. \quad . \quad . \quad . \quad (17)$$

Hence, whatever value l may have, $\frac{V}{E}$, and therefore, $\frac{AV}{AE}$, is greatest when Ar is least; but from equation (9) it is evident that Ar is least when

$$(E-a-bl)^2=4r\,(c+dl),$$

that is, when equations (10) and (11) hold. From those two equations we find that when $\frac{V}{E}$ is greatest,

$$Ar=\frac{c+dl}{A}. \quad . \quad . \quad . \quad . \quad . \quad . \quad (18)$$

Equation (18) gives a value for Ar, which holds when $\frac{V}{E}$ is as large as possible, for any given value of l. It is still necessary, then, to find what values of l and A make $\frac{V}{E}$ greatest. If we substitute $\frac{c+dl}{A}$ for Ar in equation (17), and multiply numerator and denominator by A, we get

$$\frac{V}{E}=\frac{(a+bl)A+c+dl}{(a+bl)A+(c+dl)+(c+dl)},$$

from which it is plain that whatever A may be $\frac{V}{E}$ is greatest when $c+dl$ is least—*i.e.*, when l is least.

Thus *the ratio of the power expended in a silent arc to the power developed by the generator is greatest when the arc is shortest*—that is when the length of the arc is zero if we preclude negative lengths, of the existence of which we have no proof.

To find what value of A makes $\frac{V}{E}$ greatest for any given value of l, we may put the last equation in the form—

$$\frac{V}{E}=1-\frac{c+dl}{(a+bl)A+2(c+dl)},$$

which shows that, for any given value of l, $\frac{V}{E}$ is greatest when A is as large as possible. But A is as large as possible for a silent arc of given length *when the arc is about to hiss*, so that the value of A when $\frac{V}{E}$ is greatest for any given length of arc must be found from the equation connecting l and A for all the points on the hissing curve $X_1 X_2 X_3$ Fig. 46 (p. 37, *The Electrician*, November 8th). *Hence the ratio of the power expended in a silent arc to the power developed by the generator is greatest when the arc is on the point of hissing.*

It is still necessary to find what value of E makes $\frac{V}{E}$ greatest when A and l are fixed, but this is easy, for

$$\frac{V}{E}=1-\frac{Ar}{E},$$

and it has already been shown that Ar must be as small as possible for $\frac{V}{E}$ to be as large as possible. Therefore evidently E must also be as small as possible, or *the ratio of the power expended in a silent arc to the power developed by the generator is greatest when the E.M.F. of the generator is the least possible.*

Since the experiments upon which the curves in Fig. 46 are founded, and upon which the above reasoning is based, were made with arcs of not less than 1mm. in length, and with solid carbons, it is impossible to be sure that the laws which have been shown to apply to these arcs would also be true for arcs of less than 1mm. and with cored carbons. We can, however, be quite sure of the following: *In silent arcs of from 1mm. to 7mm. with solid carbons, the ratio of the power expended in the arc to the power developed by the generator is greatest when the arc is shortest, when the current is the largest that does not cause hissing, and when the E.M.F. of the generator is the smallest possible.*

The equation to the curve $X_1 X_2 X_3$ I have found—as I shall show later on—to be

$$A=\frac{11{\cdot}66+10{\cdot}54\,l}{1{\cdot}17+0{\cdot}4146\,l},$$

which, put in the general form, is

$$A=\frac{c+dl}{e+fl}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (19)$$

where c and d have the values already used in other equations, and

$$e=1{\cdot}17,$$
$$f=0{\cdot}4146.$$

Thus we have the three equations (10), (11), and (19) connecting the four variables l, A, E, and r, when $\frac{V}{E}$ is a maximum, and hence, if circumstances determine any one of the four, the other three can be found.

It appears from what has gone before that the length of the arc is the most important variable to choose first in making any arrangement to maintain an arc, for we know definitely that that should be as small as possible.

The difference between the greatest value of $\frac{V}{E}$ with one length of arc and its greatest value with another is not, however, very large. For instance, for the carbons I used, with an arc of 0mm. the greatest value of $\frac{V}{E}$ would be 0·97, obtained with a current of 10 amperes, an E.M.F. of 41 volts, and a P.D. of 40 volts between the carbons. With an arc of 3mm. the greatest value of $\frac{V}{E}$ would be 0·95, obtained with a current of 18 amperes, an E.M.F. of 50 volts and a P.D. of 45·5 volts between the carbons. Hence, although the actual power consumed in the shorter arc (400 watts) would be less than half as large as the power consumed in the longer arc (819 watts), yet the ratio of the power expended in the arc to the power developed by the generator would be nearly the same—viz., 0·97 and 0·95—for the two lengths of arc when the largest non-hissing current was used in each case. But at the meeting of the Electrical Congress in Chicago in 1893 it was shown by Prof. Carhart that the ratio of candle-power to electric power supplied to the arc was a maximum when the P.D. maintained between the carbons was increased to a certain value, and independently by Prof. Ayrton, that this ratio of light to electric power was a maximum when the length of the arc was increased to a certain value. Hence, to decide what length of arc, current and E.M.F. should be used in order to insure the largest ratio of the light emitted to the power developed in the generator, it would be necessary to find what length of arc gave the greatest amount of light for the energy consumed when the current flowing was the largest that did not cause hissing, and we might then find out what resistance to place in the circuit, and what E.M.F. to use, from equations (10) and (11).

For example, let us suppose that the preceding considerations have led to an arc of 3mm. in length being chosen, and that the arc lamp is fitted with a series regulating coil, and supplied with current from a generator of constant E.M.F. With such an arc a current of about 18 amperes is the largest that can be used without hissing, and from equations (10) and (11) we find that the generator should have an E.M.F. of about 50 volts, and that the total resistance in the circuit outside the arc should be about 0·13 ohm.

The current actually used must not, however, be so large that an arc can have any tendency to hiss. Suppose, therefore, a normal current of 15 amperes is selected, and that when it

Digitized by Google

falls to 13 amperes, and the arc has increased in length to 3·2mm., the regulator begins to feed the carbons.

Then, remembering that the current that is to flow is no longer the greatest non-hissing current, but something less, and that E and r are to be the same whatever the current and length of arc may be, we must put

$$A = 15$$
$$l = 3$$

and also

$$A = 13$$
$$l = 3{\cdot}2$$

in the general equation

$$A = \frac{E - a - bl + \sqrt{(E - a - bl)^2 - 4r(c + dl)}}{2r}$$

in order to find E and r. In this way we shall find that E must be 55·5 volts and r must be 0·5 ohm.

Hence we have V or $E - Ar = 55{\cdot}5 - 7\,5$

and

$$\frac{V}{E} = \frac{48}{55{\cdot}5}$$
$$= 0\,87.$$

Thus with these carbons, if a silent arc of 3mm. be maintained with a current of 15 amperes flowing, the arrangement can be made so efficient that 87 per cent. of the power developed by the generator will be used in the arc, and only 13 per cent. will be wasted in the resistance outside the arc. This total resistance external to the arc includes, of course, the resistances of the generator, the leads, and the coil of the regulator, so that it might be practically impossible to make it as small as 0·5 ohm, but the greatest value of $\frac{V}{E}$ would in that case be obtained by making this outside resistance as near 0·5 ohm as possible.

Without, however, for the moment considering the new circumstance that this impossibility of using a small enough resistance introduces into the problem, we may sum up the ideal conditions to be striven for in an arc, in order that the ratio of the power expended in the arc to the power developed by the generator may be as large as possible. They are:

(1) That the arc should be as short as possible.

(2) That the current should be the largest that will certainly give a silent arc.

(3) That the regulator should start feeding the carbons for as small a diminution of current and as small an increase in the length of the arc as possible.

(4) That the E.M.F of the generator should be the smallest that will send this diminished current through the increased length of arc.

(To be continued.)

THE NEW FRENCH ATLANTIC CABLE.

The following is an abstract of the Agreement which has been entered into between the French Government and the Compagnie Française des Câbles Télégraphiques in connection with the proposed new cable from Brest to Cape Cod. This Agreement is embodied in a *projet de loi* which has just been submitted to the French Chamber.

By Article 1 the Compagnie Française undertakes to run from Brest a cable connecting France directly with the United States, and landing near Cape Cod, and to work and maintain this cable for 30 years, the cable to be prolonged to New York by special land or submarine lines independent of those which the Company possesses at the present moment. The Company further undertakes to work the existing cables belonging to it between Brest and St. Pierre, St. Pierre and Cape Cod, St. Pierre and Canso, and to maintain all these cables in such a condition that they can act as auxiliaries until the transatlantic cable mentioned in Article 9 is laid. The Company further undertakes, within two years from the final signature of the Agreement, to manufacture and lay an independent cable connecting the network which the Company possesses in the West Indies with its transatlantic system.

By Article 2 it is laid down that the period covered by the Agreement shall be 30 years, and that the authorisations now granted do not confer any exclusive right.

By Article 4 it is laid down that the new cables are to be entirely manufactured in factories situated on French territory; they are to be laid by French *personnel* in vessels one of which at least is to be French. The old and new submarine cables belonging to the transatlantic and West Indian networks are to be maintained by French boats manned by French crews, and all cable intended for repairs is to be made in France.

By Article 5 the Company undertakes to keep its offices in France and only to have French directors. It may not cede any rights conferred upon it by the present Agreement, nor let any lines referred to therein, nor amalgamate its interests with those of any other company, either French or foreign, without the express consent in writing of the French Government. It further undertakes not to take part, either directly or indirectly, during the time which the Agreement is in force, in any line which may reduce the traffic passing over the transatlantic lines referred to in the first clause, without the express permission of the French Government given in writing.

Article 6 —"The French Government grants to the Company, in return for laying, maintaining and working the cable between Brest and Cape Cod, an annual subsidy of 800,000fr. (£32,000) for 30 years from the date on which the cable and the line joining it to the West Indian system come into operation. When the gross receipts arising from the transmission of telegrams by the transatlantic cables of the Company amount to more than 1,650,000fr., two-thirds of the excess shall be applied to the reduction of the subsidy alluded to in the first paragraph of the present clause. Consequently the payment of the subsidy will be suspended during those years in which the receipts reach 2,850,000fr."

Article 7.—"When the gross annual receipts referred to in the preceding article shall exceed 2,850,000fr., the Company undertakes to devote 50 per cent. of the excess to the formation of a special reserve fund. This fund will be invested under the control of the Minister of Posts and Telegraphs in agreement with the Minister of Finance, in French *rentes*, in shares guaranteed by the French State, or in French municipal or departmental stock, or in French railways, or in the Crédit Foncier de France. The interest accruing is to be annually added to the fund. This special fund is to be allocated as follows: (1) To the diminution of the subsidy if it has once more to be paid; (2) to the improved working of the cable and the extension of the Company's system, especially to the manufacture and laying of the transatlantic cable referred to in Clause 9: "In no case may it be employed without the permission in writing of the Minister of Posts and Telegraphs. The proportion of the surplus referred to in the first paragraph of the present clause, which is to be devoted to the reserve fund, will be reduced from 50 per cent. to 33 per cent. from the moment when the transatlantic cable, referred to later, has been brought into operation."

By Article 8 the Company is empowered to issue bonds for a sum not exceeding 20,000,000fr. (£800,000). The State subsidy is to be specially allocated to paying the interest and to redeeming of these bonds, and is to be supplemented by such proportion of the receipts as may be necessary to complete the total sum.

Article 9.—"While the present Agreement lasts, the Administration of Posts and Telegraphs will send, by preference, over the lines of the Company all telegrams for North America and the West Indies, for which the senders have not designated a special route, on the condition that the rapidity of transmission is equal to that of other routes, and the tariff is not higher. On its part, the Company will send, by means of its transatlantic lines, all European traffic received by it, and will direct it on to the points served by its cables, unless the senders have designated another route, and unless, owing to interruption or other causes, transmission by its lines would be prejudicial to the rapid and regular expedition of the telegrams concerned. When the gross annual receipts referred to in Clause 6 attain, during two consecutive years, 4,500,000fr., the French Government may demand that the Company shall lay, within eighteen months, the new transatlantic cable intended to replace the existing Brest-St. Pierre-Cape Cod cable. The route of this cable will be determined in agreement with the French Government. It is to be constructed upon the same terms as the direct cable, and it will be worked under the same regulations.

By Article 10 it is laid down that State telegrams shall enjoy a reduction of 75 per cent. upon the ordinary tariff between France and the United States, and in the case of the other lines of the Company, it shall receive at least as great a reduction as that granted to any other foreign country, and in no case is the reduction to be less than 50 per cent.

By Article 11 the Company undertakes to deposit caution money within one month from the signing of the Agreement to the amount of 400,000fr., the money to be restored to the Company upon the new transatlantic cable coming into operation.

By Article 12, the Company renders itself liable to a fine of 1,000fr. per day, in case of delay in carrying out the lines contemplated in the Agreement, and if the delay exceeds six months, the Agreement may be cancelled by a decree of the Minister of Posts and Telegraphs, and the State may confiscate the money.

By Article 13, a fine of 1,000fr. per day is imposed in the event of an interruption lasting more than 90 days, the fine to be com-

Digitized by Google

menced from the first day of the interruption, provided always that the Company is unable to plead *force majeure*. A fine of 500fr. is to be imposed in the same way in case of interruption of any of the Brest-St. Pierre, St. Pierre-Cape Cod, St. Pierre-Canso cables. This fine is to be increased to 1,000fr. per day, to count from the first day of interruption, if these cables are not repaired within nine months.

Articles 14, 15 and 16 deal with the governmental control and traffic organisation, &c.

Article 17.—"The Minister of Posts and Telegraphs may cancel the present Agreement and take over the operation and maintenance of the transatlantic cables in the following events :—

(1) The interruption of the Brest-Cape Cod or the junction cable for more than a year, no case of *force majeure* being made out.

(2) If, after the laying of the cable referred to in Clause 9, the two new transatlantic cables be simultaneously interrupted for more than three months, except in the case of *force majeure*.

(3) The non-observance of one of the essential clauses of the present Agreement, such as 4, 5 and 9 (second paragraph).

Articles 18 and 19 deal with the settlement of disputes between the Company and the French Government, and the stamping of the Agreement.

The Agreement is dated Paris, July 2, 1895.

INSTITUTION OF ELECTRICAL ENGINEERS.

The following members constitute the Council of the Institution of Electrical Engineers for the year 1896. New members of Council, or members occupying new offices on the Council, have their names in italics :—

President.

Dr. John Hopkinson, M.A., F.R.S.

Vice-Presidents.

Sir David Salomons, Bart., M.A.	Robert Kaye Gray, M.Inst.C.E.
Sir Henry Mance, C.I.E., M.Inst.C.E.	*Prof. S. P. Thompson, D.Sc., F.R.S.*

Ordinary Members of Council.

Major A. H. Bagnold, R.E.	William E. Langdon.
Frank Bailey.	Augustus Stroh.
G. von Chauvin.	*Henry Edmunds.*
W. B. Esson.	*Prof. J. A. Fleming, M.A., D.Sc., F.R.S.*
S. Z. de Ferranti.	
Prof. A. B. W. Kennedy, LL.D., F.R.S., M.Inst.C.E.	*Dane Sinclair.*
	J. W. Swan, F.R.S.

Associate Members of Council.

Capt. W. P. Brett, R.E.	*Sydney Morse.*
H. W. Miller.	

It was announced in the course of the reading of the Annual Report that the Institution Premium had been awarded to Mr. Mark Robinson for his Paper "On the Recent Development of the Single Acting High Speed Engine for Central Station Work"; the Paris Electrical Exhibition Premium being awarded to Prof. J. A. Ewing for his Paper, "A Magnetic Tester for Measuring Hysteresis in Sheet Iron"; and the Fahie Premium to Mr. J. E. Kingsbury for his Paper, "The Origin and Development of the Telephone Switchboard." A Student's Premium was awarded to Mr. Eborall for his paper on "Single-Phase Alternate-Current Motors."

HOW TO THROW ON A RAILWAY GENERATOR.*

Many subordinates in power stations who are striving to climb higher do not know how to properly throw a railway generator on to the line, or to throw it off when the run is ended. Railway generators are usually arranged for connection to the switchboard in one of three ways. Some are provided with a double-pole switch, and the equalisers are permanently connected together. Some have a triple-pole switch and an equaliser bar, while others have three separate switches. These three methods of connection are shown in Figs. 1, 2, and 3, and in each case it is necessary to follow a slightly different method in throwing the machine on the line. In any case the following precautions should be carefully observed :—

A generator must not be thrown on a set of 'bus bars to which several dynamos are supplying current unless the voltage of that generator is equal to that of the 'bus bars. A large generator when thrown into multiple with a small generator will operate the latter as a motor unless the larger generator has a slightly lower voltage. If several small generators are connected on the line, and their combined capacity is greater than that of the large one, this precaution need not be observed. It should be remembered that when there are two machines the 'bus-bar voltage is always that of the generator of the greater capacity. Therefore this should not be high enough to overpower the smaller machine. It is wise to have the voltage slightly lower at the time the machine is thrown in.

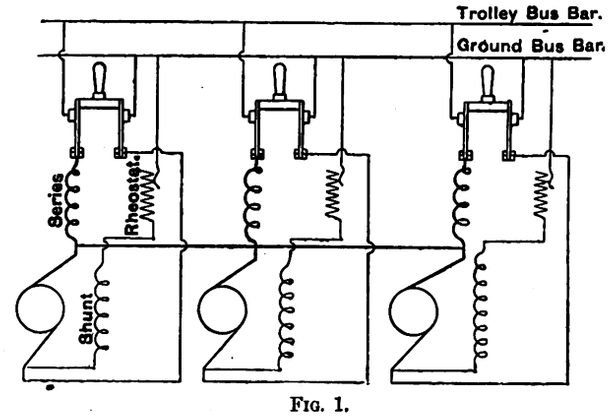

Fig. 1.

The method of procedure in case of Fig. 1 is as follows: With the brushes raised start the generator, being sure that the oiling devices are working properly. When full speed has been attained, see that all switches are open and then let down the brushes, being careful to adjust them so that they run without cutting or "squealing." Then step to the switchboard. Throw in the equaliser

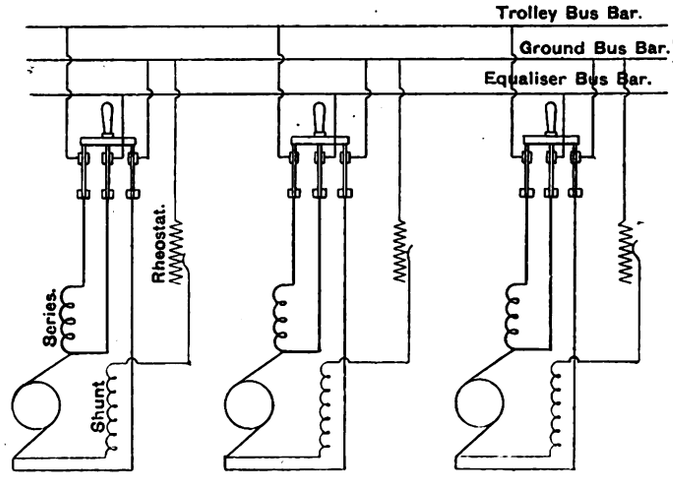

Fig. 2.

switch if there is one, and give the rheostat a turn, and let the machine build up. While the machine is building up consult the ammeter, which gives the total load on the station, and then make some such calculation as this: "I have at present a total load of 800 amperes. When this new machine is thrown in the combined

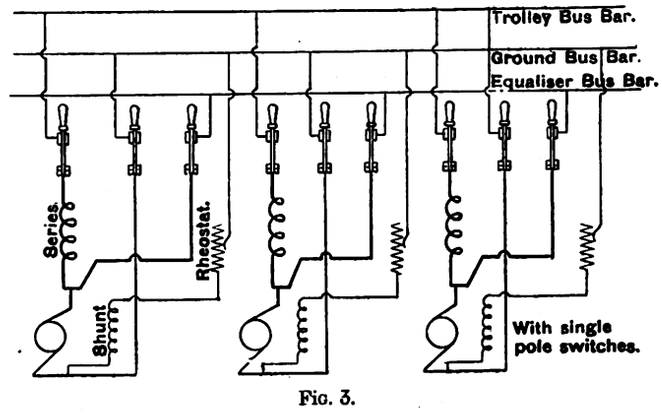

Fig. 3.

capacity of all the machines running will be 1,200 amperes. Therefore eight-twelfths of the capacity of the machine is the load it should carry.

The capacity of the machine is 250 amperes; $\frac{8}{12}$ths of 250 is 167 amperes approximately. This, then, is the load which the generator

* From the *Electric Railway Gazette* of New York.

Digitized by Google

should carry. Probably before this calculation is finished the machine is ready to be thrown in. Bearing in mind the precautions already mentioned, bring the voltage of the machine up to the proper amount. Proceed slowly. It takes time for a machine to regulate. After the desired voltage has been reached, and shows no tendency to change, throw in the double-pole switch. Attention should at once be directed to the ammeter. By means of the rheostat adjust the current to 167 amperes, in accordance with the previous calculation. It will be found that the instrument will now readily respond to the motions of the rheostat, while the voltage depends on the voltage of all the machines, and therefore has passed out of control.

With the three-throw switch the procedure is exactly the same, only the equaliser is thrown simultaneously with the other terminals.

With the three separate switches the controller is a little more convenient. The equaliser should be thrown first, and then the switch on the positive side. All coils and instruments are by common custom placed on the outgoing wire, hence the series coils are thrown in multiple with the series coils of other machines, and are receiving a current which provides an initial excitation for the field-magnet. This prevents annoying refusals of the machine to build. After the machine has acquired the proper voltage, throw the positive switch, observing the same precautions as in the other cases.

To shut down a machine at the end of a run, stand with one hand on the main switch, and give the rheostat a slight turn, which will tend to weaken the field. The load will gradually come off the machine, as will be shown by the ammeter. Watch this instrument, and when the reading denotes about one-fourth load, throw the main switch at once. This permits the load to be gradually thrown off, and the danger of racing and wrenches to both dynamo and engine are avoided.

RESEARCHES ON ALTERNATE-CURRENT ARCS.*

BY H. GÖRGES.

These investigations were carried on during a number of years at the Charlottenburg works of Messrs. Siemens and Halske. They were conducted by Messrs. Oelschläger, Greisser and Dr. Michalke.

It is well known that with a continuous current the positive carbon assumes a much higher temperature and greater luminosity

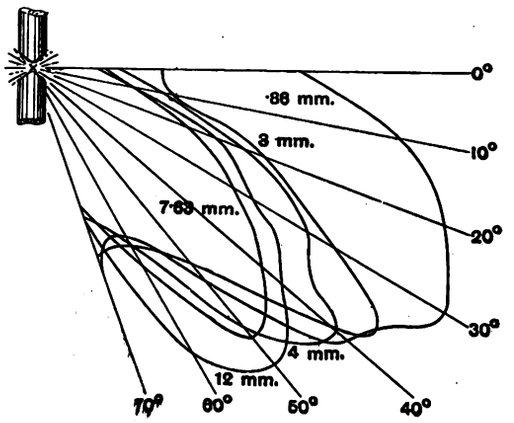

FIG. 1.

than the negative carbon. With an alternate current the upper and lower carbons are positive in turn, and the stronger light is alternately thrown upwards and downwards. The limit of perception of the flickering differs subjectively and lies at about 60 periods per second. At 40 per second it is still unendurable, at 50 it is barely perceptible. It is less seen when the arc is surrounded by a ground glass globe and when the lamp is at a greater distance. A reflector of the Helios pattern, placed close above the arc, reduces the flickering considerably by reflecting the impulses of the lower carbon and sending 100 light-impulses to the eye instead of 50. The length of the arc largely influences the luminosity with the same expenditure of energy. It is evident that each carbon takes away much of the light by creating its own shadow. Hence the arc should not be made too small. On the other hand, the temperature of the ends is highest when they are as close together as possible. Fig. 1 shows how the brightness decreases with an increasing length of arc, the energy remaining the same. The curves represent the light per watt for a 12-ampere lamp; 1mm. represents ¼ Hefner candle. The numbers at the side of the curves represent the length of arc. The shape of the current curve has also a great influence upon the character and behaviour of the arc. With some machines the curve may be altered by simply changing the connections. For the following experiments one of Siemens and Halske's "drehstrom" machines was used, which could be connected at will in triangle or in star. Taking one branch only, a flat curve was obtained (Fig. 2, I.). On connecting in star, the superposition of the curves due to both branches produced a new curve somewhat resembling the sinusoidal curve (Fig. 2, broken curve). Finally, on connecting the two branches in series in the opposite direction to the connection in star, a pointed curve is obtained (Fig. 2, II.), which is not adapted for practical use since the output of the machine is too small.

The noise made by the arc depends greatly upon the current curve. By the periodic heating and expansion of the carbon points and of the air between them, notes and noises are produced. They always occur in the alternate-current arc. With a sinusoidal curve the note is soft and musically pure; with suddenly varying curves, overtones and impure noises appear, which are perceived as a more or less loud humming. This becomes louder as the length of arc, the number of alternations and the current increase. With a greatly extended arc it sounds almost like a trumpet. The noise is much diminished by glass shades, and becomes almost imperceptible in the case of sinusoidal currents.

The temperature of the carbon points, and hence also the luminosity, is essentially determined by the energy consumed in the arc. With high frequencies the amount of light is probably independent of the form of the curve. But with the frequencies actually employed the luminosity, as has been shown in detail by Prof. Wedding and Dr. Rössler, increases with the flatness of the curves.

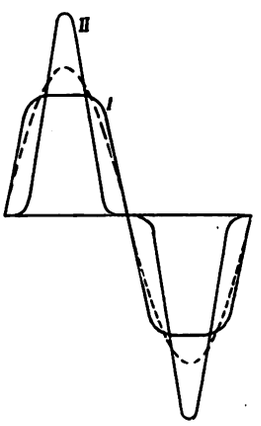

FIG. 2.

Our own measurements bear out this result. We found for a 12-ampere lamp, with a frequency of 50 per second, for a flat and a pointed curve respectively,

—	Flat curve.	Pointed curve
Mean pressure	33·5 volts.	25·7 volts.
Maximum for 1 volt mean pressure	1·19 „	1·93 „
Maximum for 33·5 volts mean pressure	40 „	...
Maximum for 25·7 volts mean pressure	...	49·2 „
Displacement of phase between current and lamp pressure	19deg.	19deg.
Mean length of arc	2·9mm.	3·1mm.
Mean spherical intensity per watt	0·960 Hefner units.	0·796 Hefner units.

The higher efficiency of the flatter curves may be accounted for in two ways. With pointed curves a short period of large current is followed by a longer time of small current. During the latter period the carbons will cool considerably. But with decreasing temperature the luminous radiation also rapidly diminishes. The intervals of small current will therefore have little influence on the luminous output. But quite a different explanation may be given. The eye perceives a mean luminous intensity when the frequency is high enough. If we imagine the light curves really traced in a system of co-ordinates, the mean algebraic value may be the same for flat and pointed curves. But perhaps the eye measures another mean value, just as the dynamometer does not measure the algebraic mean of the current intensity.

To obtain an objective record of these luminosities, a disc covered with sensitive paper was attached to a motor, and covered with a stationary disc provided with a radial slit. The result was a photographic tracing of the variations of luminosity during each revolution of the shaft. It was found that the sensitive paper is capable of recording as many as 300 alternations of light per second, where the eye sees nothing but a steady glow. Several of the traces thus obtained are reproduced in the Paper.

* Abstract of address delivered before the Elektrotechnische Verein.

By a somewhat similar arrangement the experimenters were also able to apply the photometer direct to the light caught intermittently at a certain phase, and to determine the curves of current and pressure at the same time. The results of these measurements

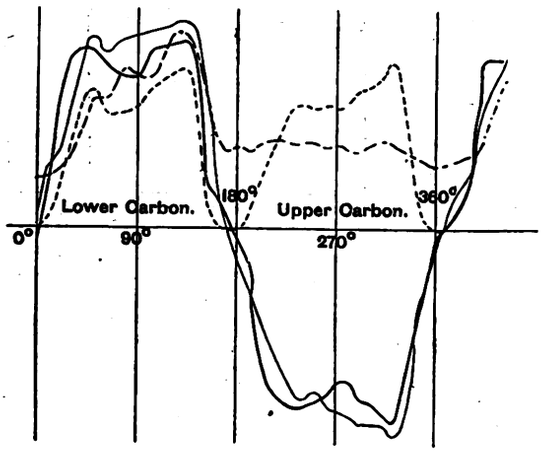

Fig. 3.—Current ——— Pressure ——— Light —.—.— Energy — — — —

are shown in Figs. 3, 4 and 5. The rays measured are those projected at an angle of 35deg. below the horizontal. During the period of large current an accumulation of heat takes place, which
